TABLE OF CONTENTS

EDITORIAL

BEFORE this reaches the reader the name of the Director of the Bureau of Mines doubtless will have been announced. Whoever he may be, he will have our good wishes and hearty co-operation, as he will of mining engineers generally.

FREIGHT rates on lead ore from the Coeur d'Alene district to Carnegie, Pennsylvania, have been reduced to $11.40 per ton, 95 per cent of the rate to the Atlantic seaboard, as a result of complaint made by the Pennsylvania Smelting Company.

PRODUCTION in the Goldfield district during the first half of the year has amounted to more than $7,000,000. Dividends declared have totaled $5,443,647, of which $3,664,098 has been paid, and the balance, $1,779,549 will be paid July 31, it being the third consecutive quarterly payment of 50 cents per share made by the Consolidated Mines Company.

CANANEA furnace practice is discussed by Mr. Courtenay De Kalb on another page of this issue with a wealth of detail that is seldom available to the writer of technical papers. Mr. L. D. Ricketts has made the profession his debtor in many ways in the course of his active and honorable career, but in no way more than the frankness with which he has given out technical data. In this he sets an excellent example, and it is a great pleasure to acknowledge our own indebtedness.

SCRANTON, Pennsylvania, being built largely over coal mines, has been endangered in part by caving in the old workings. Popular excitement over the real and fancied dangers has become so great that it is now proposed to have a thorough survey of the ground under the city made by Mr. William Griffith and Mr. Eli T. Conner. It is further planned to submit the results of this survey to an advisory board consisting of Messrs. John Hays Hammond, W. A. Lathrope, Lewis B. Stillwell, D. W. Brunton, and R. A. F. Penrose, Jr., for study and recommendation. It is to be hoped that this plan may be carried through, as it would be sure to result in a clear statement of actual conditions and sound recommendations.

IDAHO has been particularly vociferous, in Washington at least, in complaints against the large areas included in National Forests in that State. It is interesting, therefore, to find the Miners' Protective Association of Pine Creek entering an emphatic protest over threatened depredations by timber companies in territory in Shoshone county just outside a reserve. Our sympathies are wholly with the miners. In any mineral country the timber should

be reserved first of all for use in developing the mines, and attempts to get title to land for the purpose of harvesting the timber, without which it is impossible to develop the mineral claims, call for prompt investigation. In the National Forests the miners have in places and at times been put to unnecessary expense and inconvenience by the Forest Service, but incidentally they have been fully and promptly protected in just such cases as the one cited. Apparently here is one case where the Forest reserve includes too little rather than too much territory.

KOREA is a country of large and little-developed mineral resources, despite a gold output now amounting to over $3,000,000 yearly. Near Wiju it is said that nearly 600 tons of gold ore containing approximately an ounce per ton, is now being crushed in primitive wooden stamp-mills, and the possibilities of dredging at various points on the peninsula are just coming to be recognized. While some of the largest financial houses in Japan are interested in Korean mines, there is need for more capital than is locally available. Relations between Americans and Japanese have been especially friendly in Korea.

Fourth of July

Monday will be the Fourth of July, and throughout the United States, a holiday. To many miners, unfortunately, it is merely a day on which to get drunk, and to many managers, one when the mine does not ship. The good old Colorado rule was a three days holiday—one to get drunk, one to stay drunk, and one to sober up—and the mid-summer spree was as regular as that which marked midwinter at Christmas. Happily not all miners devote the day to this purpose. In many camps there are 'Grand Picnics' followed by equally 'Grand Balls' in the evening. Someway there never was a picnic or ball in a mining camp that was not 'Grand'—at least in the announcements. The picnics are the more interesting. The sports take character from the everyday work of the men, and rare records are made in 'single-jack' and 'double-jack' contests, while teamsters show a marvelous skill and an unwonted energy in loading, unloading, and driving contests. In Gilpin and Clear Creek counties of Colorado, the day is one for annual contests between volunteer fire brigades, and the knights of the ladder and hose cart have doubtless been practising for weeks. In Nevada this year all roads will lead to Reno and long strings of cars will stand on the siding while the 'Hope of the White Race' battles with the 'Pride of the Blacks' to determine whether the miners or the Pullman porters shall have the more legitimately obtained headaches on Tuesday. In other States and in other lands, in thousands of cities and towns, wherever in fact nine Americans can get together, the Umpire will hold up his fingers and say: "Strike two, ball two," and there will be that answering yell: "Now then, Shorty, a three-bagger!"

It is everywhere a day of sport. Many a tunnel and shaft-house will be locked, and many a lone watchman will share his lunch Monday with the chipmunks. In many a lonely underground station the foreman will throw the switch and watch the pumps, for the foreman, of course, is older and already married and realizes that Tom the pumpman must have this day off if he is to keep the blacksmith on the other mine from 'cutting him out' with his girl. Many a miner will shoulder his rod or his gun and start off up the canyon with a wary eye for fish or game, for this is the day for taking that long neglected and much planned fishing or hunting trip. Happily as some such eats his lunch a bit of 'ledge matter' may catch his eye and a second Stratton may locate another Independence, ushering in another Cripple Creek! Whether, however, we hunt, fish, play ball, go to picnic or dance, whether we do any of these or merely with the wiser ones gather our families together and dream in the shade while tired muscles relax and from the blue sky and the yellow sunshine we breathe in health and strength, let us take a moment at least for thought of the significance of the day.

Our forefathers justified the first Independence day by physical combat with the British. That lies so far in the hazy past that we look on it now as merely a family quarrel. We must justify our own Independence day. Unless our National life, measured in its largest sense, be better for the independence of our country, we fail to give reason for standing out alone. We must still contest with the British, though this has become a friendly strife for supremacy in professional success, in governmental efficiency, in social betterment. Are we, let us ask ourselves, now justifying our independence? So long as we may honestly answer this in the affirmative, we may fairly celebrate the Fourth of July; when we cannot, it is time to mend our way or petition for re-admission to the British Empire.

Prices of Spelter

Spelter sold last in St. Louis at less than 5 cents per pound; a price which it has not touched since the new tariff on zinc ores went into effect. At present prices, and with Joplin ore on a $40 basis, there is no margin for the smelter, so furnaces must be closed unless improvement come quickly. The limited demand for spelter seems to be a reflection of the generally unsatisfactory condition in the metal trades. Over 60 per cent of the consumption of spelter in this country is for galvanizing, while 17 per cent of the metal is used in making brass. Decreased consumption of iron and copper must inevitably affect the demand for spelter, and with large stocks of metal now visible, prices are peculiarly sensitive to any decrease in buying. At the same time crop prospects are good and the railways anticipate heavy traffic this fall. That means increased demand for the metals, and it is not likely that spelter, at least, will go lower than at present. Late in 1907 the market for lead was sustained almost wholly by the farmers who, amid all the uncertainties of that disastrous year were busy re-painting their buildings oblivious of the much discussed higher cost of living. It is possible that the farmer by extending his barbed wire fences this fall, may perform an equally valuable service for the zinc miners and smelters.

The New Railway Law

The railway bill finally agreed upon in conference and enacted by Congress is an important and complex measure. It will take many court decisions to determine, not perhaps what Congress purposed, but what it enacted. The final effect of the new law, as relates to commerce and industry, is even harder to forecast. The passage of the law was bitterly contested and it represents compromise; but it is a compromise based on study and not on log-rolling. Few recent enactments of Congress have been more fully and more intelligently debated, and while in its final form it contains nearly all of the features of the law proposed by the President, it has none the less been re-built from terminus to terminus, to its own great advantage. The two leading features of the act are the creation of a Commerce Court and the establishment of the principle that a proposed new rate must be justified before going into effect. Minor changes are the extension of the authority of the Interstate Commerce Commission to cover telegraph, telephone, and cable companies; provision that the Attorney-General shall prosecute cases in place of the Commission; an attempt to revive the 'long and short haul' principle; provision that the Commission may establish rates on its own initiative; prohibition against carriers divulging information regarding shipments that may be used to the detriment of the shipper; requirement that charges applicable to a proposed shipment be quoted in writing; recognition of State laws and courts; and provision for a special Commission to investigate the feasibility of supervising the issue of railway securities. Among the things left out are, (1) any provision for legalizing combinations of railways, and (2) any for making a physical valuation of the railways as one element in rate making. The first was urged by the Administration, and the second by Mr. R. M. La Follette and the 'Insurgent' senators. We think the value of the bill would have been increased by their addition.

Despite various uncertainties as to interpretation of details of the new law, the latter can unhesitatingly be commended. The Commerce Court is well constituted and should prove an important aid in securing reasonable and just railway regulation. Specialization has its place in the work of the judiciary just as it has in mining engineering, and it is wrong that cases should be taken, either by the Government or the railways, to the particular circuit court most likely to give a favorable interpretation. The law should be uniform, and the new court, ranking with the Circuit Courts of the United States and presided over by Judges transferred to it from them for terms of five years each, should give a correct and stable interpretation of the law. The establishment of the Commerce Court will not only relieve the Circuit Courts, but in connection with other changes will also to some extent remove the Interstate Commerce Commission from the anomalous position of being both prosecutor and judge. The new law imposes heavy additional burdens on the Commission and the aid of the Commerce Court, therefore, is most important.

The basis of rate making unfortunately remains unfixed, and the method of comparisons is still to be used, with the old stipulation that rates must be 'reasonable'. It is to be hoped that the new commission will devise some effective method of supervising the issue of railway securities and ascertaining the present value of railway property. These matters rest at the bottom of the agitation against higher railway rates. The objection is not against paying a fair rate on a real investment, but against rates fixed to pay an unknown rate based on equally mysterious and evasive figures as to actual investment. The railways maintain that they must raise rates in order to pay suitable dividends on outstanding securities and thus maintain their credit so as to borrow additional sums necessary for improvements and additions. When the enormous sums constantly borrowed by the railways are taken into account the question forces itself as to whether the companies would not do better to make poorer showings as to earnings and borrow less money; in other words replace old locomotives and rails out of earnings instead of issuing bonds or stocks upon which interest must be earned. The Santa Fe has been widely quoted as falling behind in net, despite a marked increase in gross earnings. The reason seems to lie in the fact that a larger amount than usual is being spent on betterments; a very sensible procedure. If the railways cannot live on their present rapidly growing income, why add to the expense by fixed charges due to repeated borrowings? An example of the confusion in statements now made to the public may be instanced the contention of the shippers committee that from 1897 to 1907 the net income per mile on American railways had increased 345 per cent, and the objection by Mr. E. P. Ripley of the Santa Fe that the real increase was 83 per cent. The facts seem to be that the 'income from operation' increased 83 per cent, the figure quoted by Mr. Ripley, but that 'net income from all sources' increased 345 per cent as shown by the shippers. The difference in figures is due mainly to the re-investment of earnings in subsidiary lines.

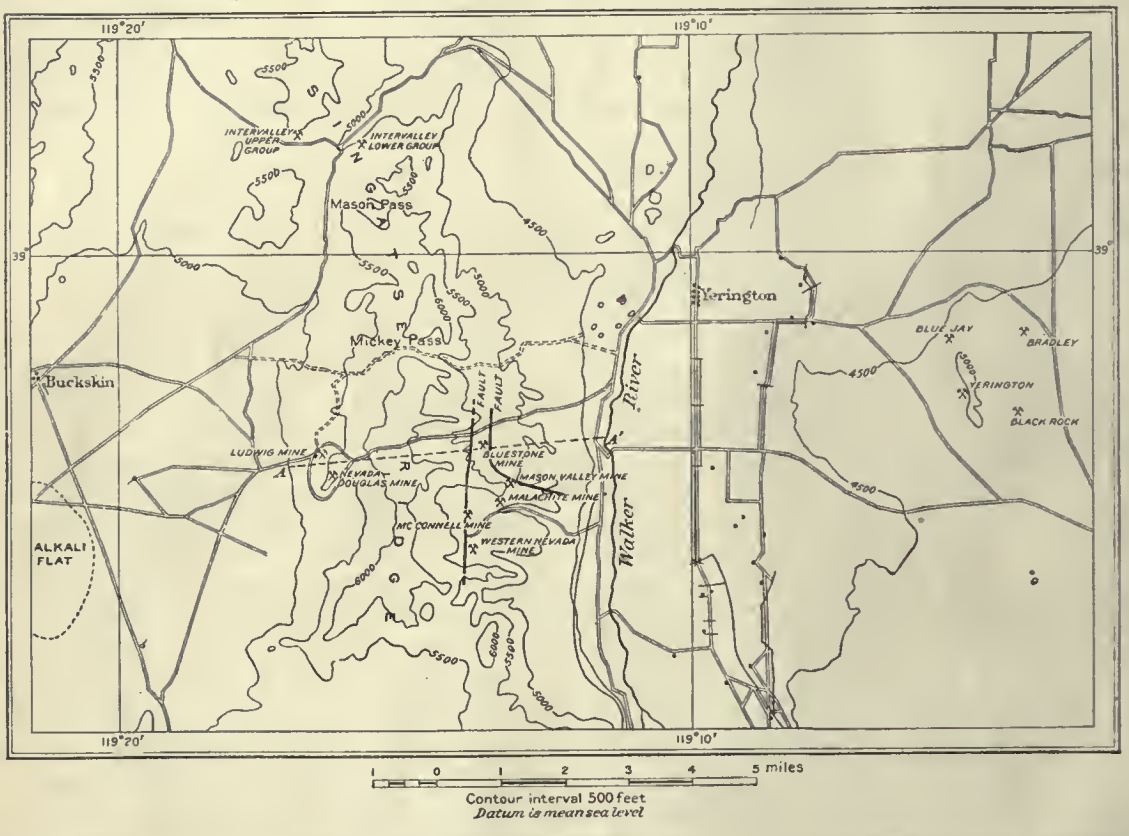
Much has been said recently about 'interference with business by politicians', and even the usually sane and careful *Railway Age Gazette* charges the new law to a desire for votes on the part of members of Congress. We think this a superficial view. The impelling force toward the new legislation must be sought in deeper-lying causes. The significant feature is the public opinion back of this legislation. The railways are not being forced into politics, it is because they have been in politics that the protest has come. It is part of the movement against 'Government by special interests'. As transportation companies, Americans are universally proud of their railways; it is the activity of the railway managers in other directions which makes people suspicious and unwilling to leave in their hand matters, such as fixing rates, that are vital to the public as well as the railways. No one ever had anything but good words for Mr. Harriman as a railway builder and re-builder, but Mr. Harriman, as a manipulator of railway stocks and bonds, is responsible for much of the present insistence that the public shall control the railways rather than the reverse.

The Yerington Copper District

By Jay A. Carpenter.

The Yerington copper district is in the south end of Lyon county, Nevada, 25 miles from the California line and 50 miles southeast of Reno, Nevada. By railroad it is reached by taking the Hazen-Goldfield branch of the Southern Pacific system to Wabuska, and changing there for a short ride of 14 miles to the south on the recently completed standard gauge Nevada Copper Belt railroad. The town of Yerington, from which the district derives its name, is on the east side of the Walker river in the centre of the prosperous and well cultivated Mason valley. This valley is thirty miles long and seven wide, with nearly 50,000 acres under cultivation and an additional equal amount capable of being cultivated when the increased market for farm products warrants the building of storage reservoirs for the flood waters of the Walker river. The copper mines are in the low enclosing mountain ranges both to the east and west, with two of the largest and most promising mines but three or four miles southwest of the town. These two mines, the Bluestone and Mason Valley, are on the east flank of what is known as the Smith Valley range, which separates Mason valley from the parallel Smith valley. On the opposite side of the range from the Mason Valley mine, and facing on Smith valley, is the Nevada Douglas mine. These three are the proved mines of the district.

The railroad follows the west side of the Walker river, and at its closest point to the Mason Valley mine is the railroad town of Mason. This is the present terminus of car service and gives promise of rapid growth as soon as the railroad shops are built and the Mason Valley mine begins shipments. The railroad is being extended south to the head of the Mason valley, and from there it will pass into Smith valley and turn northward to the Nevada Douglas property, giving 26 miles of track where the air-line from Mason to the Nevada Douglas is but four miles. A low pass at the north end of Smith Valley leads into Mason valley, placing the Nevada Douglas within 17 miles of Wabuska by wagon-road. The grade is too steep for a standard-gauge railroad, while the present route of 40 miles to the mine passes near other mines, through both agricultural valleys, and taps tributary territory beyond. The present outside interest in the district after a lapse of three years is due to the construction of the railroad and the announcement of the immediate building of a smelter to handle 800 tons per day. This signifies that the surface prospects that attracted such marked attention in the days of 23-cent copper and were so quickly forgotten thereafter, have been steadily developed, and at depth now show a sufficient tonnage of sulphide ore to justify the large expenditure necessary to provide transportation and reduction facilities.



Yerington District. (After Ransome, U. S. Geol. Survey.)

The credit is to be given directly to two companies, the Mason Valley Mines Co. and the Nevada Douglas Copper Co. Both have been consistently developing their properties to a depth of 600 ft., and have wisely decided to work together in treating the ore. The Nevada Douglass people put in the railroad and the Mason Valley people built the smelter. Liberal contracts have been signed for the hauling of the Mason Valley ore over the railroad, and for the smelting of 200 tons of Nevada Douglas ore at the smelter. This working combination greatly strengthens the belief that the district will make good in the commercial production of copper. The personal credit for the energetic progress made is due to the general man-

agers, George E. Gunn, of the Mason Valley, and Walter C. Orem, of the Nevada Douglas, and to their consulting engineer, Llewellyn Humphreys, all of Salt Lake. The smelter is to be built on alkali desert land two miles northeast of Wabuska, where water is abundant, but where there is no vegetation for miles. Jules Lebarthe, of Trail, British Columbia, is the metallurgist in charge of the design and erection of the smelter. He has established offices in Salt Lake. The track is being laid to the smelter, and grading on the site will begin shortly.

The Yerington district first produced copper ores for the market in the early seventies, when the Mason valley farmers gladly hauled the ore to the sulphuric acid and blue-vitrol plants of Dayton for a small sum in ready cash. Following this came the ambitious installation of three or four small matting furnaces, the fuel being charcoal which was burned on the mountains several miles to the west. With the decadence of the Comstock the copper industry of Mason valley relapsed, and the present leading properties were re-located from time to time. In 1900, men from Butte attempted to work the Bluestone mine, installing a 150-ton blast-furnace. By 1905 all the valuable ground was re-located and companies formed to push development, Salt Lake men being in the majority. In the boom times of 1907 approximately 2000 tons of 20 to 30% ore was hauled out by the Nevada Douglas and Ludwig mines, and every worthless ridge in the district was exploited as a copper mine. The Ludwig mine was purchased by the Nevada Douglass Copper Co. for half a million, the Bluestone mine was examined by experts employed by F. A. Heinze, and the Gelders spent thousands in churn-drilling the copper-stained porphyry on the flat west of Yerington in the hopes of developing another Nevada Consolidated. A large amount of honest development was carried on that disclosed in several properties sufficient ore to warrant deeper development in the quiet years that have followed.

The Smith Valley range, in which the principal mines occur, rises above Mason valley to a height of 1000 to 1500 ft., at first in well rounded ridges, then in ridges with table-like tops due to a capping of basalt. The rock that forms the core of the range is a granodiorite, and flanking upon this core are schists and limestones that are irregular in their extent and relation to each other, and show heavy faulting and folding. In many places they show evidence of strong metamorphic action. The metamorphic action in the limestone is evident to the eye in riding over the range; for where the usual light-colored limestone has been altered on certain ridges to a rock having a very high epidote or garnet content, these ridges have a markedly darker and richer color. The Bluestone hill on the Bluestone property and Douglas hill on the Nevada Douglas property show this difference to a marked extent, and on Douglas hill the contrast is sharp enough to be a traceable line. The granodiorite is also termed monzonite, this term being in local favor because of the known association of copper minerals with monzonite in Bingham and Ely. However, in this district the monzonite is not impregnated over large areas with copper minerals, and it is not the ore-bearing formation except in a few of the minor properties where the wall-rock is full of distinct

Ludwig Mine of Nevada Douglas Copper Company.

fissures and has been mineralized with pyrite and chalcopyrite, but hardly sufficient to be of present commercial value. The orebodies that bid fair to be worked at a commercial profit lie in altered limestone with no apparent connection with the granodiorite. They are either in extensive metamorphosed zones like those of the Bluestone mine and Douglas Hill of the Nevada Douglas company; or they are in irregular vein deposits like those of the Mason Valley mine and the Ludwig mine of the Nevada Douglas company. In the garnetized zones of the Nevada Douglas and Bluestone properties the entire zone carries a small but persistent amount of chalcopyrite, but a network of fissures through parts of these areas give richer zones that form the large commercial orebodies. In both the vein deposits of the Mason Valley and Ludwig mines, garnetized limestone carrying copper minerals is present, but does not form the main orebodies. In the Mason Valley the main ore consists of a massive pyrite carrying chalcopyrite, and in the Ludwig mine the primary ore is quartz carrying chalcopyrite, pyrite, and calcite.

The Bluestone mine, three miles southwest of Yerington, was the first property in the district to be developed and the claims were patented in the eighties. At present the property is owned by J. R. DeLamar. The orebody has been developed to a depth of 300 ft. by adits, the lowest of these being a main haulageway 1200 ft. long. In the summer of 1907 a 35-drill electrically driven air-compressor was installed at the mouth of the lowest adit, and a 50-hp. hoist was purchased to prosecute work below that level. Many improvements were made about the property and a force of over thirty men employed. Since the financial depression of 1907 work in the mine has been discontinued. The systematic development in the past has blocked between one and a half and two million tons of copper ore averaging 2¾% copper and about 75c. in gold and silver. Included in the above tonnage is about two to three hundred thousand tons of direct smelting one, but the great tonnage is of the lower grade. This concentrating ore is an altered limestone carrying high epidote with garnet and chalcopyrite, and extends clear to the surface, there being very little oxidized ore. The orebody being over 200 ft. wide with no overburden, will probably be mined by means of an open pit or 'glory-hole' at a very low cost per ton.

The problem of the mine is the metallurgical treatment of the low-grade ore that cannot be smelted direct on account of the low copper content, or water concentrated on account of the heavy gangue minerals. C. A. Week, the superintendent, after several years of experimental work believes the economical method of treatment is by magnetic concentration after crushing to 8 mesh and giving a slight roast in a tower roaster. With crude oil as a fuel for roasting, and electric power at $5 per horse-power month for concentration and power purposes, the total roasting and concentration costs should be little in excess of those for water concentration. Experimental work has shown that with a concentration of 5 tons into 1, the concentrate will have the excellent smelting composition of: Cu, 12%; FeO, 16; CaO, 25; Al_2O_3, 10; SiO_2, 25; and S, 10. This concentrate carries over 90% of the original copper content of the ore. Since the experimental mill has a capacity of 100 tons per day, the same results should be attained in a large mill. The increased extraction by magnetic concentration should overbalance any extra cost over water concentration. The company can mine, transport, and mill the ore by gravity systems, and it can transport the concentrate to the railroad by a gravity tram approximately a mile long. If a favorable smelting contract can be made with the new smelter this mine may become a producer.

The Mason Valley mine, which lies a mile south of the Bluestone, is in an area having an interesting surface geology. The ore outcrops in a north and south direction on the east side of a limestone ridge, being entirely in limestone. To the north is a black shale formation with a small belt of the same shale approximately 100 ft. wide lying parallel and on the east side of the mineralized foot-wall country. A soft lime shale interposes between this shale belt and an outcrop of andesitic and rhyolitic tuffs. These tuffs being comparatively soft are eroded into steep crests and sharp valleys with many evidences of fantastic wind erosion. These rocks are evidently not intrusive. The surface ore is a fairly pure malachite, and the mine has a record of over 1000 tons shipped from surface pits with over 30% copper content. The mine was purchased in 1906 from Mr. Sprague, a rancher of Mason valley, by the Gunn-Thompson interests of Salt Lake. Consistent development has been carried on for over three years, opening the vein for a length of 1000 ft., and to a depth of over 500. This work has been through adits. No. 1, 300 ft. long, was driven by hand through garnetized limestone to the vein at a cost of $30 per foot. The vein at this depth, 100 ft., was dipping to the east and had changed to a heavy garnet pyrite ore carrying chalcopyrite. Adit No. 2 was started by hand work in the garnet lime to cut the vein at 200 ft. depth, but with the advent of electric power a 75 hp. compressor was installed at a lower point, from which point adit No. 3 was driven 1000 ft. to cut the vein at a depth of 350 ft. Over half the distance was driven through the garnet limestone. The work, done with piston drills, cost $15 per foot. The development on this level was carried on by driving in the garnet rock to the north and south, as, near the vein, it carries chalcopyrite, and is similar to the Nevada Douglas ore. After intersecting massive pyrite farther to the west and finding it to average over 4% in copper for 200 ft. along the vein and over 50 ft. wide, and finding also that although this ore blended gradually into the garnet limestone it ended sharply on the opposite side along a fissure with a barren limestone beyond, further development was carried on with the idea of cutting through the garnet rock to the fissure and following it with cross-cuts at frequent intervals back through the vein to the garnet limestone. This method gave a cheaper and more rapid development of the mine. The massive pyrite, with more or less chalcopyrite, was found to lie along the fissure in variable width, but at 500 ft. south of the first large orebody the vein widened and reached an average 3½% copper

content for a distance of 300 ft., until at the south end of the property it is sharply faulted. On this level the vein dips slightly to the west, which is opposite to the dip on the level above. Adit No. 4 was driven 2000 ft. to cut the vein at a depth of over 500. Most of this distance was through soft lime shale, and the adit was driven with piston drills at the rate of 150 ft. per month and a cost of $7 per foot. On this same material drifts have since been driven with small hammer-drills of the Waugh type at a cost of $3 per foot. Drifts on this level run directly under the north ore-shoot of the level above failed to intersect the ore, and this was the cause of adverse rumors. Raises intersected the ore and by driving south a distance of 180 ft. the orebody was found again, which shows this ore-shoot to have a steep pitch to the south. On development the ore proved to be equally as good as on the level above.

Stoping in Mason Valley Mine.

Development of this level from the first was carried on by driving to the south on the fissure and crosscutting the ore at an average of 50-ft. intervals. The south ore-shoot was found directly under its position on the third level, and was of equal magnitude. A winze sunk on the fissure at this orebody continues in ore and seems to show that the vein again dips to the west, which is favorable, since it carries it away from the black shale belt that had been approaching closer with depth, with a consequent narrowing of the garnet-lime zone.

The conception of the fissure vein and the development on the third level, leading to the more scientific development of the fourth level, has taken the property from the category of 'irregular bodies or ore in a replaced limestone' to a distinct vein deposit of pyrite and chalcopyrite, formed on the east side of a north and south fissure. The vein is of variable width, grading into a garnet-lime ore to the east, much of the latter being above a 2½% grade. The ore now counted on for direct smelting is in the large ore-shoots in the vein and contains over 3½% copper content. An estimate of the amount of this ore blocked is 600,000 tons.

At the present time the superintendent, J. J. Welch, has started a stope on the north ore-shoot on the third level and on the south ore-shoot on the fourth level for the purpose of determining the cost of extracting the ore, and to get a better idea of the average copper content. The method of stoping employed is to leave 12 ft. of ore in place above the level to protect the latter and to provide ore-pockets, and then after the first horizontal cut with piston-drills to mine by the shrinkage stope method, using small hammer-drills. The firmness of the ore and wall-rock makes possible this method of mining without timbering, and greatly reduces the cost. The stope on the third level is now 30 to 40 ft. wide and over 100 ft. long. The mining cost in this stope at present is given at less than 75c., and with active mining operations it is estimated at 60c. In the stope on the fourth level the mining cost is now $1 per ton, because of the greater amount of garnet gangue present. The car samples from these stopes have given ½ to ¾% higher copper content than the original sampling of the level and raises.

The company spent $180,000 last year in development, and with the present stopes opened along the length of the smelting ore the mine is fast rounding into shape to furnish its quota of 600 tons per day to the new smelter. The present question is the method of connecting the mine with the railroad, which is at a distance of 1¾ miles and with a drop of 600 ft. in elevation from the portal of adit No. 4. An aerial tramway can be used, but a survey is being made to see if it is possible to bring a railroad grade

far enough up the slope to allow direct loading into railroad cars from the portal of a lower adit to be over 4000 ft. in length and 200 ft. deeper on the vein. The latter plan looks beyond present outlay of capital to the future handling of the ore and possible mine-water below adit No. 4. Above this the mine is comparatively dry.

Although the surface ore is entirely oxidized and oxidized ore in small bodies is found even on the lowest levels, there is little secondary enrichment to chalcocite and cuprite, the oxidized ore passing almost directly into the solid pyrite and chalcopyrite ore, this latter being considered the primary ore.

The property of the Nevada Douglas Copper Co., consisting of over 30 claims, lies three miles to the west of the Mason Valley mine on the opposite flank of the range. It includes two groups of claims, the Nevada Douglas and the Ludwig. The main orebodies of the Nevada Douglas group lie in a garnetized limestone. The main orebody on Douglas hill shows a series of fissures, the strongest being a north and south series, which series is intersected by east and west and northeast-southwest series, the whole giving a network of fissuring. These fissures were simply channels along which the depositing solutions found there way into the adjacent limestone, giving irregular orebodies without definite walls, but often extensive in size. The higher grade ore occurs at the intersection of the fissures, and of this about 1500 tons was freighted out to the railroads in 1907. The composition of this shipping ore was 15% Cu, 0.01 oz. Au. 0.5 oz. Ag, with 23% SiO_2, and 20% FeO. This ore has a distinctive appearance of its own, being locally known as 'spot ore'. It is a mixture of small even-sized but irregular shaped grains of chalcocite, malaconite, bornite, chalcopyrite, pyrite, and garnet.

Development on Douglas hill was carried on by an adit at a hundred foot depth, with raises to the surface and winzes to an additional depth of 50 to 70 ft. This one garnetized zone extends over a large area, being roughly 600 ft. wide and 2500 ft. long. On the western end, 2000 ft. west of and 600 ft. below Douglas hill workings, is the Casting shaft, which is 80 ft. deep and has fair ore. A tunnel 600 ft. long was driven from near this shaft toward the upper workings, and with its raises, winzes, and cross-cuts adds a large tonnage of ore assaying better than 3½% in copper. The estimates of the tonnage developed on the Douglas group, due to the irregular shape of the orebodies, vary from 200,000 to 500,000 tons of better than 3½% copper ore which, mixed with Ludwig ores, can be smelted direct. Besides this tonnage of direct smelting ore there is a vast quantity of 1½ to 3% ore which, on account of the garnet gangue and partly oxidized condition, offers a difficult metallurgical problem. Two other garnetized zones on this group have been only slightly developed. The total amount of work on the group is about 7000 ft., which is but a meagre amount toward the possible development of the large mineralized areas.

An 18-drill Ingersoll-Rand compressor and a 100-hp. hoist were installed at the Casting shaft in 1907 with the intention of sinking 500 ft., but with the purchase of the Ludwig group, which had already attained a depth of 500 ft. from a point approximately on the same level, the deeper development was shifted.

The Ludwig group is of small area, but contains a vein that shows on the surface for hundreds of feet as an iron-stained gossan some 30 ft. wide. Oxidation extends to a depth of 500 ft., giving carbonate ores in a silicious iron-oxide and calcite gangue. Below this level the ore is quartz and calcite carrying sulphides. The vein has a north-south trend with a dip of 48° to the east. It occurs in limestone near the line of contact of a hard crystalline limestone on the west and a softer impure variety to the east. In the limestone to the west is a wide belt of hard pure gypsum. Dikes of altered porphyritic rock have been found on the extreme south drifts at the 500-ft. level that carry sufficient chalcopyrite to be ore of commercial grade. The width of the vein is considered to be 80 ft., but the walls are irregular and there are large and frequent horses of pure calcite. Below the 500-ft. level there is a sharp change to sulphides, and the 550-ft. level is in the zone of secondary enrichment. Here are found lenses of chalcocite and of cuprite carrying native copper. On the 650-ft. level there are still secondary ores on the footwall side, but it is believed that the remaining sulphide ore is near to being the primary sulphide ore. This vein furnishes a striking example of the copper vein as usually described in text-books, beginning at the surface in a gossan and becoming richer with depth in beautiful azurite and malachite ores, which in turn give way to heavy black chalcocite and red cuprite ores with green copper-water standing in pools, with copper-sulphate crystals coating the walls of poorly ventilated drifts, and below this a plain quartz sulphide ore with clear mine-water.

Up to the time of the purchase of the Ludwig group the mine had been worked with the idea of making profits on shipments of high-grade ore, with the result of expensive gophering without showing the possibilities of the property. To the 400-ft. level the mine was worked through a vertical single-compartment shaft in the hanging wall, and to the 550-ft. level by an incline sunk 200 ft. to the east of the shaft from the 400-ft. level. Heavy flows of copper-bearing waters had resulted in the installation of costly bronze-lined steam-pumps. The Nevada Douglas company put in a 2000-ft. line of 6-in. air-pipe from their compressor to the old boiler-plant for the hoists and air-drills, and pushed development on the 500 and 550-ft. levels, with sinking to the 650. By 1909 there were 1200 ft. of drifts on the 500-ft. level, 2000 on the 550, and 750 on the 650, giving an estimated reserve of 200,000 tons of direct-smelting ore above the 500-ft. level, and 325,000 of the same from the 650 to the 500. This was considered sufficient to justify plans for reduction works, and since that time the general manager has devoted himself to the building of the railroad, and the superintendent, Samuel S. Arentz, to putting the mine in shape to produce the necessary daily tonnage. The system of two small independent hoists had made development costs excessive. The underground incline has been extended through to the surface as a two-com-

partment shaft. This was done entirely by Waugh drills and without timbering, the broken rock being drawn just enough to give a free working face. The head-frame has been carried high enough to allow for ample ore-bins, from which the ore will be loaded direct into the ore-cars. Work will soon begin on an aerial tram from Douglas hill to the railroad below. The company plans to ship 200 tons per day of the various ores to give an average composition of 5.25% Cu, 24.6 FeO, 32 SiO_2, 7 to 10 CaO, and 3 to 6 Al_2O_3. Like the other ores of the district, there is no zinc, antimony, or other troublesome element in the ore.

At present the Yerington district is very quiet from a mining standpoint, the activity being concentrated on the railroad and smelter construction, but with these completed the district will become a steady copper producer.

JAPAN'S MINERAL OUTPUT

Official figures show an increase of from 6 to 20% compared with 1908 in the production of the chief minerals. The following is an official résumé of the production:

	Amount.	Value.
Gold	9,933 lb.	$2,483,300
Silver	341,360 lb.	2,258,795
Copper	1,146,130,496 lb.	11,494,770
Lead	8,577,053 lb.	223,807
Bismuth	992 lb.	754
Tin	47,568 lb.	11,979
Antimony	536,020 lb.	23,040
Quicksilver	1,352 lb.	549
Zinc	60,719,200 lb.	155,399
Pig Iron	118,011,499 lb.	826,080
Steel	15,697,541 lb.	211,417
Sulphide	72,176,150 lb.	68,567
Manganese (?)	17,619,019 lb.	28,190
Arsenic	17,702 lb.	461
Phosphorus	3,628,499 lb.	8,328
Graphite	757,498 lb.	13,828
Coal	14,973,617 tons	30,546,179
Peat	94,300 tons	82,591
Kerosene	41,675 gal.	3,184,962
Sulphur	94,621,040 lb.	366,625

KOREA'S MINERAL PRODUCTION

The following is the official report of the mining industry in Korea for 1909:

	Number men.	Number mines.	Area acres.
Gold	277	116	45,200
Silver	10	7	1,480
Copper	42	29	11,270
Mercury	2	2	340
Graphite	173	109	24,900
Coal	69	34	13,460
Zinc	5	3	1,370
Others	165	89	36,600

The total amount of gold obtained in Korea in 1908 and 1909 respectively was about $2,500,000 and $3,056,000 in value. The annual production of gold from the mines at Unsan is about $1,500,000 in value, according to the Seoul *Press*, and that of Synnan, which is worked by Soichiro Asaro, is $140,000, while the annual output of gold and alluvial gold taken from the mines at Chieksan amounts to $60,000 and $29,000 respectively.

Cananea Furnace Practice

By Courtenay De Kalb

The following notes deal with a number of the more vital details of practice, and represent the excellent character of the work being done at the great smelter of the Cananea Consolidated Copper Co. under the direction of L. D. Ricketts, the general manager. The plant in operation contains six blast-furnaces and one reverberatory. A second reverberatory is under construction, and will soon be in commission. The blast-furnaces are 48 by 210 in. at the tuyeres, and at the top they measure 5 ft. 2 in. by 7 ft. at the inner edge of the jackets, and 7 by 17 ft. inside the hopper at the feed-floor. In height they are 11 ft. 11 in. from the top of the base-plate to the inner edge of the jacket, and 13 ft. 6 in. from the top of the base-plate to the top of the hopper. On the base-plate are laid two courses of clay-brick, making a bottom-lining 10 in. thick. The water-jackets consist, for each furnace, of a total of 12 on the sides, 2 ft. 11. in. by 12 ft. 6¾ in., and two right-hand and two left-hand jackets on the ends, 9 ft. 7¼ in. high and 2 ft. 6 in. wide at the bottom by 3 ft. $1^1/_{16}$ in. wide at the top. All jackets have a 5-in. water-space, and are made of plates, ⅝-in. steel being used on the inside and ⅜-in. on the outside.

There are 36 tuyeres per furnace, three in each side-jacket, each tuyere having a diameter of 5 in. The total quantity of jacket-water circulated is 340 gal. per minute per furnace, which is at the rate of 1757 gal. per ton of wet gross charge. The water enters the jackets at a temperature of 70°F., and leaves at a temperature of 105. The capacity of each furnace is 280 tons of wet gross charge per diem, of which coke constitutes from 9 to 11%. The individual charges weigh approximately 2100 lb. each, and five such lots are charged to each furnace about every 30 minutes. The height of full smelting-column is 8 ft. 11 in., measured from the centre of the tuyeres. The furnace is carried full to the upper inner edge of the jackets. The labor required for the six furnaces is 1 foreman, 2 chargers per shift, and 1 feeder, 1 helper, and 1 coke-wheeler per furnace per shift. The air-pressure is maintained at an average of 16 oz., the average temperature of the blast-air being 64°F., with a mean humidity of about 31%. The temperature of the blast-air varies between the limits of 73 and 56°F. The dust-loss amounts to 8% of the gross wet charge.

The flues from the furnaces to the bottom-flue are 6 ft. diam. The balloon-flues are two 'goose-necks' 8 ft. 6 in. diam., and two balloon-flues 12 ft. 6 in. diam., with an area of 135 sq. ft. each, leading to the dust-chambers. The latter consists of a main and a stack-chamber, made of brick, covered by a roof of rails and concrete. The flues to the stack have brick walls and a sheet-steel roof. The dust is settled by retarding the velocity of the gases by means of an increasing area of dust-chamber. The main dust-chamber is 60 by 181 ft., by 32 ft. 6 in. high, the area for passage of gases being 970 sq. ft. The flue to the stack is 20 ft. wide by 19 ft. 6 in. high, and 242 ft. long, and the chamber at the base of the stack

is 84 by 34 ft. in horizontal section by 23 ft. 6 in. high. The stack is self-supporting, made of steel 19 ft. 9 in. inside diameter, lined with 9-in. common brick, leaving, net, an area for the passage of gases having a diameter of 18 ft. 3 in. The height to the top of the stack above the foundation is 168 ft. 3½ in., the foundation being 25 ft. above the level of the ground. The temperature of the gases at the bottom of the stack is 450° Fahrenheit.

The charge carries Fe 26.5%, Cu 6.39, and S 17.11, this being figured on the gross weight. The mixture is calculated to produce a bi-silicate slag, the average composition of which over a considerable period is:

	Per cent.
SiO_2	39.00
Al_2O_3	9.20
FeO	36.30
CaO	11.10
ZnO	1.50
MnO	0.53
MgO	0.48
Cu	0.40
S	0.70

The matte-fall, under the conditions obtaining in regular work, is about 18%. The matte has the general composition:

	Per cent.
Cu	37.4
Fe	34.8
S	26.1
SiO_2	0.5

Other bases, arsenic and antimony, are not determined. These are small in amount. No speiss is produced. The coke used assays:

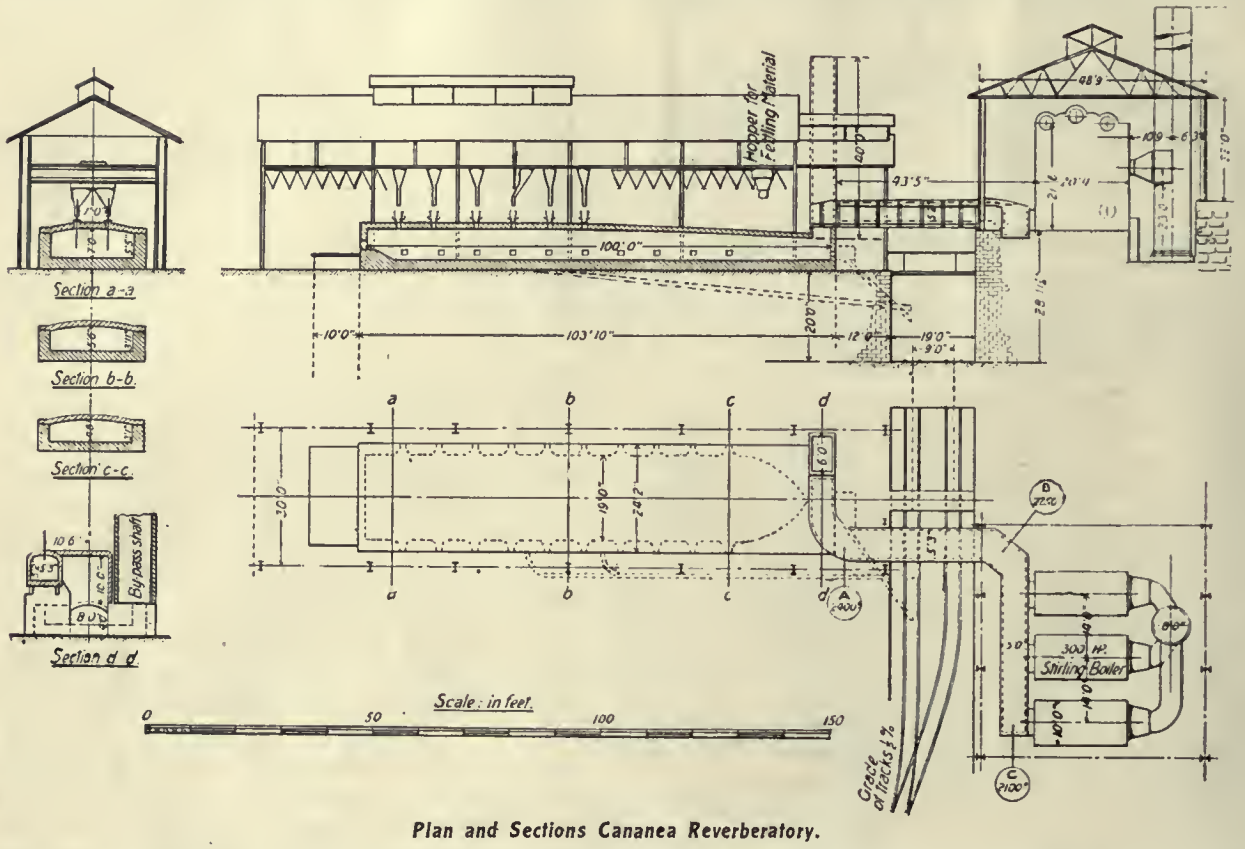
	Per cent.
Moisture	0.65
Fixed carbon	78.79
Volatile matter	2.02
Ash	18.40

The ash shows on analysis:

	Per cent.
SiO_2	53.5
Al_2O_3	23.2
Fe	11.4
CaO	4.6

The forehearths or settlers are made of steel plates ¾ in. thick on the sides and ¼ in. on the bottom. The forehearths are oval, 8 ft. 6 in. long by 4 ft. high, with a radius at the ends of 7 ft. The lining on the sides is of silicious converter-tamping for 12½ in., faced with 9 in. of chrome-brick. The bottom is of clay-brick, 10 in. thick, except under the furnace-spouts and at the tap-hole where the top-layer is made of chrome-brick for an area of about 9 sq. ft. The frequency of tapping from the settlers depends, of course, on the speed of the furnaces, and on the grade of the matte. When running about 280 tons of charge per furnace, making 30% matte, a tapping is made every hour. Each tapping draws off from 4 to 7 tons. During the period of 2½ years that these forehearths have been in service one lining has been re-built, and two linings out of the four settlers in commission, have been repaired. No repairs have been needed upon any of the shells to date. The furnaces are connected to the forehearths by copper water-jacketed spouts, having 2-in. water-spaces. The wear comes principally on the nose, which needs occasional patching. Four of these have needed repairs up to the present time. The furnaces have been in service two and a half years during which only slight repairs have been made to the jackets.

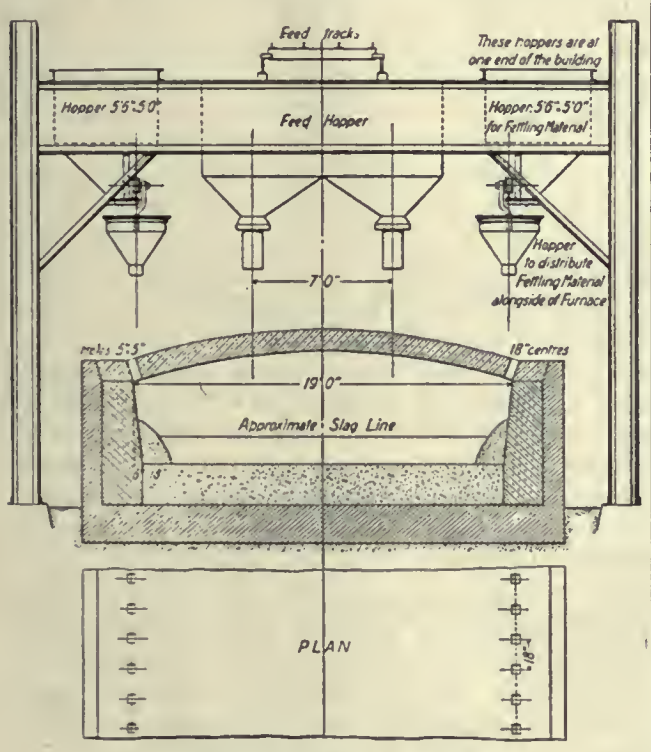
For the most part it is aimed to keep the tuyeres dark, but no trouble is experienced in keeping them bright. They are barred out at least three times per day, and punched every three hours. Wall accretions in the furnaces give no trouble. They are



Plan and Sections Cananea Reverberatory.

barred down at the beginning of each 8-hour shift, and oftener if necessary. When not pouring converter-slag into the settlers very few accretions form there. A gradual freezing of the ends farthest from the furnace-spouts occurs, however, because of defective circulation. There is also a tendency to thickening of the roof, which is easily remedied.

Corresponding to the six blast-furnaces are five stands of converters, the shells measuring 96 by 135 inches. The converters are blown through 14 east-iron tuyeres, 1½ in. inside diameter each. The blast-pressure is 12 lb. at the power-house, and the temperature of the blast-air is 64°F. The charge varies from 4 to 7 tons of matte, which is blown from 30 or 32 to 60% copper in from 40 to 60 minutes, this time including that consumed in pouring 'taps' from the settlers, skimming slag, and all operations about the converter except 'punching up' new shells, finishing the charge, and pouring the copper bullion. The



Cross-Section Cananea Reverberatory.

time depends on the size of the 'tap', condition of the converter, and other circumstances. Sufficient raw matte is then poured into the converter to make a proper finishing charge. Charges which will pour from 25 to 90 bars of bullion apiece will take from 20 to 40 minutes to finish. The total matte treated per diem by the battery of converters is about 217 tons; the consumption of lining 71.5 tons; and slags skimmed 95.8 tons. The converter slag after the first pour, from 60% matte, has the following composition:

	Year 1909, per cent.	April 1910, per cent.
SiO_2	26.8	21.5
Al_2O_3	6.2	7.4
FeO	58.3	60.9
CaO	1.5	1.2
S	0.8	1.1
Cu	2.44	2.50

The composition of the slag from the finished charge has not been determined. The matte is blown to blister assaying 99.1% copper.

A new lining for a converter-shell requires 10.3 tons of material. The ore used for this purpose, which comes from the mines of the company, has the following composition:

	Per cent.
Moisture (H_2O)	5.60
SiO_2	56.00
Al_2O_3	14.20
FeO	5.40
CaO	1.70
S	5.50
Cu	2.49

One lining will suffice for 24 tons of raw matte, or 8.9 tons of blister copper produced. Ten to thirteen shells are lined per day. These are dried by an oil-flame, 2.93 bbl. of Oklahoma crude-oil being required to dry out one converter-lining in about 10 hours. The matte ladles, of east steel, have a holding capacity of 68 cu. ft., and last about three years. The slag-cars have a capacity of 45 cu. ft., the bowls now in use having been in service for 2½ years. The converter-house is served by one 40-ton and one 50-ton crane, with 50-ft. span, requiring 13.6 hp. The converter gases are conducted through a 4-ft. flue to a stack 5 ft. diam. The total labor required per diem is as follows:

	Shifts. Number.	Hours.	Total men per day.
Blast-furnace charging floor..	3	8	72.6
Blast-furnace slag-floor	3	8	61.1
Converters, including cranes..	3	8	43.6
Lining gang	2	8	52.4
Clean-up gang	1	10	24.4
Bullion gang	1	10	6.2

The total air requirements, in terms of horse-power per ton of raw matte (30 to 32% Cu) produced and charged are: blast-furnaces, 0.0651 hp.; converter-blowing, 0.0728; converter-rotating, 0.00098; crane-work, 0.00207. The converters take 5230 cu. ft. of air per minute per converter, or 220,000 cu. ft. per ton of bullion produced.

The reverberatory practice at Cananea, which has included some of the most interesting metallurgic pioneering undertaken in America, was fully described by L. D. Ricketts in the Bulletin of the Institution of Mining & Metallurgy, November 28, 1909, under the caption 'Experiments in Reverberatory Practice at Cananea, Mexico'. The accompanying cuts show the furnace substantially as it is today, including dimensions. The notable circumstance in connection with Mr. Ricketts' work has been the adaptation of crude-oil as fuel. This has led to many economies in actual cost of fuel, in labor, and in repairs. The lines of the furnace, originally designed for burning coal-slack, have proved so nearly correct for oil-fuel that the only important change in the design for the new furnace, now being erected, consists in a greater elevation of the arch above the hearth-bottom in the 30 ft. of the rear of the furnace, that is, nearest the fire-box. The flame has a tendency to corrode the arch in the present furnace at that point. Four Shelby oil-burners are used, which enter the fire-box through ports in the rear wall. The fire-bridge remains as when coal was

employed. At the present time the average consumption of oil is 216 bbl. per diem. Taking the maximum and minimum for April 1910, the charge treated varied between 242 and 293 tons per day; the corresponding oil-consumption being 221 and 238 bbl., or 0.77 to 1.05 bbl. per ton of charge. The waste heat from the reverberatory generated steam in the Sterling boilers set in the flue-course in quantity sufficient to give a credit for fuel to the reverberatory varying from 0.33 to 0.48 bbl. of oil per ton of charge smelted. Thus the net consumption chargeable to smelting was only 0.43 to 0.57 bbl. per ton. The burners are operated under a steam-pressure of 125 lb. Other details concerning the economy of oil in reverberatory smelting can be found in the paper by Mr. Ricketts, cited above.

The number of charges per diem is about 20, all dumped through feed-hoppers in the arch toward the rear of the furnace. The charges are not spread, but are allowed to melt down and distribute themselves. The oil-flame is not shut off, nor dampers closed in the flues, while charging. The charge is made up of the following materials:

AVERAGE CHARGE FOR YEAR 1909.

	Per cent.
Flue-dust	70.87
Calcine	17.74
Flux	6.35
Fettling (raw ore)	5.03
Miscellaneous	0.01

The analyses of flue-dust and calcined concentrate are shown below:

	Flue-dust, per cent.	Calcine, per cent.
SiO_2	27.96	30.78
Al_2O_3	6.15	5.35
Fe	29.92	30.02
CaO	2.02	?
S	11.06	7.14
Cu	7.56	9.20

In the month of April just passed the percentage of flue-dust and calcine used were respectively 37.14 and 51.51, and the proportion of flux was 5.08%. The reverberatory slag has the following composition:

	Per cent.
SiO_2	38.8
Al_2O_3	10.0
FeO	37.9
CaO	7.6
S	0.8
ZnO	1.9
MnO	0.32
MgO	0.28
Cu	0.45

The reverberatory matte, which represents a matte-fall of 24.97%, gives the following results by analysis:

	Per cent.
Cu	32.0
Fe	35.9
S	28.9
SiO_2	0.46

One of the most interesting and unique features of the reverberatory practice here consists in fettling with green silicious ore, such as is used for converter-lining. This is crushed to a maximum of ½ in. diam., and is fed to the fettle-line through small ports in the arch just inside the side-wall lining. The ports are 5 by 5 in., and are spaced 18 in. apart. The fettling is dumped upon the arch and hoed into the holes, thus falling into place, and requiring no further labor to protect the lining from corrosion along the slag-line. When not fettling the ports are closed by tapered fire-clay plugs. In this way, an operation, which in ordinary practice constitutes part of the cost, becomes here an economical means of smelting a refractory copper ore. Material as coarse as ½ in. diam. cannot be fed in the charge successfully.

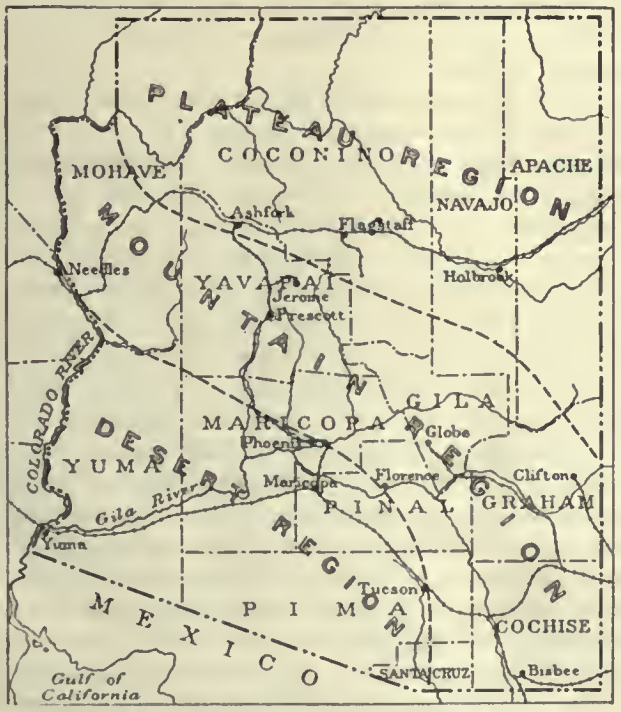
The preparation of flue-dust for blast-furnace smelting has been attempted many times by mixing the dust with refinery or with converter-slag. The success has not been complete, and the cost of handling has usually proved high. Mr. Ricketts has devised a simple system which has yielded an ideal product for the blast-furnace, and at a cost so low as to equal the advantages of treating flue-dust in the reverberatory. A shelf was excavated in the side of the slag-dump to give a foundation for a slag-car about 14 ft. below the upper track, and about the same height above a receiving-bin at the bottom. On the track-level above are provided a hopper for receiving flue-dust, and a hopper with a spout for conveying molten slag to the slag-car below. A spout also extends from the dust-hopper to a point over the centre of the slag-car such that when the slag is being poured, and forms a vortex in the molten mass in the bowl, the flue-dust will be discharged in the centre of this vortex, and be drawn down into the slag, thus becoming uniformly mixed with it. When the slag-bowl is full, it is dumped over the steep side of the slag-pile, down which it rolls as a viscous mass. It balls up as it tumbles downward, and forms so-called 'bombs', not unlike the balls of fritted cinder in a cement-kiln, except that they are of larger diameter, ranging from ½ to 12 in. The red-hot 'bombs' are sprayed with water from a hose, being quenched as coke is quenched on being drawn from the oven. The 'bombs' are of good tenacity, will bear handling exceedingly well without disintegration, and are porous and permeable to the blast. The converter-slag will take up about 20% of either flue-dust or raw concentrate. The FeS_2 present is largely reduced to FeS, thus facilitating the formation of matte, and adding to the speed of smelting.

German copper trade in 1909 showed some increase over 1908. It is stated that 194,449 metric tons (of 2,204.6 lb. each) of copper were consumed, about 5000 tons over 1908. About 90,000 tons were used for electrical installation, 38,000 for manufacturing plates, bars, and tubing, 41,000 for making brass, 2000 by chemical factories, and about 23,000 by shipyards, railroads, and for copper fittings and armatures. Germany produced 31,009 tons of copper, including that made from imported ore and scrap. The world's production of copper in 1909 is estimated at 834,940 English tons, in which the following countries were the principal participants: United States, 487,020; Mexico, 56,250; Spain and Portugal, 53,000; Japan, 45,000; Australia, 38,350; Chile, 35,800; Germany, 23,500 tons.

Stanley Butte District

By F. Wolf, Jr.

The formation in the Stanley Butte mining district, in Graham county, Arizona, 18 miles south of San Carlos by wagon-road, consists chiefly of granite and albite of the Archean system. On the granite lies conformably a belt of quartzite of the Upper and Lower Cambrian series. Paralleling and lying conformably on this is a belt of Carboniferous limestone. The sedimentary rocks all have a southeasterly dip of about 35°. The quartzite zone itself is some 400 ft. in thickness. The overlying Carboniferous limestone is more than 600 ft. thick. The entire zone is intersected by porphyry dikes, upon which and adjacent to, copper ores are found. These ores upon the surface are mostly carbonates and oxides, but at shallow depths, in places, sulphide ores have been exposed. There are, at the present time, two companies operating in the Stanley Butte district. The Copper Reef Con. Mines Co. is now driving an adit, which is in 370 ft. Development is being carried on rapidly, and the company is planning to increase the present force of 24 men. As soon as two 40-hp. hoists, already shipped from Lansing, Michigan, are received and installed, the sinking of two double-compartment shafts over 3000 ft. apart in the main lode, will be commenced. A long deep adit for drainage and easy handling of the ore is contemplated. Surveyors are at work preparing maps of the property. The original purchase was supposed to include 80 claims. Recent additions will increase the number to about 120. The Cobre Grande Co., holding a group of 14 claims, and under the management of A. F. S. Cooper, is working 12 men. An orebody, 30 ft. wide, has been recently developed at a depth of about 125 ft. This orebody is a sulphide, and averages 4% copper, though portions of the vein show a high percentage. At the present the Iron adit is being driven to tap the new orebody at a greater depth. The Yellow Metal group, which lies in the middle of the district, is under option to Eastern men. This group consists of some 65 claims, and has good surface showings of carbonate and oxide ores. The Starlight mine, a group of 12 patented claims, owned by the Tri-Bullion Co., of New York, is at present not on the active list. This mine was worked years ago by the early Spaniards, and contains gold, silver, copper, and lead ores. The Friend adit is in some 800 ft. This property is owned by Blake & Harvey. The Phoenix & Eastern railroad will probably resume construction work on its proposed route through the Box canyon of the Gila river, at an early date. Its present terminal is Winkleman, and it is the intention to connect with the Gila Valley, Globe & Northern at San Carlos, thus establishing a direct and shorter route through Arizona. The Territorial Board of Control has surveyed a wagon-road from Globe to Douglas, by way of San Carlos, Stanley, Klondyke, Wilcox, and the Sulphur Spring valley. Construction work upon this territorial high-way will shortly be commenced.



Globe in Relation to Physiographic Regions of Arizona.
(After Ransome, U. S. Geol. Survey.)

PERMISSIBLE EXPLOSIVES

Prior to 1909 little information was available to coal operators or State mine inspectors relative to the liability of explosives to ignite coal dust or coal gas, and thereby to cause explosions, except the information or supposed information contained in the claims made by manufacturers of a few so-called safety powders. Early in 1909 the United States Geological Survey undertook to test the explosives on the market. On May 15, 1909, the Geological Survey issued Explosives Circular No. 1, and on October 1, 1909, Explosives Circular No. 2, giving lists of permissible explosives. On May 16, 1910, a third list was issued, including all permissible explosives tested up to that date. This list shows that fourteen additional explosives have been placed in the permissible class since the issue of Circular No. 2. These are as follows:

Aetna coal powder D, Aetna Powder Co., Chicago, Illinois.

Coal special No. 3-B and coal special No. 3-C, Keystone Powder Co., Emporium, Pennsylvania.

Eureka No. 2-L. F., Tunnelite No. 6-L. F., and Tunnelite No. 8-L. F., G. R. McAbee Powder & Oil Co., Pittsburg, Pennsylvania.

Titanite No. 3 P, Waclark Titanite Explosive Co., Corry, Pennsylvania.

Trojan coal powder A, Trojan Powder Co., Allentown, Pennsylvania.

Detonite special, Detonite Co., Cincinnati, Ohio.

Monobel No. 2, Monobel No. 3, Carbonite No. 4, and Hecla No. 2, E. I. du Pont de Nemours Powder Co., Wilmington, Delaware.

Kanite A, W. H. Blumenstein Chemical Works, Pottsville, Pennsylvania.

The production of quicksilver in the United States in 1908, as obtained by the Geological Survey from returns from mines producing during that year was 19,752 flasks of 75 pounds each, valued at $824,146.

Well Drilling Machines for Copper Prospecting

By W. G. Weber

*The machines now in use in Arizona are of the traction type. Both Keystone and Star outfits are used. Drilling practice is practically the same in all cases, so the following description of Miami methods is applicable to all.

Before drilling can be commenced an adequate water supply must be provided, and this was not always easy in the Miami district. Water is pumped from wells, springs, or underground workings, through pipe-lines as much as three miles long, to tanks placed at the highest points on the ground to be drilled, and thence through temporary lines to the machines. Between an actual shortage of water in periods of drought and the freezing and bursting of these temporary lines in cold weather, much time may be lost.

The ground to be prospected is divided into 200-ft. squares, each corner being marked as a drill-hole location. Roads are then built to these locations, the road work being kept far enough in advance of the drills to avoid delays on this score. As the roads must be at least 9 ft. wide and substantially built, and as the surface of the ground prospected is almost invariably rough, these roads are quite an item of expense. Moreover, since they can seldom be used for any other purpose, they must usually be charged entirely to drilling. The roads should not exceed 15% in grade. A drilling machine can pull up a steeper grade, but the team of horses hauling the coal and supplies must be considered.

When a machine arrives at a location, it is blocked and leveled; the drive wheels are disconnected from the engine, and the spudding arm is attached to it. The mast is raised and steadied with wooden braces and with ⅝-in. steel guy ropes. A floor, 14 by 18 or 20 ft., built of 2-in. plank, is laid in front of the machine; in the summer a simple roof of corrugated iron is built over this floor, sides and ends of the same material being added in winter. A longitudinal opening about 3 ft. wide is left in the roof to allow the handling of casing and tools. Water tanks and a portable coal-box are also placed before drilling commences.

The string of tools for starting a hole, or 'spudding in', usually consists of a 10-in. bit, 4 in. by 20-ft. auger-stem, and rope-socket. The tools are strung up, a hole is cut in the floor where they will drop, and work commences. When spudding, the cable passes direct from the tools over the crown pulley, down to the spudding wheel, and thence to the drum where the excess cable is wound. This spudding line is generally a section cut from a worn drilling cable; 1⅞ to 2-in. manila cable is used. The spudding wheel is moved on an arm in such a way as alternately to raise and drop the tools in the hole. As the depth increases, cable is unwound from the drum, so that the tools may always strike a fair blow on the bottom. When about 5 ft. of progress has been made, the cable is thrown off the spudding wheel so that it passes direct from the crown pulley to the drum; it is then wound on the latter, pulling the tools out of the hole. A bailer is then lowered into the hole on $^{7}/_{16}$-in. steel line wound on a separate reel. The bailer is often made of casing pipe, 4 to 8 in. diam. and 10 to 20 ft. long. A dart valve on the bottom opens when the bottom of the hole is reached, thus admitting the sludge. The bailer is then hoisted to the surface and emptied into a trough which conducts the sludge to the sampling device. The bailer is run until the hole is dry, or all the cuttings have been removed. It is then swung back out of the way, the drilling tools are run back into the hole, and spudding is resumed. A varying amount of water is needed in the hole to keep the tools cool and to take up the sludge. When the natural flow is not sufficient, this water is thrown in from the surface.

With a Keystone machine, spudding may be continued to a depth of several hundred feet. With a Star machine, however, the wear and tear on machine and cable are too great, and consequently the Star driller 'hitches on' as soon as practicable, generally at a depth of from 100 to 125 ft. Then, instead of carrying the motion up over the crown pulley and back again, the rope is attached by clamps and a temper-screw to a beam extending out over the hole, and operated by a crank and pitman. That part of the cable above the clamps is not used while drilling is going on, but is pulled aside out of the way. In pulling out, the cable is unclamped, the pitman taken off the crank, and the beam is pulled up out of the way, and the cable is then wound on the drum just as when spudding. A pair of short-stroke jars is inserted in the string of drilling tools between the stem and the rope-socket.

A drilling crew consists of two men—a driller and a helper or 'tool dresser'. There are two crews to a machine, each working a 12-hour shift, changing at noon and at midnight. When moving or casing, both crews work in the daytime. Holes are drilled on the average to a depth of 500 ft. or until below the limits of commercial ore. The rate of drilling is quite variable, depending on the rock found, the depth, and the amount of water flowing into the hole. With a 10-in. bit in average dry rock, which stands up well, 40 or 50 ft. per shift is not uncommon. On the other hand, shattered and silicified schist which tends to cave and settle in the hole, and soft sandy schist and granite which tend to run in at the bottom, are often found in the Miami district, and in such material a drill may work a week or so and make little or no progress; in fact, the ground may come in faster than it can be drilled out. The presence of much water in a deep hole may also retard drilling, both by flotation of tools and cable, and by resisting the motion. In such cases it appears advisable to use a wire cable, with 100 to 150 ft. of manila cable, inserted immediately above the tools to absorb the shock and lessen the strain on the machine. The accompanying table shows in a general way the variations in the rate of progress with respect to depth of hole and nature of work.

It is evident that in shallow holes, the time re-

*Abstracted by *Engineering Contracting* from the *Wisconsin Engineer.*

quired for moving and setting up may become a prominent factor in determination of the average rate of progress. Under delays are included shutdowns, re-drilling bad holes, cleaning out after casing, and except in No. 2, time spent in fishing for tools lost in the hole. A drilling machine is expected to average 750 ft. a month, everything included. Delays in drilling may be due to various causes, as noted above, some of the chief of these being briefly explained here.

Crooked holes and flat holes sometimes interfere. Theoretically a drill-hole should always be vertical, round, and to gauge, but either through carelessness on the part of the driller or otherwise, variations from the ideal hole are many and troublesome. As a result the bit sticks or the tools lag and do not hit an effective blow. The common remedy is to fill the hole up above the bad place with fragments of quartz gathered on the surface, and then re-drill it. Sometimes a four-winged star is used in place of the

	Time (hours)						Depth of hole (ft.)	Depth of permanent water level (ft.)	Rock	Kind of drilling	Feet per 24 hr.

regular bit and extra wide rope sockets are also used to reduce the play of the upper end of the tools in the hole. Shooting the hole with dynamite is occasionally attempted with but rather indifferent success. In spite of all precautions few drill-holes are vertical or straight, the tendency being to deflect a foot or two in a hundred.

Cavings, or pieces of rock falling from the sides of a hole, may seriously delay drilling, as well as interfere with sampling. Large quantities of rock often fall suddenly on the tools and may wedge them in so tightly as to make is necessary to cut the cable, if indeed it does not break, and fish for them with a second string. Sands running in from below may produce the same effect. These cavings occasionally fill the hole as much as 50 ft. or even more above the bottom, and even if they do not catch the tools, much time is lost removing them. Usually casing the hole will stop the caving. Three sizes of casing are used in Miami, 7⅝, 6¼, and 4½ in. diam., weighing 8 to 13 lb. per foot. When a hole is cased, it is necessary to use smaller bits and tools. Four sizes of bits are used, 10, 7⅝, 6¼, and 4½ in., these figures representing the diameter when dressed to gauge. With the last named bits, a smaller string of tools, 3¼ in. diam., is used.

A hole may be cased several times if necessary. Each size of casing reaches to the top of the hole, and all are removed when the hole is finished. When casing is being handled, the drilling tools are lashed to the mast, and usually the manila cable is unwound from the drum, a wire cable being put on in its place. With this line, the joints of casing, each 18 to 20 ft. long, are hoisted over the hole one by one threaded together, and lowered until the bottom is reached, or until they will go no farther. The casing rarely needs to be driven, and then only with light blows, this being accomplished by stringing up the tools and dropping them gently on a block placed on the upper joint of the casing. To remove casing the process of lowering is reversed. When it does not pull readily, pulley blocks or hydraulic jacks or both are used, and occasionally dynamite is lowered into the hole and exploded to jar the ground loose. There are also a number of special tools, such as steel nipples, casing spears, and the like, used in special cases and better described in the makers' catalogues than is possible here.

Finally, a serious factor in delaying drilling is the fishing job. The cable or one of the tools may break, a joint may become unscrewed, or the tools may be wedged so tightly by sudden falls of ground or runs of sand, that the jars will not work, and the rope must be cut. Then the fishing job commences. Many and various tools are kept ready for emergencies, for it takes weeks to get anything from the supply houses. A fishing job is delightfully uncertain; it may last an hour or a week, or the hole may eventually have to be abandoned. In the last case, a new hole is usually started a few feet away. A second and a third string of tools may be lowered into a hole, to recover the ones already there, only to be lost in turn. Sometimes when success seems assured, some unexpected occurrence puts things in worse

shape than before. Thus in one hole, a bit broke off at the pin, and the driller lowered a horn socket gently, to feel for the part remaining and learn, if possible, how it lay. The horn socket is aptly described by its name, resembling a megaphone somewhat in shape, and in this case it slipped over the bit and took just enough friction hold to bring it along to the surface and then drop it back in the hole, where it remains yet, all further efforts to recover it proving unavailing.

The object of this drilling is, of course, to obtain information concerning the ground penetrated. For this purpose the sludge is bailed out at 5-ft. intervals, approximately the true depth being determined each time by measuring on the line. The sludge is dumped into a trough and conducted to a split divider which diverts one-eighth of the material into a tub. This amount may subsequently be reduced to $^1/_{16}$, $^1/_{32}$, $^1/_{64}$ if desired, by re-pouring the contents of the tub through the divider. The sludge is then dried over a fire, care being taken to prevent loss of sulphur through roasting; and the dried sample, which should weigh 25 or 30 lb., is sacked, tagged with the number of the hole and the depth at which it was obtained, and sent to the assay office. A sampler is employed on each shift to do this work. When two machines are working close together he can attend to both. He also takes a portion of each sample and pans it, noting the copper and iron minerals present, and their approximate abundance. The sulphides and oxides concentrate in the bottom of the pan; the copper carbonate and silicates are washed off, but may readily be detected even in minute quantities because of their bright colors. This and other information is recorded on a report blank.

The nature of the rock penetrated may be determined by the relative quantities of various minerals found in the sludge, and also by examination of such small unerushed fragments as are often bailed out. When the formation is not the same from top to bottom, and the hole is caving, the exact nature of the rock penetrated may be indeterminable. Faults and veins are quite readily detected in the capping over the ore through the presence of clay in the sample, also through marked variations in the amounts of iron oxides, copper carbonates, or quartz present in the sample. The width of the fault is represented by the distance through which this marked difference in mineralization occurs, but when the fault is steeply inclined, this is of course much greater than the true width. Faults in the sulphide zone are not so readily detected and doubtless are often overlooked.

A coal-dust burner using a jet of compressed air instead of a fan blast has been in successful operation for the past two years in a southern cement factory. Air at high pressure passes through a Koerting ejector nozzle and enters the kiln through a horizontal pipe. A vertical fuel supply pipe opens into the horizontal pipe just beyond the discharge end of the nozzle and between the nozzle and the kiln, the rapidly moving air jet carrying the coal dust into the furnace.

Less Known Gold Dredges in California

By W. M. Knox

Among the many successful dredges in California, outside of the well known Feather, Yuba, and American River districts, there are several isolated ones, of which little is known that are working with good results. The following notes, while incomplete, are representative.

On Scott river, Siskiyou county, a 7 ft., close-connected bucket, electric-driven dredge was operated until quite recently. The machinery was furnished by the Link-Belt Company, of Chicago. The boat has a capacity of about 60,000 yd. per month; its hull is 110 by 45 by 7 ft., and the stacker 94 ft. long. It was digging 33 ft., below water, in very tight gravel, and some boulders have been found that the buckets could not handle. The company generated its own electric power with two Pelton wheels of 350 hp. and has sufficient current not only for its boat, but a lighting plant also. The gold saving devices are of the Holmes type, and have an area of 960 sq. ft. A revolving screen with about 3600 sq. ft. of area is used. The water requirements for pond and boat are about 350 in., obtained from the river. The boat has already dredged about 25 acres out of a ranch of 500 acres which the company controls.

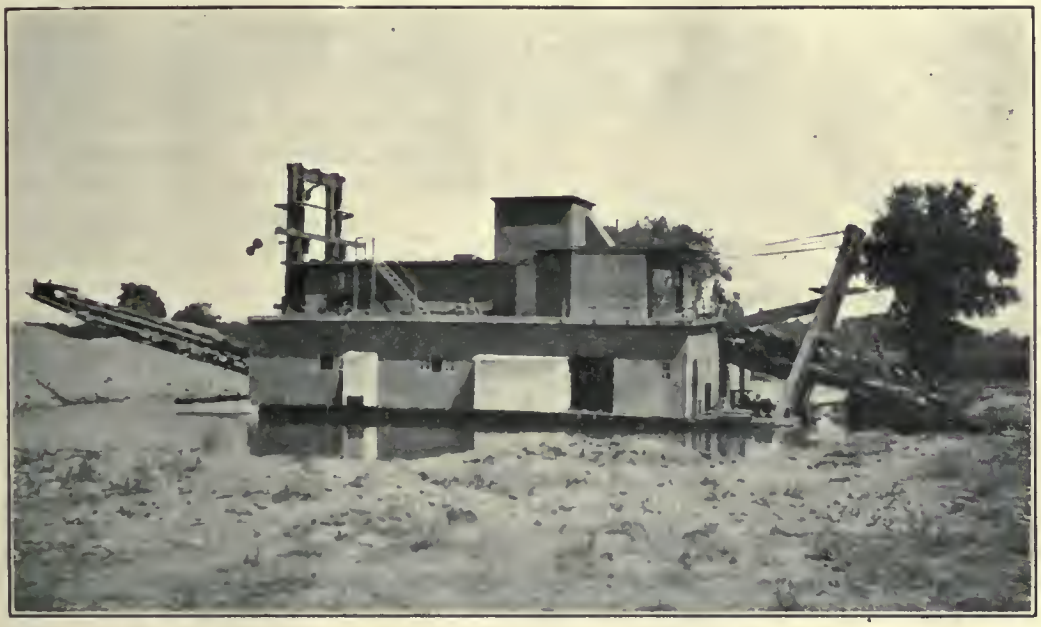
On McAdams creek, a tributary of Scott river, in Siskiyou county, is the Siskiyou No. 1, a 5-ft. boat, which is working in 40 ft. of loose gravel. It began operation this year. The dredge was constructed by the Yuba Construction Co., and is equipped with Bucyrus machinery.

In the Horsetown mining district, on Clear creek, Shasta county, the Shasta Dredging Co. is operating one 5-ft. close-connected bucket dredge, with a capacity of 50,000 cu. yd. per month. The hull is 95 by 40 by 8 ft., with a stacker of 90 ft. long. At present the boat is working in shallow ground 15 ft. below water and 3 ft. above. The creek gravel is very loose, but on the benches the gravel is compact and does not cave, though no powder is used. The power is electrical, and a total of 200 hp. is consumed by the different motors. The actual running time is about 80%. The gold saving devices have 1680 ft. of riffle surface obtained by placing part of the sluices outside of the housing, while the revolving screen is 6 ft. diameter by 30 ft. long. The water required is 50 miners' inches for pond and boat, and costs about $40 per month. The company controls 350 acres. The monthly costs per yard run from 2¾ to 6c.; the average would probably be about 5½c. Nine men are employed.

In the Mokelumne River mining district, on the Mokelumne river, near Wallace, is an electrically driven, 6-ft., close-connected-bucket dredge, built by the Mokelumne River Mining Co., which is working 70% of the total time. Its hull is 40 by 90 by 6 ft., with a stacker 80 ft. long. In December this boat was digging 25 ft. below and 4 ft. above water-level in fine well-washed gravel. Regular Holmes-type gold-saving tables are used, with machinery furnished by Allis-Chalmers Co. All water for pond and

boat is taken from the river by gravity flow. The company controls 195 acres, of which 145 acres remain to be dredged. The total cubic yardage for 1909 was 450,000. Twelve men are employed.

At Snelling, Merced county, on the Merced river, the Yosemite Dredging & Mining Co. is operating a 3½-ft. close-connected Bucyrus dredge. The hull is 40 by 70 by 6 ft., with a stacker 64 ft. long. The boat is working in loose river wash 15 to 21 ft. deep, no boulders, and works about 77% of the total time. The electric power consumed amounts to about 130 hp. and is generated at the railroad, two miles distant from the boat, by a distillate engine. Ordinary wooden gold-saving tables are used as gold saving devices. The water for washing and pond is taken from the river by gravity. The company controls 340 acres and has dredged to date 21 acres. About 3 oz. of platinum is saved monthly. It is of interest that this company can make its own power from distillate and run such a small boat.



Yosemite Dredge, on Merced River, Equipped With Bucyrus Machinery.

The Quinner machine, which is now attracting attention in Sonora, consists of a cylinder about 6 ft. long and 3 ft. diam., made of steel slats with interstices ⅛ in. wide. To a steel shaft passing through the cylinder are attached chains 3 in. apart and arranged in spiral form. At the free swinging ends of these chains are steel slugs 6 in. long and 3 in. diam., which clear the cylinder by about 3 in. The shaft revolves 375 times per minute, while the outside cylinder turns in the opposite direction 28. By centrifugal force the chains stretch out and the slugs strike a blow of 1800 lb. in one round. The spiral arrangement acts like a grinder and discharges the hard pebbles of the conglomerate from the end of the cylinder, while the cement which contains the gold grains is pulverized and passes through the interstices of the cylinder into troughs below. This powder is then treated by the ordinary dry-washer process. The pulverizer uses no water, and the only water required in the boiler of the engine.

Shasta Dredge on Clear Creek.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Pig-iron production in Canada during the fiscal year ended March 31, 1910, was 740,244 tons, and steel production was 740,390 tons.

Gold in granite country is common in California. Many of the granites in the Mother Lode districts contain gold-bearing veins in the granite, but the shoots in these are not usually extensive.

The tunnel on the Jungfrau mountain line is being driven at the rate of 10 to 12 ft. per day. The line is expected to be opened to an elevation of 11,090 ft. in the spring of 1912, and will eventually be carried to 13,670 ft., or only 242 ft. below the summit.

Rubber growing among the natives in Dutch Southeast Borneo is going ahead rapidly under official prompting. Government land has been granted to hundreds of natives for that purpose. In the district of Amuntai there are extensive plantations of Rambong rubber. Several planters, who have been buying there, have formulated a scheme for buying this rubber from the growers and for working it up on the spot. Native rubber growers have ordered large quantities of rubber seedling from Singapore.

A thunder-storm observatory has recently been established in Spain by G. J. de Guillen Garcia. By means of a wireless telegraph instrument the electromagnetic waves set up by lightning discharges are detected graphically and acoustically, the changes in the intensity and the distinctness of the sounds produced in the receiver giving the observer a clue as to the probable path of the storm and the rate of its movement. After a sufficient amount of data have been obtained it is hoped that forecasts of these storms will be made possible.

The average consumption of fuel per brake-horse-power hour in gas-producer tests made by the United States Geological Survey was 1.36 lb. of bituminous coal, or 1.99 of lignitic coal, the minimum consumption being 0.84 and 1.48 lb. respectively. Comparative tests of 75 bituminous coals under a water-tube boiler and in the gas producer showed that the average fuel consumption per brake-horse-power in the steam-plant was 2.7 times that in the producer plant. Several low-grade coals and lignites that were of little value, or even worthless, under the steam-boiler gave excellent results in the producer.

The Heroult electric furnace at the McKeesport plant of the Firth-Sterling Steel Co. has a capacity of two and one-half tons of charged material. The arc is formed between the electrodes and the bath of metal and the current which passes through one carbon, passes through the bath and out of the other carbon. These carbons project down vertically through water-cooled jackets on top of the furnace, which is lined with magnesite or dolomite. The Heroult furnace is nothing more than a modified open hearth, wherein the heat is applied above the metal by the electric current instead of gas. In order to maintain constant load a regulating device is used. This electrically operates two motors on the furnace whereby the carbons are raised or lowered. Power is obtained from three-phase mains and stepped down from 11,000 to 110 volts.

Wolframite is a tungstate of iron and manganese. It is the ore from which the metal tungsten is usually obtained. About one-fifth of the world's supply now comes from Argentina. One mining company, the Hansa Sociedad de Minas, produces six-sevenths of the entire Argentine output. It mines 60 to 100 tons of ore per month, ranging from 65 to 75% pure wolfram. The price of wolfram is about $1 a kilo (2.2 lb.) of pure metal. The amount of metal in a ton is estimated by the Government Chemical Assayer in Hamburg, Germany, where the ore is shipped. Prices are quoted there.

The life of a boiler generally depends upon the amount of corrosion to which it is subjected. With good feed-water which will neither corrode the metal nor cause a deposit of dangerous scale, and proper care to keep the surfaces of the metal clean, a life of forty years is not uncommon. With slow corrosion the life may be reduced to five years or even less, with the additional inconvenience that the pressure of steam which may be safely carried is continually being reduced. It is customary to analyze the feed-water if impure, and subject it to such chemical treatment as will render it fit for service.

The pollution of air in mines is sometimes due partly to the emanation of gases from the surrounding rocks, but principally from the following artificial causes: (1) respiration of persons and animals, (2) combustion of the candles and lamps, (3) absorption of the oxygen by pyrite and other minerals, (4) putrefaction of timber, (5) explosion of powder, and (6) dust from boring. Of these the decay of timber underground is one of the most important, and it should be urged that the practice of leaving the useless decaying timber to infect the new pieces put in, sometimes making a level a hotbed of putrescent matter, is both offensive to the senses, and injurious to the men.

Manganese ore is now being shipped from South Africa. The 5000 tons recently cleared for Antwerp, are stated to be part of an order for 150,000 tons, to be executed within the next two years. Already 13,000 tons more of manganese and about 7000 of iron ore are ready for shipment. Although the ore now being shipped to Antwerp contains phosphorus, and is therefore unmarketable in the United States, the company's officers believe that some of its mines, still undeveloped, will produce manganese without phosphorus. The mines are on a mountain a few miles from Cape Town, and the ore is dropped through chutes to carts, which convey it to the jetty, whence it is carried on barges to the ship.

Special Correspondence

BRITISH COLUMBIA

B. C. Copper Co. Takes Management of New Dominion.—Hedley Declares Dividend. — Important Discoveries on Portland Canal.—Vancouver Coal Items.— Ainsworth and Slocan.

It is officially announced that the British Columbia Copper Co. has taken the active management of the mines of the New Dominion Copper Co. Development has been started on the Rawhide property, and it is likely that shipments will be begun as soon as the two furnaces now undergoing enlargement at the Greenwood smelter are finished. The Brooklyn property of the same company is being unwatered, with a view to diamond-drill exploration in that ground. Harry Johns, superintendent of the Jackpot mine, will also have the superintendence of the new work in this vicinity. The first annual meeting of the New Dominion Copper Co. was held in New York June 6. A report covering the fiscal year ended March 31 showed $307,502 on hand. The sum of $30,371 was carried forward into the new year. Paul S. Couldrey, who for nearly a year has been superintendent of the B. C. Copper Co. Mother Lode mine, Greenwood, has gone to Peru. Mr. Couldrey has been succeeded by E. Hibbert, who formerly occupied a similar position with the Le Roi No. 2, Ltd., at Rossland. The Hedley Gold Mining Co., which controls the Nickle Plate mine at Hedley, has declared dividend No. 3 to the amount of 3%. This company began paying dividends in August last, and since that time has paid approximately $90,000 in profit-sharing to the stockholders.

At Rossland the Jumbo mine was examined during the past week by O. F. Riebel, expert for Finch & Campbell, of Spokane. A couple of thousand tons of gold-bearing ore has been shipped from this property and nearly $150,000 expended in development. There is between four and five thousand feet of work done in the mine. It is anticipated that Mr. Riebel's report on the property will be such as to warrant the resumption of work. It is expected that work will take a more active turn now at the Yankee Girl mine at Ymir, as H. L. Rodgers, manager, has returned from New York, it is rumored with plans for working on a larger scale. Gen. Molineaux and his son, principal stockholders, are making an inspection of the mine.

A large body of free-milling gold-bearing rock has been located near Stewart, on Portland Canal. The find is in the vicinity of Bitter Creek and the lode is stated to have been traced for twenty miles. It is 30 to 100 ft. wide and assays return an average of $6 over five claims. The find has excited the large number of prospectors in and around Stewart, and many are rushing to stake claims on the lode, which can be traced with the eye over the mountain ranges. There is talk of erecting a smelter at Goose Bay, on Portland Canal.

The Western Canada Investment Co. has enlarged its holdings in Graham island coal section from six to sixteen, thus covering 21 square miles of ground. The output of the Dunsmuir collieries is to be augmented to two million tons per annum.

In Ainsworth division, a Scottish syndicate has let a contract for driving a tunnel 300 ft. on the Swede group, Poplar creek. A new French company, the Emissions Minieres, Ltd., is putting a Pelton 5-ft. water-wheel and a Fraser & Chalmers 16 by 18-in. belt-driven air-compressor on the Joker group, at the head of south fork of Kaslo creek, and will drive a tunnel 800 ft. The Selkirk Mining Co. is repairing its flume, preparatory to resuming mining and concentrating at its Cork mine and mill, which produce silver-lead, but cannot yet make a marketable product of the zinc ore. The Flint and Bismark are also being worked. The Government is making a trail to the Utica, five miles from the railway, on which nine buildings are being erected. On the Whitewater group, new ground is being explored for other shoots of ore in the Whitewater Deep, and the raise from the lowest level—that of the Deep Mine, Ltd.—is being made 150 ft. before cross-cutting for the vein. The Whitewater mill has been started; meanwhile silver-lead and silver-zinc concentrates on hand are being shipped. Slocan mines promise increased tonnage. The Rambler-Cariboo has shoots of good silver-lead ore on both the 800 and 900-ft. levels, and the 1000-ft. is also being driven to cut these. The mill is again at work concentrating ore in the dump left near the mouth of the old shaft several years ago. Results of explorations at and below the 800-ft. level are justifying the expenditure incurred in driving a long tunnel at the 1450-ft. level. Nine men are working on the Washington. The Payne is to be examined by Mosco Vici, of Montreal, Quebec, for the Sandon Mine syndicate, which has a lease and option on the Payne mine and mill. The Ruth-Hope mill will concentrate ore from the Ruth, and turn out two products, namely, silver-lead and silver-zinc concentrates. The Hope has good shipping ore exposed ready for stoping; a new adit is to be started on the vein at 200 ft. vertically below No. 4. The Slocan Star is driving on its Slocan King and Hidden Treasure claims, cutting several ore-shoots and making raises to give ventilation before opening stopes. These drifts are to be extended into the Consolidated M. & S. Co.'s Eureka and Summit claims lying behind the Slocan Star group. A baby tram is being

Mineral Resources of British Columbia.

erected from the portal of one of these adits 500 ft. to the upper terminal of the Consolidated company's aerial tramway from the Richmond-Eureka mine down to the railway in Sandon.

Near Cody, on the Noble Five, development is going forward; in the Surprise a raise in ore is being carried from the 1100-ft. level toward the old workings 800 ft. above, and No. 8 adit is being driven to cut the Sunset-Trade Dollar vein at 500 ft. in on the Sunset Silver-Lead & Zinc Mines Co.'s group. In the Slocan Lake district, on Four-Mile creek, there is a fine showing of shipping ore in two drift faces on the Standard, 4 to 5 ft. of solid galena with fahlerz containing considerable silver; one vein has widened to 30 ft., mostly of concentrating ore, containing silver-lead and zinc in quartz. Both the Van Roi and Hewitt-Lorna Doone groups, in the same camp, are also looking well. About 100 men are regularly employed on the Van Roi, which has milled approximately 26,000 tons of ore during eight months ended May 31. Some 1200 tons of silver-zinc concentrate accumulated during last winter is being shipped to Oklahoma; silver-lead concentrate goes to Trail, British Columbia. A few men are working on the Fisher Maiden, Neepawa, and Ottawa. The Ellis Silver Mining Co. is employing 25 men on the Westmont, on Ten-Mile creek, which is developing satisfactorily.

GOLDFIELD, NEVADA

Goldfield Consolidated Mill Repaired. — Plans for Open-Cut Work.—Combination Fraction.—Florence Goldfield.—Leases Around the District.

Rapid progress has been made in repairing the damaged mill of the Consolidated Mines Co., and before the end of June the plant will again be operating at its former capacity of 860 tons per day. Shipments of high-grade ore will be then suspended. The output for June will approximately equal that of May, and the expense columns of the next monthly report will contain an item for construction completely wiping out the fire loss. All of the shafts are to be equipped with electrically driven hoisting machinery. The original Laguna shaft, which is being sunk by the Consolidated to the 700-ft. level, has progressed over 100 ft., and for a considerable distance has been in vein matter the greater part of which has been sent to the mill for treatment. This shaft will greatly facilitate the development of the Red Top at depth. Owing to the flat dip of the vein it is not likely that the Red Top shaft will be sunk to greater depth than the present 330-ft. level. Plans are now being carried out to mine the entire Combination vein from the lower levels to the surface, creating a gigantic 'glory hole' several hundred feet long. It is designed to mine later the Red Top vein in a similar manner from the 330-ft. level to the surface. The discovery made last month at a point about midway between the Red Top and Mohawk shafts, near the Gold Wedge fraction, is proving to be one

The Florence Mill.

of great importance. The ore was first opened on the 450-ft. level from the Mohawk and will be readily reached by driving from the 600 and 750-ft. levels from the Clermont. Another orebody that promises to be one of the company's best assets is that exposed on the 600-ft. level in the northwest drift from the Clermont and in the Red Top vein, on the Lucky Boy claim. The principal tonnage continues to come from the Mohawk mine, in which a large amount of development has been done and where a large tonnage of high-grade ore has been blocked, though production is confined to the ore of milling grade.

The Combination Fraction Co. is now operating the 20-stamp Nevada Goldfield mill, a mile north of town, and is treating from 75 to 80 tons of ore per day, the average of the product being about $25 per ton. Suit has been filed by the John S. Cook bank against the Nevada Goldfield Reduction Co. to foreclose a mortgage on the plant leased to the Combination Fraction company, the sum involved being $52,844. The mill, which was built by an association of Paris bankers, has a complete laboratory equipment and a sampler capable of handling 300 tons of ore per day. The orebody opened on the 50-ft. level of the Fraction is being developed on two other horizons with a highly encouraging showing on the 750-ft. level. It is in the main Mohawk vein and distinct from that first exposed on the 285-ft. level, and now being developed on the 300-ft. level.

The Florence Goldfield maintains a daily production of 150 tons, chiefly from the southern workings in the territory formerly embraced in the Little-Florence and Rogers leases. The main drift to the north on the seventh or 350-ft. level has reached a point below the workings of the bonanza Reilly lease and this territory, undeveloped below a depth of 260 ft., promises to supply a large tonnage of rich ore. Many leases are being operated throughout the district, some making frequent shipments. On the Atlanta, seven leases are working at depths varying from 250 to 730 ft. The best showing is at the latter depth on the Precious Metals Co. lease on the Black Bear claim. Three lessees are working on the Diamondfield Black Butte and two of these are saving ore of shipping grade. From the original St. Ives workings of the Merger Mines company the Ford lease is sending out high-grade ore and a shipment assaying $200 per ton was sent out recently from a lease on the Kendall. The Lind lease on the Booth has exposed pay-ore which apparently extends to the Goldfield Oro ground. The Weber-McLaughlin lease on the south end of the Booth is sinking another lift and will drive to the Red Top vein for the ore-shoot, the apex of which is thought to have been cut on the 150-ft. level. The Annex shaft, on the Polverde claim of the Jumbo Extension, is being sunk from the 800 to the 1100-ft. level, the ore having pinched at the former depth. The Codd Mines Co.'s lease shaft on the St. Ives claim will be sunk from the 550 to a depth of 1200 ft. or more. A 52-hp. electric-hoist has been installed on this ground and a contract let for further sinking. Lessees operating on the Goldfield Daisy have been making occasional small shipments and some good ore is being taken from the Goldfield Belmont. Driving is in progress from the Grizzly Bear shaft on the Consolidated in quest of the Mohawk vein. The Nevada Eagle, three miles west of town, has exposed ore of shipping grade.

TORONTO, CANADA

Cobalt Output. — Dividends Increase. — Gowganda and Porcupine Wait for Transportation. — High-Grader Convicted. — Lead Output Increases.—Mining Law Changes in Quebec.

The output of Cobalt mines for the first five months of 1910 shows a slight decline in tonnage as compared with last year's production during the same period, the figures being respectively 11,995 and 12,064 tons, but the value is considerably greater, owing to the larger proportion shipped in the form of concentrate. Whereas in the earlier part of last season only six concentrators were in operation, the number has now increased to thirteen, and several others will probably be installed before the end of the year. Among the companies which contemplate the erection of concentrating mills are the Crown Reserve and Hudson Bay, and others have contracted for the treatment of their milling ore by the Northern Customs concentrator. The five months' showing is therefore regarded as a satisfactory one. Three mines which appeared on the shipping list of last year have so far been unrepresented this season—Silver Queen, Nancy Helen, and Nova Scotia—but there are about ten new shippers, most of whose consignments, however, have been of an intermittent character. Several of the companies have declared extra dividends. The Nipissing, in addition to the regular quarterly 5% dividend and 2½% bonus, is giving an extra interim dividend of 5%. The McKinley-Darragh has declared the usual 3% quarterly dividend supplemented for the first time by a 2% bonus. The Buffalo adds to its regular 3% dividend an extra 5%. These tangible evidences of prosperity, while they have slightly increased the prices of the stocks affected, have had no effect whatever on the general market, which continues depressed, the long anticipated upward movement having even disappeared from the broker's advertisements. An important find has been made on the portion of the Nipissing property known as R. L. 406, being a rich 3-in. vein in Keewatin formation. This part of the ground has hitherto been considered of little value, and the discovery gives encouragement as to the possibilities of the remainder of the property. The La Rose is meeting with success in the trenching of the Fisher-Eplett location, having struck one good vein showing silver content for 250 ft. in addition to a number of promising stringers. The British American

mine has resumed operations, having recently put in a compressor plant. Five shafts have been opened and a contact let to sink the main shaft to a depth of 200 ft. The Beaver shaft is being put down to the 300-ft. level and ore is being stoped at the 200-ft. level. A car of high-grade ore, shipped last month, will net the company about $45,000. A vein was recently discovered in trenching at the Ophir from 6 to 15 in. wide of smaltite carrying native silver. A winze started on a vein in the north cross-cut will be put down to the 300-ft. level. At the Provincial mine, now being operated by a syndicate, a high-grade vein which had dipped from the shaft has been recovered in driving at a depth of 100 ft. It shows a width of over 3 in. and will average upward of 2000 oz. per ton.

The lack of transportation facilities is considerably retarding operations at Gowganda, rendering it unprofitable to ship ore of as low a grade as 400 oz. per ton. Consequently several of the companies are making no attempt at shipment, but are accumulating ore on the dumps to await the time when either transportation is improved or cheap power for concentration can be obtained. Among the mines which are taking out high-grade ore and will shortly make further shipments are the Millerett, the Reeves-Dobie, and the Bonsall. The Morrison property, where some wide and rich veins are in evidence, is under option to an English syndicate, which will soon begin operations. In the Porcupine gold camp the same difficulty as regards transportation prevails, and it is found impossible to get in heavy freight except during the winter. Consequently some of the smaller companies have been obliged to suspend operations. Development on the more important claims is making good progress. The Timmons Brothers are putting in a test-plant of 15 tons capacity to treat ore taken out in development work by amalgamation and cyaniding. The Hollinger plant is in operation with a force of 90 men. Assays of $347 per ton have been obtained from ore extracted at the 100-ft. level. The Miller company has extracted ore from the big vein assaying as high as $238 per ton. The camp has been visited by many prospective buyers and capitalists interested in mining, but the tendency of holders of undeveloped claims to ask prices which are considered exorbitant deters many investors from buying.

A recent act of the Canadian Parliament makes it possible to convict and punish the frequent offence of high-grading, by making it punishable to be found in possession of ore without being able satisfactorily to account for it. The first conviction under this provision was made about two weeks ago, when a foreigner arrested at New Liskeard, near Cobalt, with 14 pounds of ore from the Nova Scotia mine in his possession was given a term of six months imprisonment. An increase in the output of Canadian lead mines is indicated by the returns of the amount paid in bounties for lead ore delivered at Canadian smelters during the fiscal year ended March 31. The bounties at the rate of $15 per ton amounted to $340,542, representing 45,467,545 lb. of lead ore, as compared with $307,432 on 42,533,287 for the previous year. The reported finds of bituminous coal along the Metagami river in northern Ontario have been investigated by W. J. Bauldry, an expert engaged by the Temiskaming & Northern Ontario Railway Commission. He reports that no coal has been found, and that although lignite occurs, the known quantity is not large, and its value altogether problematical. There are, he states, large deposits of iron ore in the district which will yield 50% iron. Some important amendments have been made in the mining laws of Quebec province. The ownership of deposits of building stone, clay, peat, ochre, sand, and some non-metallic substances hitherto retained by the Crown in granting patents is vested in the owner of the surface. Money paid for mining licenses, which were practically leases, at one dollar per year per acre will be allowed on the purchase money when mining lands are bought. The time allowed between the date of staking a claim and the taking out of a mining license is extended from four to six months. The law exempting mines and plants from local taxation has been changed so as to exempt only the mine and the underground plant, the surface plant, mills, and buildings being made taxable.

ALPINE, TEXAS

Activity on Rio Grande Border. —Lasca. — Chisos.—Dalberg.—Llano District.—Quitman Mountains.

There is more mining activity in the districts of the upper Rio Grande border region at this time than ever before. Since, however, the Texas mining law restricts rather than encourages the prospecting and exploitation of claims situated upon public lands, practically all of the work now being carried on is upon private lands. An unusual number of prospecting parties are now in the mountains west and south of Alpine, and encouraging reports have reached here of promising mineral discoveries in different localities. Regular shipments of copper sulphides are being made from the Little Lightning copper mine, situated near Lasca, a station on the Southern Pacific railroad west of Alpine. This mine is owned by John Gilcrease who is at Lasca giving his personal attention to the development of the property. A syndicate of Toyah, Texas, men are developing a gold claim on Gomez peak, in the Davis mountains, eight miles southwest of Kent. The shaft is now down about 85 ft., and is said to be in ore all the way. Rich gold float

A Bit of the Desert.

has been found in that section of the Davis mountains from time to time. The Chisos Mining Co., of which Howard E. Perry, of Chicago, is the chief stockholder, is making important improvements to its Chisos quicksilver mine in the Terlingua district. It will soon have installed an electric hoist, an elevator for loading the ore, and an ice plant for the benefit of the camp. This company has been doing a profitable business ever since the mine was opened several years ago. Its furnace is in steady operation and regular shipments of flasks of quicksilver are made. The Texas Mica Co., which owns a mica mine near Dalberg station on the Southern Pacific railroad, is installing a large amount of machinery preparatory to inaugurating extensive development. The company owns two sections of land upon which the mica is found, and it is claimed that a large output is available. The Texas turquois mine, owned by A. D. Hudson and situated in El Paso county, continues to produce turquois of excellent quality. Mr. Hudson utilizes the output in his lapidary at El Paso. Joheph Lister, an experienced prospector, recently located claims in the Guadalupe mountains, north of Van Horn station on the Texas & Pacific railroad. He had a number of specimens of gold and silver ore assayed and with good results. The re-

cent revival of mineral development work in the Llano district is attracting the interest of mining men. It is reported that the shaft in the gold-silver mine, 12 miles south of Llano, owned by F. M. Ramsey, of Lampasas, Texas, and associates, is in good ore and that the prospect is favorable for shipments. It is planned to sink this shaft to a depth of 700 ft. It is already down more than 200 ft. The mining of rare minerals at Barrenger Hill, near Kingsland, has been going on successfully for several years. It is said to be one of the most wonderful storehouses of rare minerals in this country. Regular shipments are made to different parts of the country where the minerals are put to various uses. The Sierra Blanca Mining Co., which is developing mines in the Quitman mountains near Sierra Blanca, will build a wagon-road from the railroad station of Ettelyne to its mines, a distance of four miles. This company has uncovered large bodies of copper ore containing gold and silver. The Lulu B group of mines, owned by T. V. McKinney and William Crosby, situated in the Quitman mountains, are being developed into good producers of high-grade carbonate of lead ores. It is reported that regular shipments from the Tama mine to the smelter at El Paso will soon be started. This mine is also situated in the Quitman mountains.

SALT LAKE, UTAH

Lead Production Increasing.—State Inspector of Mines. — Dividends. — Utah Copper Production. — Bingham & Garfield Railway.—Wall Mill.—Daly-Judge.—Zinc Shipments.

Statistics for the year 1909 show that Utah ranks third in the production of lead, following Missouri and Idaho. Utah and Missouri show an increase over 1908, while Idaho shows a decrease. The output of Idaho is about 30,000 tons more than that of Utah, but has been declining during the past several years, while Utah's increase from 1908 to 1909 was over 20,000 tons. At this rate Utah will pass Idaho and take second place within the next two years. The matter of a State inspector for the metal mines is being agitated, with the prospect that a bill to that effect will be pushed in the next legislature. The proposition is to appoint an official who will have jurisdiction over both the metal and coal mines, the latter being the only ones that are under State supervision at present.

For the first six months of the current year various Utah companies have declared dividends to the amount of $4,382,552, as against $7,103,642 for the entire year 1909. Silver King Coalition has passed its second quarterly dividend and Utah Con. has not paid any so far this year. With the completion of several costly improvements at the Silver King, and the operation of the new smelter contract for the Utah Con., these companies should return to the dividend-paying class before the close of the year, which from present indications will be far better than last. Utah Copper heads the list with a total of over $2,300,000 for the first six months. The production of the Utah Copper Co. for the month of May was slightly in excess of 8,500,000 lb. of copper at a cost of about 8c. per pound. The net profits for the month were $400,000. The production for April was 8,000,000 lb., so the two months almost equal the record for the first quarter, which was 18,511,819 lb. at a cost of 8.43c. The directors of the Bingham & Garfield Railway Co. have authorized the issue of $2,500,000 in 6% gold bonds for the construction of the railroad from the mines at Bingham to the Utah Copper mills at Garfield. The railroad was decided upon because the contract with the Denver & Rio Grande railroad calls for the transportation of a maximum of 6000 tons of ore per day and the mills when remodeled will handle 18,000 tons. As the service under the old contract was far from satisfactory it was decided that the only thing to do was to build the railroad and operate it for the Utah Copper Co. exclusively. The bonds will be exchangeable for Utah Copper stock at $50 per share for three years after July 1, 1910, and the company can call them in at any interest day after three years by paying 110 and accrued interest. The Bingham Copper Co., which has passed through many financial troubles, has been practically reorganized and the announcement is made that it has been financed so that the development necessary to put it on a producing basis can be carried on. A new cross-cut from the main tunnel which was started last month has progressed at the rate of four feet per shift, and is now in low-grade ore, the first of three beds that are known to lie in that direction. W. D. Bohm, manager of the North Utah, has taken charge of the Bingham Copper Co. The Wall mill property of E. A. Wall, has been remodeled and will be started up on the ores of the Starless. The mill is unique, being equipped almost entirely with machinery of Mr. Wall's design. The ore is crushed in rolls in which the one roll is above the other, and is treated in washers instead of the usual tables and vanners. The Utah Apex is shipping 175 tons of ore per day to its mill and is producing about 45 tons of concentrate which will run 42% lead, 10 oz. silver, and 10% copper. While it is generally supposed that the company has a considerable amount of copper ore in its territory, no attempt is being made to develop it under present conditions, especially as it has prospects of becoming a really great lead mine. Stockholders of the Ohio Copper Co. are somewhat worried over the rumor that they may be called upon to give the company some financial assistance in order that the equipping of the mill at Lark may be completed. It hardly seems that such a move should be necessary. Although the tryout of the mill showed that there were some changes necessary, it has done good work and has made money while only running at one-half the ultimate capacity.

The Daly-Judge has been working a Starrett air-lift pump on the lower levels for some time and as it has proved successful, it is believed that it will be used to unwater the mine to the 1600-ft. level where operations were checked some years ago by a great inrush of water. The conditions on that level have been the cause for much speculation for some years, and development in that direction will be watched with interest. Work has been commenced on the Bonneville tunnel southeast of Provo, which will be driven by the Jesse Knight interests to prospect the mountains between Provo and Springville for mineral and water. The boiler plant at the Chief Consolidated at Tintic was damaged by fire, the roof being burned off. This gave rise to a report that the hoisting works had been burned. The damage was slight and caused only an hour and a half delay. The last two cars the company shipped netted $10,000. Ore of good quality is now being opened on the 1400-ft. level. The annual meeting of the Columbus Consolidated showed a slight contest for the management, but the old office holders won. Duncan MacVichie was elected a director, and while a great deal of the stock is held in Michigan, no Michigan man was elected to the board, although such has been the custom in the past. A raise has penetrated high-grade ore, so fine as to resemble a concentrate. The location of the raise was such that a great deal of the ore got into the water and was pumped out. The raise has been bulkheaded and another driven from which the ore is to be caught by driving. The Cedar Talisman has received returns on a carload of zinc shipped to Oklahoma which assayed 45% and netted $2335 after all expenses were paid. A second car assaying 44% has been shipped. The Moscow earned $13,000 during the month of May and wiped out the last of its indebtedness. A dividend of 50c. per share has been declared by the American Zinc Co., whose books show:

	1909.	1908.
Net earnings	$360,378	$85,145
Administration and general expense	58,583	20,452
Interest	57,351	47,265
Miscellaneous gains and losses	.....	15,364
Total deductions	115,934	83,081
Net profits	$244,444	$2,064

Three men were killed and fifteen overcome with gas by the explosion of a box of powder on the 1900-ft. level of the Opex mine on the morning of June 25. Two of the dead were killed outright and one by falling down a chute. At the last report all the others had been removed from the mine, but six are still unconscious. All of the men were Austrians.

BUTTE, MONTANA

North Butte.—Anaconda Output.—Elm Orlu.—Conrey Placer.—Butte & Superior.—Tuolumne.—Original.—Davis-Daly.

The dividend of the North Butte company, even though cut to 30c., seems to give an assurance to the holders of the stock that the management has great hopes for the future. Development is active and it is stated that the work on the 2000 and 2200-ft. levels of the veins of the Edith May and Jessie is showing excellent results. All the mines of the Anaconda company, and by this statement, all the properties of the Amalgamated company are included, are working up to their full capacity with the exception of the Parrot which has been down for several months and the Rarus. The output for June is expected to be fully up to that of May.

The report filed with the county assessor by the Elm Orlu Mining Co. shows that the net proceeds for the year were $20,164, which is considered a good showing. The Elm Orlu, a Clark property, is yet in its infancy as a zinc producer. The reports show that the number of tons extracted were 55,996, with a yield per ton of $10.34. The gross proceeds were $579,438 and the total expenditures $559,274. The cost of extraction was $4.25 per ton; transportation per ton, $2.54; reduction, $2.50 per ton, and construction expenses, $34,085. The Conrey placer, at the mouth of the famous Alder gulch, is said to be paying its owners big dividends. There are two dredges at work and in the course of the next three months a third, the largest in the world, will be started. One of the principal owners in this property is Harvard University and it is said that in the past three years the university has received in the vicinity of $1,000,000 from the property. The demand for Butte & Superior stock does not seem to have improved under the terms announced for the re-organization. At the present time the stock is going down, due to Duluth holders throwing it on the market. The circular letter sent out to the stockholders calling a meeting at Duluth for July 9, to consider the re-organization plans, gives in detail the scheme proposed and which has already been outlined. The plans as proposed by the directors meet with general favor in this city, where the mine is known to possess much valuable ore. The Washoe Copper Co. became the property of the Anaconda company under the terms of the merger on March 31, according to the deed filed with the clerk and recorder in this city. The document was executed in New York on May 31, and it is stated that the deed became effective on March 31.

Holders of Tuolumne stock were disappointed when it was decided to pass the expected dividend. The report of the secretary-treasurer showed a cash balance on May 31, of $308,146 as compared with $91,403 one year ago. The net proceeds of the company for the year were $112,619. There were 19,484 tons of ore extracted during the year with a value of $19.75 per ton and a total gross yield of $384,622. It was thought better to wait for a time before declaring a dividend as the price of copper is low and development can be carried on to advantage so that when the copper market advances there will be plenty of ore to treat and dividends can be declared and made permanent. The report states that considerable money has been expended in ascertaining just where the company stands with reference to the disputed ground, with the result that it has been clearly established that the veins claimed belong to the Tuolumne. Whether the North Butte management is satisfied as to the truth of this statement is not known, but it is known that up to a few weeks ago engineers of the Anaconda company were frequently in the Tuolumne mine examining the ground being worked and taking measurements.

The Original group of mines, formerly owned by the Clark interests, but on June 1 transferred to the Anaconda Copper Mining Co., at a price said to be in the vicinity of $12,000,000, shows net proceeds of $181,359 according to the report made to the county assessor for the year. There were 226,492 tons of ore extracted and the gross yield per ton was $8.10. The cost of reduction was $688,492. There was paid for transportation, $48,763; for labor, $547,751, and supplies, $368,219. The total gross yield was $1,834,585. The $1 assessment ordered by the Davis-Daly company will realize $600,000, while the mining expert who was sent out here in the interests of Boston people, declares that it will take $1,000,000 to put the mine in good shape. However, it is announced by the management that with the money received from the assessment it is hoped to proceed with development, to construct transportation facilities, and to realize on the ore reserves without being forced to borrow. Just how matters will work out is problematical. The Colorado mine has been shut down for some months and the owners have the question of the transportation facilities tied up in the Supreme Court. Should the decision of the court be favorable, the construction of a spur from the mine to the Great Northern railway track can proceed, but should the decision be unfavorable the Davis-Daly management will have to resort to some other means than the construction of the spur to get the ore to the Basin smelter, as the property owners along the proposed spur line are very determined and it is a question if the expenditure of a very large sum of money would induce them to relinquish their opposition.

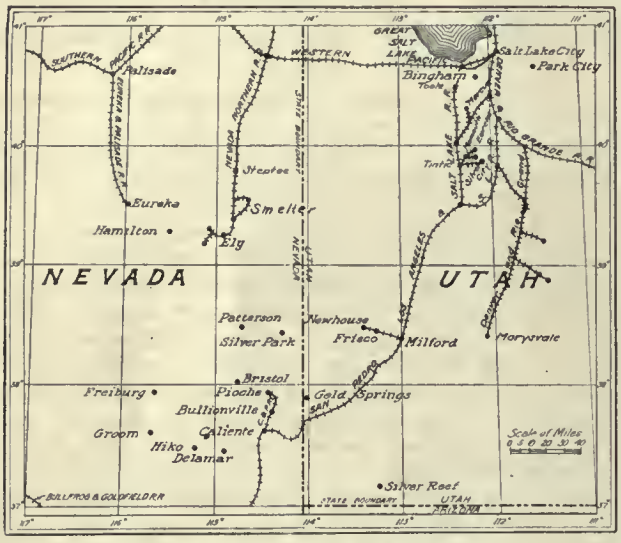
ELY, NEVADA

Steptoe Smelter Changes.—New Sampler. — Blackhorse Bonded. —Cortez Dump Sold.—Boston Ely to Drill.—Giroux Busy.

In efficiency of construction, and in ability to concentrate the ores, the Steptoe Valley S. & M. Co. mill holds a unique position. Unlike most new plants which fall far short in actual operation of the capacity claimed for them, the Steptoe is now treating double the amount of ore claimed for it when the plans were originally drawn. It was expected when the plans were drawn that each unit would handle an average of 1000 tons per day, but they are now actually handling more than double that amount. This is due to a variety of causes. First, the buildings were double-decked with concentrating tables, and, second, other capacities were increased, and it was also found that the ore concentrated much better than originally expected. While the concentrators are operating under ideal conditions, the smelting end of the plant has had difficulties to contend with, as the ores carry an excess of silica. This could be largely overcome by direct smelting ores, but unfortunately the Nevada Con. has not developed any. The ores from the Alpha shaft of the Giroux company would relieve the situation if shipped to the smelter. But these, it is unofficially announced, will be shipped to the International at Tooele, Utah, commencing some time during the fall or winter months. Two sets of Allis-Chalmers Style A high-grade rolls have recently been installed in the crushing department at the Steptoe plant. The rolls are placed underneath the coarse crusher and reduce the 3-in. product of the crusher to a size of 1½ in. In connection with the new rolls, a second inclined belt-conveyor has been put in which assists the one already in use to deliver the crushed product to the elevator supplying the mill bins. George F. Waddell, superintendent of the Steptoe concentrator of which the crushing plant forms a part, estimates that the new conveyor will increase the capacity of the crushing plant from 15 to 20%. The new rolls will have no direct influence on the capacity but will materially lighten the work on the rolls inside the mill of which there are three sets, one each of coarse, medium, and fine, to each of the eight sections. The concentrator is at present handling from 8000 to 9000 tons of ore per day. Concentrate is being put into storage in considerable quantities as the four reverberatory furnaces at present in operation cannot handle the output of the mill. Furnace No. 4 must soon be shut down for re-lining which will take about ten days and will put the smelter still further behind. It is believed that the Steptoe company must soon give orders for the completion of the fifth furnace, work on which was suspended early last winter after the furnace was more than half completed. The company is installing an 8-in. pipe-line about 8000 ft. in length in order to conduct the waters of Berry creek to the company's main reservoir on Duck creek, about six miles from the smelter. In spite of Nevada's reputation as a desert country, the smelter company has never lacked water. The present season, however, is unusually dry and

the management is making every effort to conserve the flow of Duck creek and its tributaries in order to insure a sufficient supply of water to last during the hot months of July and August when evaporation is at its greatest and the mountain streams are correspondingly low. A sampler for the testing of the mill tailing is being erected on the hillside west of the concentrator. Tailing from the mill has heretofore been carried off to the valley by three different sets of launders. As soon as the new plant is completed, all the tailing will be directed into one channel and be accurately sampled. Recovery at the Steptoe mill is from 71 to 76%, and the building of the new sampler is the first step in an attempt toward improvement.

The Blackhorse group, owned by Tommy Watkins, has been bonded to Salt Lake and Denver capitalists. Fabulously rich ore, some of it running as high as $100,000 per ton, was found on the Blackhorse mine four and a half years ago, and this naturally created much excitement and a rush. Thomas O'Neill, of Ely, secured a bond on the Blackhorse mine, paying down $10,000. Later he spent a considerable amount in development, but allowed his payments to lapse, and the property passed back to the original



Eastern Nevada and Western Utah.

locator, who has since been treating the ore in an arrastre with good results. The present bond was secured on the property by R. Courtright, of Blackhorse, and A. G. Burrett, of Salt Lake, who will at once put a force of men on development. They announce their intention to put a milling plant on the property within the present year. The Nevada Amalgamated Mining Company, owning the San Pedro group in the same district, is now engaged in the erection of a 10-stamp mill at San Pedro, about two miles from the mines. The work of construction has been delayed somewhat by the difficulty of securing heavy timbers, but they have at last arrived and the plant is being crowded to completion. The mill will also treat custom ores. S. F. Snyder, a mining engineer, has just returned to Ely from a visit to the old Cortez district in Eureka county, in which the new and live camp of Buckhorn is situated. The Cortez mine in former days produced $19,000. Its tailing dump has been sold for $30,000, and will be treated by the cyanide process. The Buckhorn mines are owned by George Wingfield, of Goldfield, and are being opened up for extensive production. Representatives of the United States S. R. & M. Co. are examining the property, with a view to purchase, it is said, for $3,000,000. It is further stated that if the smelting company secures the property, it will build a railroad from the Southern Pacific to the new camp. The Boston-Ely contemplates prospecting its ground from the 1227-ft. level with core-drills. The work above that level demonstrates a large area of leached material, containing copper carbonate, suggesting that an enriched zone will be found at greater depth. The Giroux Consolidated Co. is rushing the equipment of its 5-compartment shaft, which is said to be the largest in the State. The sump on the 1200-ft. level has been cemented and the pumping station is being completed. When this is done, one 1200 and two 600-gal. pumps will be installed, after which a cross-cut will be driven 700 ft. back under the old Alpha workings, where large bodies of high-grade, direct-smelting ores have been blocked. When this has been done it is expected the company will commence shipping to the new International smelter, and it is also expected that at that time the company will start its 500-ton concentrating plant, which has been idle for the past two years.

NEW YORK

Market Conditions. — Copper. — Porcupine. — Heinze and his Troubles.—San Cayetano.—Ray Central.—Greene-Cananea.

This has been 'old home' week for New York. Mr. Roosevelt returned amid a din of plaudits. Five or six days later another sojourner abroad came up New York bay, Mr. J. P. Morgan. He is home from several months spent in London, Paris, and in Italy, and is expected to restore the exhausted courage of the bulls. The semi-panicky hysterical condition of mind following the recent move of the Federal authorities against the Western railroads has worn off, but on the other hand there has been no return of that confidence which begets absorption, or even that which induces speculation. The convertible bonds of the various copper companies have already made for themselves a place among investors solely because of profit possibilities through conversion into stock, and unquestionably the dividend payers such as Goldfield Con., Nipissing, Kerr Lake, and others, are coming into greater favor through the pressure of higher cost of living which is compelling small investors of capital to seek larger returns. Amalgamated's 2% dividend, which cannot be increased, is compared disparagingly with the recent extra distributions made by Nipissing, and with the 60% paid by the Crown Reserve, and with the income derived from Camp Bird, Esperanza, El Oro Mining & Railway, and Mexico Mines of El Oro. Goldfield Con. has been accepted by the listing committee of the New York Stock Exchange.

The copper situation remains unchanged. The necessity for organization is becoming more apparent. Copper dividends are beginning to suffer somewhat. North Butte reduced its quarterly distribution to 30c. per share as against 50c. paid quarterly during the past year or more. North Butte's neighbor, Tuolumne, failed to meet expectations and, instead of declaring a dividend, voted to retain its surplus of over $300,000 in the treasury. The directors are evidently fortifying themselves against any possible break in the metal which might compel them to place part or all of their output in storage for a few months rather than sell in a market demoralized by desperate competition. Recently the abnormal and increasing production has been recognized as the critical point in the copper metal market and the consensus of opinion now is that consumption cannot be expected to overtake the present increasing output. The increase in surplus of 36,000,000 lb. in two months is sufficient to cause the consumer to buy only when purchases can no longer be postponed. Plans to add other large producers to the list are not being sidetracked and this is an additional feature which will compel the formation of a copper trust. Miami, Ray Con., and Ray Central are building mills. Chino is to be an open-cast property and steam-shovels are to be stripping the overburden as soon as they can be placed in operation, probably within 30 days. Drill work is claimed to have developed 18,000,000 tons of ore; the additional output from these mines will certainly force some radical action for the protection of the metal market. The South Utah Mines & Smelters Co., a re-organization of the Newhouse Mines & Smelters Co., has made a contract with the International S. & R. Co. for the handling of its ores and production from the South Utah will begin as soon as the new smelter at Tooele is prepared to handle the output. Application has been made to list the shares of the Shattuck-Arizona on the Boston Stock Exchange. In connection with the application it appears that the property is producing in round numbers 2,000,000 lb. of copper per month at a cost of 5½c. The Shattuck-Arizona adjoins the

Copper Queen and the Calumet & Arizona at Bisbee, and, in addition to the distinction of producing what is probably the cheapest copper in the United States at the present time, also holds a unique record in that it has 'paid its board' from the beginning of operations. There has been expended in development some $1,800,000, but of this amount the shareholders have contributed but $40,000, the balance having all been derived from the operation of the mine. At the present time the company is shipping about 160 tons of ore daily to the Copper Queen smelter and is earning $140,000 to $150,000 per month on the output, the ore running between 17 and 18% copper. There is some talk of opposition to the merging of the Mines Company of America, Dolores, and El Rayo, but it is not taken seriously.

The Porcupine situation remains unsettled. 'Spotty and uncertain' seems to be the verdict up to the present moment. Surface showings are admittedly wonderful, but those who have had previous experience with gold finds in Ontario are going very slowly. A recent visitor to the district says: "The country is muskeg from end to the other. There are no roads, so there is great difficulty in getting about. Considerable interest regarding the district was aroused by the finding of rich surface ores, and this was recently stimulated by the shipment of a carload of what was stated to have been an average of the ore from the Timmins shaft, which gave a return of $202.75 per ton. In my opinion, the excitement is unwarranted. The showings are not so phenomenal as we had been led to believe. The district is filled with men who are mostly unfamiliar with mining of any kind, much less gold mining. There is practically no one at all in the camp who has ever had any previous experience with gold mining with the result that the reports of finding free gold on the surface has been much over-rated. The carload that was shipped from the Timmins shaft was taken from three places, the major part coming from No. 2 shaft, which is now closed. It is stated that they have 15 or 16 veins on that property. The probabilities are that the workings in depth will prove unremunerative, the deepest shaft at the present time being about 70 ft. On the Wilson property, which is controlled by the Monell Nickel people, five shafts are being sunk 100 ft. deep, and it is proposed to connect them at that depth in order to prove the property. There is a phenomenal gold showing on the surface in places and the property is under option at a large price. There is a considerable amount of work going on in the camp but it seems to me that the expenditure of capital for development in most cases is entirely unwarranted by the surface showing. Prices asked are inordinately high, the experience of Cobalt being taken as a precedent despite the fact that conditions are entirely different." While this is admittedly based on a short visit it comes from a well known and competent engineer.

Miami Looking Southeast, April, 1910. Pinal Mountains in the Background.

It is beginning to appear that, in spite of all the jauntiness of F. Augustus Heinze during his recent grapple with the Federal authorities, his defence has cost him something of a pretty penny. Almost all his companies are in difficulties. The complete financing of Ohio Copper has been announced several times, but Mr. Heinze has just departed for Europe with the avowed purpose of placing some Ohio Copper bonds while abroad. Amsterdam interests hold considerable United Copper and are expected to help put some value in United by helping Ohio, a controlling interest in Ohio being one of the chief assets of United. If the Dutch bankers refuse to subscribe for Ohio bonds, the stockholders may expect to get an 'Irish dividend'. The holders of Davis-Daly have again been required to come to their own rescue by meeting an assessment of $1 per share, Silver King Coalition is badly involved in litigation, and, all in all, therefore, Mr. Heinze came forth from the court room only to confront a sea of troubles, for once not altogether of his own making.

The operations of the San Cayetano at Guanajuato are to be broadened and the company is to be an even more important factor in the camp than heretofore indicated. The recent increase in the capital stock of the company from $250,000 to $1,500,000, par $5, was evidently in preparation for increased activity as a holding and development company. The first step in this direction has just been consumated by the acquirement on the part of the San Cayetano Mines Co. of a large territory lying immediately to the north of the San Cayetano tunnel, the group of claims including La Joya, the San Juan de la Montana, El Puerticito, the Pabellon, the San Francisco de la Fortuna, and the Santa Virginia. Included in the deal was the completion of the title of the Meximora, in which the Guanajuato Reduction & Mines Co. has, up to the present time, had as undivided interest, the property having for a long time been included in the San Cayetano ground, under a leasing arrangement which is now discontinued and the title completed in the San Cayetano company. The newly acquired territory outside of the Meximora, which is one of the famous mines of the camp, is ground adjacent to the San Cayetano and from the work in the San Julian cross-cut of the San Cayetano is expected to prove of much value to the company. Adolph Lewisohn is in Europe, and in his absence his associates refused to discuss the future plans for the San Cayetano, though it is certain that the property is to be developed into one of the most important producers of the camp. There is a rumor of a merger of two of the Lewisohn properties in Arizona, or rather an absorption of one by the other. The New Keystone may be taken over by the Miami on the basis of five shares of New Keystone for one share of Miami.

The Ray Central Copper Co. is placing orders for the first unit of its mill. The equipment now planned is in the nature of an experimental mill of 1000 tons daily capacity, which if successful is to serve as the first unit of a larger mill to be immediately erected. The total of developed and probable ores of the Ray Central are now estimated at 15,000,000 tons. The management of the property is in the hands of J. Parke Channing. An analysis of the annual report of the Greene Consolidated Copper Co. reveals the fact that Mr. Greene carried his picturesqueness into his financial operations most consistently. He became a copper magnate on copper that cost him 17c. per pound to produce and even at that he insisted upon taking the best of the ore out of the ground. His Sierra Madre Land & Lumber Co., a 51% interest in which was carried on the Greene Consolidated Co. books at par $7,650,000, represented an outlay of only $650,000. The entire amount of this item has, under the new regime, been charged off and in addition some $4,205,966 has been spent in betterment and replacements the entire plant having been overhauled and largely rebuilt. Beside the amount mentioned, such work as could be legitimately charged to copper cost has been so charged, though it might more properly have gone to construction account.

The new Bureau of Mines will start out on July 1 with appropriations aggregating at least half a million dollars. The total amount granted in the Sundry Civil bill is $488,000. The principal item is $310,000 for the investigation of the causes of mine disasters and the establishment of nine additional so-called rescue stations.

General Mining News

ARIZONA

COCHISE COUNTY

The Wolverine & Arizona Copper Co., at Bisbee, is shipping about 250 tons of ore per month which is reported to be the richest now being handled in the district.——The Great Western Copper Co., at Courtland, has received the churn-drill that was shipped recently and will commence prospecting at once.——The shaft on the Leadville claim at Paradise is now over 140 ft. deep, the vein in the bottom being 20 in. wide. It is the intention of the company to continue sinking to the 220-ft. level and commence stoping ore for shipment. An average value of the ore, which consists of lead, silver, and zinc, is about $62 per ton.——The drift at the Commanche Chief is in 100 ft., having followed the vein for 80 ft. of that distance.——The shaft of the Red Mountain Development Co. passed through 15 ft. of ore at a depth of 100 ft. that assayed $10 per ton.

GILA COUNTY

(Special Correspondence).—The west winze sunk from the fourth level of the Gardner workings at the Superior & Boston mine is 127 ft. deep, and has been continuously in ore averaging 8% copper on the Black Oxide vein.——The cross-cut driven southward on the 500-ft. level of the Telfair shaft at the Arizona-Michigan property is 1000 ft. long and less than 100 ft. more of driving should open the Old Dominion vein. The formation in the face consists chiefly of shale, stained with hematite.——The total advance made in 30 drifts and raises at the Miami property during the week ending June 18, was 1000 ft. Exploration and blocking out of a tip of the orebody running west on the St. Johns claim has developed 440,000 tons of ore, which has not previously been included in the company's estimates.——The large hoist to be installed at A shaft by the Old Dominion company arrived at the mine June 23.——Drill hole No. 8 on the Live Oak property is 255 ft. deep and still in granite capping.——Beginning July 1, the Warrior Development will send its ore, amounting to 100 tons per day, to the Old Dominion smelter instead of to the El Paso smelter, as in the past.——The Summit Copper Co. is employing a force of 14 men on the 15 claims recently acquired from the Gibson Copper Co. J. P. Hamilton is on the ground making plans for a concentrator to begin treatment of disseminated ore, 100,000 tons of which, having an average copper content of about 3%, is contained in the dump.

Globe, June 28.

MARICOPA COUNTY.

The adit at the Tellurium group, 60 miles northeast of Mesa, has opened the vein when in 180 ft. exposing ore of the same grade that was cut on the surface which assayed $35 per ton.

MOHAVE COUNTY

E. H. Barton, manager for the Frisco Mines & Power Co., operating the Gold Crown group of mines in the Union Pass district, returned from New York several days ago and announced the purchase of a 100-ton mill to be erected at once. The machinery, weighing about 200 tons, is being furnished by the Chalmers-Williams company, and part of it is on the way. Pachuca agitators and Burt revolving filters will be used.——The Desert Power & Water Co. is to add a 1200-hp. Nordberg engine to the Kingman plant, doubling its capacity.——Two Chilean mills are to be added to the Gold Road mill to slime the pulp. This is expected to raise the capacity of the plant to 300 tons per day. In the mine air-shaft No. 2 has reached a depth of 300 ft.; the raise started from the 500-ft. level to connect with this is up 75 ft., leaving only 125 ft. to drive. This shaft will not only enable freer stoping of the 500 ore-shoot, but will be used to handle timbers, steel, and other materials.——The Tom Reed has just finished a new transformer house and is installing another 5 by 22-ft. tube-mill, which will greatly increase its output.——The Cyclopic mine, in the Gold Basin district, has been bonded by a group of New York men and development by sinking will be started at once. The Cyclopic is a deposit of low-grade ore, which is generally regarded as a blanket deposit, and has yielded considerable in a small amalgamating mill. The lowest workings at a depth of 40 ft. show good ore, and the new operators propose sinking a deep shaft.

PINAL COUNTY

The Ray Consolidated Copper Co. is now only operating nine churn-drills, the main effort of the company being devoted to the installation of equipment. At the main shaft preparations are being made to install the hoist, compressor plant, and rock breaker, all of which will be operated by electricity generated at Hayden, where the mill and smelter are being built.——The controlling interest in the Sultana Arizona Copper Co. has been purchased by the Baldwin syndicate of Chicago and the name changed to the Kelvin-Sultana. Over 3000 ft. of underground work has been done, a good body of copper ore opened, and it is now proposed to install a concentrating mill.

YAVAPAI COUNTY

After a test run of several days at the Monte Carlo mill the plant has been shut down for lack of water and sinking resumed. The clean-up resulted in a $500 bar.——At the Octave mine the ore is being drawn entirely from the Joker shaft and the 20-stamp mill is kept in operation night and day. Considerable gold is caught on the plates and a high-grade concentrate shipped.——The mill of the Mildred Gold Mining Co. is nearly completed and will be started in a short time.——At the Yarnell mine T. J. Sparks has cut a station at the mill level and will commence lateral work toward the ore.——The Federal Mining Co., operating on Cherry creek, has purchased a 6-hp. gasoline engine from the Arizona Mine Supply Co., and will install it at the property.——A good body of red oxide copper ore has been struck on the 700-ft. drift in the Haynes property near Jerome. Thomas E. Campbell, the manager, states that he will install an electrical pumping plant within two weeks.——Work has been resumed at the Hull and Cleopatra properties, after a delay of a few days caused by a defective engine.——The orebody is being developed on the United Verde Extension property and the ore piled on the dump.

CALIFORNIA

INYO COUNTY

Asa B. Hall has secured a bond on the Union mine which is one of the oldest locations in the county. The ore is from 12 to 40 ft. wide, the pay-shoot being valued at about $8 per ton for its lead-silver-gold content. Considerable high-grade ore was taken from the property in early days and shipped to the smelters, the vein being opened to a depth of 200 ft. There is now over 1000 tons of milling ore on the dump from previous operations.——The Casa Diablo shipped a $3000 gold bar a few days ago. The mine is now paying all expenses and is expected to become a dividend payer in a short time.——The Keane Wonder, at Skidoo, shipped the regular monthly clean-up for May which amounted to a little less than $20,000.

KERN COUNTY

(Special Correspondence).—Through the agency of C. Grant Illingworth a deal has been closed for the sale of the Cora Dee mine, which is adjacent to the Gold Stone in the Stringer district. The mine was owned by W. Greenwood and has now become the property of the Atolia Mining Co. The Cora Dee has a well developed lode of scheelite averaging from 5 to 10% of tungsten. The sale price is between $3000 and $4000.——The Pearl Wedge, owned by C. G. Illingworth, has ore sacked and ready for the mill which is expected to yield about $3500.——Spurlock and partners on the Merced sent 24 tons to the mill this week, realizing $2400.——The Sunshine Leasing Co. has 100 tons ready for cyaniding which will net from $3 to $7 per ton.——The Halford brothers have taken a lease on the Minnesota group, owned by Gunderson brothers, who have uncovered a vein of low-grade ore, over 3 ft. wide, on the Golden Link, one of the Josephine group.——Watchman brothers, working on the 70-ft. level on the Butte, have run

into a rich vein in the hanging wall, which had been overlooked by the previous lessees. It assays about $200 per ton.——The Manby lease on the Gold Queen, in the Stringer district, has struck a promising vein in the 70-ft. shaft.——Christensen & Dolbear are working in beds of gravel from the washes of old channels in the Stringer district. These contain both gold and tungsten in paying quantities. The Stanford Mining & Reduction Co. of Johannesburg has made several millings of this gravel and has found that the extraction in gold and tungsten runs from $10 to $15 per ton, principally gold.——Pat Byrne and Clyde Kuffel have sunk a 40-ft. shaft in the gravels on the Gold Coin and have struck a bed of gravel 8 ft. deep, which is rich in gold and tungsten.——On the Fuller claim in the same neighborhood a 40-ft. shaft and a 70-ft. drift have been driven, from which a large quantity of pay-gravel also containing gold and tungsten has been taken.——Diedrick, Peterson & McClure, on the Lucky Star, Bremmer group, in the Stringer district adjoining the Santa Ana, have come on a very rich lead of ore, at a depth of 80 ft. which will run about $800 per ton, and are developing the vein.——Thirty feet of good water has been found 600 ft. below the surface in a shaft on the Little Butte.

Randsburg, June 25.

NEVADA COUNTY

The work of re-opening the Blue Lead drift mine at Relief is progressing steadily, operations having again been started in the bedrock adit. The raise that was recently completed did not open the channel, as the bedrock pitched sharply to the north, but the next one is expected to cut the bottom of the channel.——The contractors have completed the hauling of the lumber from Nevada City to the Tarr Mining Co.'a ditch and are now freighting in the machinery that will be installed at the gravel claims.——The grading for the installation of the new machinery at the Fruitvale mine near Moores flat has been completed and the compressor will be set up in a few days. Andrew Fitzgerald is superintendent.——The new 10-stamp mill at the Birchville ia running steadily and 60 men are working at the property.——Work has been resumed at the old Cincinnati Hill mine southwest of Grass Valley under supervision of A. D. Foote. A 4-in. air line from the Massachusetts to the Cincinnati is under construction and as soon as the prospect shaft which has been started to cut the vein is in ore development will be rushed.——The Empire Mines Co. is to build a cyanide annex and will install two Oliver filters.——The installation of the new hoisting plant at the Montana mine in Willow valley has been completed. W. G. Drown is manager.

SHASTA COUNTY

It is reported that the railroad to the Afterthought mine at Ingot will be completed, and work resumed at the property, which has been idle for over two years. S. E. Bretherton is consulting engineer.

SIERRA COUNTY

A 2½-ft. vein containing free gold with considerable arsenical sulphide has been cut by the adit at the Afterthought mine in the Alleghany district. The property is situated on Kanaka creek and is owned by John Carroll and John Allen.——The drift at the Caesar is now in 300 ft. on the vein, which is from 30 to 36 in. wide.——When in 350 ft. the adit at the Sierra Wunder opened seven feet of ore, samples of which panned well.

TUOLUMNE COUNTY

(Special Correspondence).—Preparations have been commenced for extensive development work at the Jumper mine. The shaft will be straightened, the hoist moved to the footwall side, and the 40-stamp mill thoroughly overhauled. It is probable that a steel head-frame will also be erected.——Ore ranging from $75 to $100 per ton is being taken from the Tiger mine, near Saw Mill flat. The strike was made 20 ft. below surface. ——The crew at the Eagle-Shawmut has been considerably increased and 40 of the 100 stamps are again dropping. It is understood that the entire plant will be in operation before long.——The adit being driven to tap the vein at the Experimental Gulch mine is in 630 ft., leaving about 370 ft. of intervening distance.——Work has been resumed at the Remington mine, in the vicinity of Columbia.——Work is being actively carried on at the Mack, the principal development being on the 700-ft. level, where driving and stoping are in progress.——The Jubilee group of six mines, also known as the Hazel Dell group, situated near the Kelts, has been bonded to the Columbia Reduction Co. of Kansas, and underground work will be commenced immediately. The 4-stamp mill on the property will be overhauled and put in readiness to commence crushing ore whenever needed.——The McTarnahan, Stinchfield, and Rosedale gravel claims, in the Mormon Creek district, have been bonded to a company and it is reported that work on a large scale will be commenced at once.

Tuolumne, June 25.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—A rich discovery was made this week at the holdings of the Bard Creek Mining & Milling Co., operating on Lincoln mountain. In running the southeast drift on the Nelsen vein a streak of ore 8 in. wide was cut that assays from 1000 to 2000 oz. silver and from 4 to 7 oz. gold per ton. F. Nelson is manager.——Rendhal & Wilcox, leasing on the Hercules level of the Seven-Thirty mine on Sherman mountain, have opened a streak of smelting ore that is from 7 to 12 in. wide. The

Central City, Colorado.

first shipment of six tons brought a settlement of 475 oz. in silver per ton and 15% in lead.——It is reported that a deal has been closed whereby Eastern capitalists secure possession of the Becker placer. The sale is said to involve a cash consideration of $100,000.——A carload of ore was shipped last week from the Donaldson mine, on Donaldson mountain, that brought a settlement of 1.92 oz. gold and 3.58 oz. silver per ton. The smelting streak is said to be from two to three feet wide, while the shoot has been proved for 135 ft. Fred Nye is manager.——The Cumberland mine was the scene last week of an important discovery, a streak of ore from 10 to 14 in. wide having been cut that is worth from $400 to $450 per ton.

Georgetown, June 25.

GILPIN COUNTY

(Special Correspondence).—A new shaft-house is being constructed at the British mine in Lake gulch. Within a few days a force of men will be at work in sinking the shaft, now down 220 ft., to a depth of 320 ft. S. A. Rank has been appointed manager.——The new 10-stamp mill of the Gilpin-Eureka Mining Co. was started up last week, the capacity being 40 tons per day. J. N. Caldwell, of Denver, is manager.——The Perigo mill was started this week and will treat ores from the Perigo, War Eagle, and Comstock mines.——The Boneta mill, at Idaho Springs, has been leased by the Gilpin American Mining Co., and is being overhauled. When started it will be fed upon ore from the Victor mine, situated at the head of Virginia canyon.——J. H. Nankervis, of Idaho Springs, has taken a bond and lease upon the Delmonico property on Quartz hill. The main shaft, down to a depth of 1300 ft., is being unwatered. ——An air-compressor plant has just been placed in po-

sition at the Clarissa mine in Virginia canyon. The property is owned by Philip Mixwell of Idaho Springs.

Central City, June 25.

LAKE COUNTY

The adit at the Siwatch group, on Sugar Loaf mountain, is progressing at the rate of 200 ft. per month, the face now being a distance of 1200 ft. from the portal. It is expected that the mineralized zone will be opened within the next 800 ft.——Hoisting has been suspended at the Castle View shaft while portions of the timbers are changed and the guides lined.——The Emmet mine, which is leased by the Small Hopes Mining Co. to Frank Zaitz, is shipping low-grade copper-lead ore regularly.——A new electric hoist has been installed at the Continental by Fred J. McNair who has a lease on the ground and connections made with the power company's wires.

SAN JUAN COUNTY

At the Gold Nugget mine, near Silverton, which was taken under lease last May by J. T. Janes, several shoots have been opened that assay over $30 per ton, and a body of ore 300 ft. long and assaying about $12 per ton has been stripped on the surface. The latter will be cyanided. The Nugget is situated in Maggie gulch and is surrounded by a number of active producers.——Conditions at the Frank Hough mine are better than at any time since the mine resumed operations. The outside bins contain 800 tons and the chutes in the mine contain over 200 more, all of which is said to be of excellent shipping grade. A station has been cut on the 400-ft. level and a winze is being sunk on the ore which contains a high percentage of bornite.

TELLER COUNTY

F. L. Shaw who recently obtained a lease on a block of ground in the Hiawatha claim in the Cripple Creek district has opened the shoot at a depth of 75 ft. and is shipping two carloads to test its value.——The debts of the company operating the Agnes claim on Beacon hill have been settled and work will be resumed on the property.——Grading has been started at the new shaft of the El Paso Consolidated on the north end of the property and a powerful hoist will be installed. Miners are sinking from the surface and raising from the fourth level, and it is planned to have the shaft in operating order by the time the workings are drained by the Roosevelt tunnel.——The new headframe at the shaft of the Midget mine has been completed.——The lessees on the Ajax mine have opened a shoot of high-grade ore on the 400-ft. level 1200 ft. north of the main shaft. Some of the ore has assayed as high as $300 per ton.——The Carol Mining Co., which has been stoping about 400 tons per month from the Monument mine has stopped mining temporarily to retimber the shaft from the 700-ft. level.——The plant at the Cresson, which was destroyed by fire last April, has been replaced and mining resumed with a force of 125 men.——The Mitchell lease on the Pinnacle has opened a shoot of $90 ore at a depth of 350 ft.——The raise on the Knife Blade vein in the American Eagles mine is opening a seam that has widened out to several inches of 6-oz. ore.

IDAHO

BLAINE COUNTY

(Special Correspondence).—The dump of 20,000 tons of tailing at the North Star mine, on the east fork of the Wood river, is to be milled by Allen & Hanson, of Utah, on a royalty basis. The dump contains a good grade of silver, lead, and zinc ore. The lessees are to pay a royalty of 25%. John Williams, of Hailey, who is interested in the North Star, states that in the mine there is a 16-ft. body of silver-lead-zinc ore, and that a one-car shipment made some time ago ran 45% zinc.——The Wolf Tone mine, situated on Deer creek, is being further developed by the Eclipse Mining Co., and is in charge of H. E. Pomeroy. Former development was at the surface, and to obtain greater depth a cross-cut is being driven from Wolf Tone creek. It has been advanced 1700 ft., and work is to be continued till the principal contact vein between limestone and quartzite is tapped, which will be at about 700-ft. depth.

Hailey, June 24.

SHOSHONE COUNTY

The Monarch Mining Co. has sold a two-thirds interest in the Monarch mine near Murray, to the Coeur d'Alene North Fork Mining & Smelting Co. for $175,000. The company also has a lease to work the remaining one-third interest and an option to buy it. Seventy-five thousand dollars has been paid in cash and a mortgage for $100,000 given on the two-thirds interest. The lease provides that the new company shall work the property as a whole and issue to the Monarch company $499,900 of its paid up and non-assessable stock and $100 capital stock to a person to be named by the selling company. After the note for $100,000 is paid the new company shall pay one-third of its net earnings to the Monarch company.——W. M. Walker and J. Leicht, of Spokane, have taken an option for $30,000 on the Emma group of eight lode claims which is situated in Gold Run gulch, three-quarters of a mile from the town of Murray, and is one of the best known gold properties in the camp. In an early day it was a producer of much rich ore, but lack of transportation facilities discouraged the owners and little has been done since then. Work has been started in a new adit in which some good ore is exposed.

MISSOURI

JASPER COUNTY

A good discovery of galena ore has been made at a depth of 14 ft. on the Lone Pine ground northeast of Knight's station.——The shaft at the Hallowe'en has been unwatered and development started on the orebody. The shaft is down 180 ft. The derricks at the new mill in Stotts City have been completed and the inclines started.——The Vinegar Hill Mining Co., of Joplin, has leased the Julia West ground and is preparing to prospect it.——The Keystone mine has been started again after a few days' stop on account of the heavy rains.——H. L. Kramer, who has a lease on the Marion Staples land, is to erect a mill and develop the property. The pump in the shaft which is at the 150-ft. level has been started, and drifts will be run in the ore which is largely calamine and rosin jack.——J. A. Waterhouse has installed an 80-hp. boiler on the Clark land and is unwatering the shaft which is reported to have opened zinc ore from the depth of 190 to 225 ft. A number of drills on adjoining land are said to have cut ore at about the same depth.

NEVADA

HUMBOLDT COUNTY

(Special Correspondence).—The double-compartment shaft of the International Metal Mining Co. is being rapidly unwatered. The Old Pride of the Mountain vein has been proved to a depth of 135 ft.——The new mill of the National Mining Co. has arrived at the camp. It is of the Lane Chilean type with a capacity of 40 tons per day. The mill will treat the low-grade ore from the mines.——The Laurel company is shipping its first consignment of ore.——Sixty men are on the payroll at Jarbidge, nearly double the number employed last month.——The first lease north of the Pavlak shaft has opened three feet of ore assaying $16 to $44 per ton. A small seam of high-grade quartz has also been uncovered.——The Free Gold company has commenced operations with two shifts.——The Tacoma company is driving an adit and sinking a shaft on its holdings.——Butte interests have acquired a group of claims near the main properties.——At the Pick & Shovel work is progressing in two shafts and an adit. The main shaft is down 50 ft.——The Rye Patch Consolidated is driving on three feet of ore said to average $100 per ton. The ore contains silver and lead. D. W. Jeffs is manager.

Winnemucca, June 24.

LYON COUNTY

The Bluestone Extension Mines Co., which owns 180 acres just north of the Bluestone mine, has installed a new hoist and will sink the shaft, now down 65 ft., to the 500-ft. point, cross-cutting to the vein every 200 ft. There is a large amount of 3% copper ore blocked out in the Bluestone, and the Extension operators believe that they have the same contact that developed the ore in the older prop-

erty.——Jules Labarthe, who is in charge of the construction of the new smelter at Wabuska for the Mason Valley Mines Co., is authority for the statement that the plans for the smelter were nearly complete and that contracts for the grading would be let in a short time. Grading for the spur track from Wabuska to the smelter-site is to be started at once and will be completed by the end of July.——There are 16 men working at the Nevada-Douglas, and plans are being prepared for the installation of an automatic distributor which will convey the ore to the bins. A three-ton skip is also being installed in the incline shaft.——The Yerington Gold Co., which owns the group south of the Nevada-Douglas is to install a hoist and commence sinking. Operations are to be resumed at the Honest Endeavor. The company will complete the cross-cut to the ore that was started at the 150-ft. level.

NYE COUNTY

(Special Correspondence).—The south drift from the 700-ft. point of the Montgomery-Shoshone shaft has opened an orebody, but development has been suspended owing to the strong flow of water which forced the miners out. A diamond-drill has been installed at the top of the winze and is prospecting the ground, which is all virgin territory. ——The Pioneer lease is sending to the Mayflower mill 50 to 60 tons of ore per day which averages about $30 per ton, and is principally from the dumps. Besides this, from 50 to 100 tons per week of high-grade is shipped to smelters.——The Chambers lease on Original Bullfrog has recently made several small shipments of high-grade ore to Goldfield. On the adit-level about 15 ft. of gold-silver ore is exposed.——The Vulcovich lease on Tramp Consolidated has opened a narrow seam of rich ore.——The Eclipse company recently sent out two bars of bullion valued at $7000, the result of a 10-days' run of the mill.——The Bullfrog-Mohawk has installed a duplex pump, electrically operated, and will commence active development.——The Montgomery Mountain is planning to resume operations as soon as the assessments on the old stock come in. Stock in the new company will be given for the old stock, when the 3c. assessment accompanies the old certificates.

Rhyolite, June 17.

Though the recent decision of Judge Stevens at Goldfield, regarding the apex rights of the Round Mountain Mining Co., was unfavorable to that company, the management is planning to install new machinery and increase the output to over 200 tons per day. The case is to be appealed. The Round Mountain Water & Power Co. has secured leases from the Round Mountain Mining and the Round Mountain Daisy companies on the pipe-line and will continue its placer operations.——Hoisting and shipping of ore was resumed last week at the MacNamara at Tonopah after a temporary suspension, and 130 tons of ore was forwarded to the smelter. There is a good showing underground and the management expects to ship regularly.——On June 18 the Montana-Tonopah shipped the regular semi-monthly lot of bullion and cyanide precipitate. Operations are being advanced on every level between the intermediate above the 390 and the 765-ft. levels, and enough ore is in sight to crowd the capacity of the 40-stamp mill for some time to come.

STOREY COUNTY

The water in the C. & C. shaft at Virginia City has been lowered about 250 ft. below the 2350-ft. level and the timbers are found to be in good condition though there is much débris in the workings.——Last week 23 cars which averaged $12.18 were taken from the southwest drift from the east cross-cut on the 2400-ft. level of the Ophir. The drift is entirely in vein matter and is exploring ground that has never been prospected before. The northeast drift on this level is now out about 50 ft. the face showing seams of quartz.——The west cross-cut on the 1700-ft. level of the Consolidated Virginia run from a point 51 ft. up the raise has been stopped and a south cross-cut started which is now in ore that assays from $6 to $7 per ton. The ore broken in the stopes on the 1800-ft. level assays from $9 to $10 per ton.——At the Ward shaft the west drift on the 2000-ft. level is now out over 40 ft. from the shaft and on the 2100-ft. level the installation of pumps No. 3 and 4 has been completed.

WHITE PINE COUNTY

(Special Correspondence).—The inrush of water on the lower level of the steam-shovel pit of the Nevada Consolidated a short time ago, which engulfed one steam shovel, did not prove as serious as was at first apprehended. The water has since practically disappeared, but there is no doubt that the water-level has been reached, and it will be impossible to take another slice from the bottom of the pit without providing for pumps to relieve the probable inflow of water. The sulphide ores extend for a depth of 150 ft. beneath the present floor of the pit. Two steam-shovels are now working on ore on the second level of the pit and loading about 6800 tons of ore per shift. The frame work has been completed at the concentrating plant of the Steptoe reduction works of the Nevada Consolidated for a testing plant of the tailing, where a number of experiments will be tried. The company has been saving only from 71 to 72% of the value of the ores treated in its concentrator, hence it has been suffering a heavy loss, which it hopes to largely avoid in the future.——The sump at the 1200-ft. level of the Giroux shaft of the Giroux company has been cemented and the cementing of the pumping station has been commenced. The station is 21 by 105 by 15 ft., and will be equipped with one 1200 and two 600-gal. pumps.——A pumping plant will be erected at once on the Brilliant shaft of the Ely Consolidated and after the mine has been unwatered the vein will be picked up on the 500 and 625-ft. levels, and further development undertaken. The company also contemplated the installation of a pumping plant on its Zack shaft, which is flooded with water to the 400-ft. level. This property has been extensively developed above the water-level and shows extensive bodies of carbonate and sulphide ores which will be developed at greater depth.

Ely, June 24.

UTAH

BEAVER COUNTY

Joseph V. Coyle has opened an 18-in. vein on his claims, six miles southeast of Minersville, that assays from $3 to $50 per ton.——The Commonwealth Mining Co. is opening ore that assays 200 oz. silver per ton.

JUAB COUNTY

The repairs to the pump on the 1600-ft. level of the Gemini have been completed. The Ridge & Valley mine, which is operating through the Gemini, is stoping on the 1500 and 1600-ft. levels and both properties are forwarding heavy shipments.——The motor which was ordered some time ago for the Yankee Consolidated should arrive at the mine any day and will be set in position at once. All the other machinery is now in place and the buildings have been completed.——The shaft at the Eagle & Blue Bell has been retimbered to the 200-ft. level and sinking resumed. At the same time a raise was started from the 1000-ft. level to meet the shaft.——The Victoria shaft, which is down 550 ft., is being retimbered where necessary and will be sunk to the 1000-ft. level.——Iron Blossom is stoping in the No. 1 and 3 workings and will commence driving on the 1700-ft. level in the early part of this month.——The shaft at the Colorado is down 500 ft., and the station and sump are being cut at that level.——The drift which was driven into the Governor ground from the Star workings, is expected to open the ore in a short distance.——It is reported that the King William is to resume work shortly.

SUMMIT COUNTY

At a recent meeting of the board of directors of the Scott Hill Mining Co. an assessment of one-quarter of a cent per share was levied, and it was decided to continue work in the face of the adit which is now in 140 ft. It is thought that the contact will be opened in the next 50 ft.——About a dozen men have been employed at the Little Bell for the past few weeks preparing for the installation of new machinery. Underground the mine is said to be in excellent condition, several large bodies of milling ore having been opened in addition to the high-grade.——By the middle of the month the management of the Daly-Judge expects to

have the new electrical equipment in the concentrating plant at Park City all installed. The transmission line leading from the mine to the mill is being strung and the power will be furnished by the Snake Creek Power Company.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—A second shipper was added to the Nelson list during the past week when the Athabasca mine, on the hill behind Nelson, sent 26 tons of select ore to the Trail smelter.——A gold bar was brought to Nelson during the week from both the Nugget and Queen mines, Sheep creek.——The Canadian Collieries Co. has been organized to operate the Extension and Comox collieries, and increased production of coal is promised.——In Portland Canal district, the most important work is that of the Portland Canal Mining Co., which has erected an aerial tramway 8500 ft. in length, with 2100 ft. difference in altitude between terminals; it is also equipping a 75-ton unit of its concentrating mill, and preparing to install a 6-drill air-compressor.——There is a prospect of the Hidden Creek Copper Co.'s mine, on Observatory Inlet, being again worked shortly. This has been developed by an adit to a depth of 500 ft., and above this level there is more than 300,000 tons of ore blocked out. Steps are being taken to put in a 500-ton smelter.

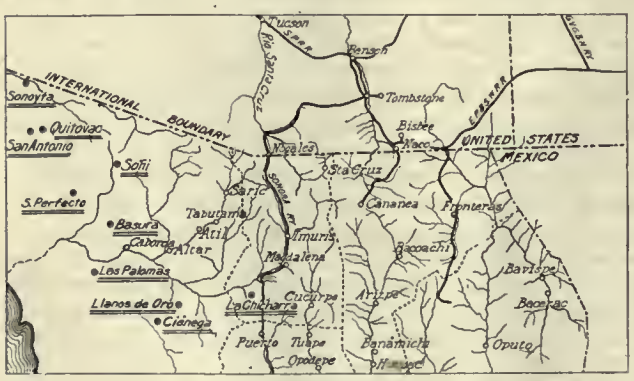
ONTARIO

The drift on the 225-ft. level of the Little Nipissing, on Peterson lake, has opened a 14-in. vein that contains a high percentage of native silver and smaltite. The lease on the property, which is held by the Peterson Lake Mining Co., has been extended five years giving the company eight years to operate the mine.——The drift on the 200-ft. level of the Crown Reserve is in the conglomerate again and is being driven to intersect the leads cut by the diamond-drill in the prospecting. The Victoria vein which was opened in May is proving one of the best leads found in the Cobalt district, some of the assays having run as high as 6000 oz. silver per ton, and will soon be opened enough to be the main reserve of the company.

MEXICO

CHIHUAHUA

The directors of the Rio Piata Mining Co. declared the regular 2% quarterly dividend payable to stockholders of



Northern Portion of Sonora.

record June 20. Over 200 tons of tailing was treated at the mine in May and 57,136 oz. of silver recovered. Seventy bars of silver valued at $500 each were shipped from the mine early in June.

SONORA

A company of English capitalists has been organized under the name of the Tomminil Mining Co. to take over the Rosario and adjacent claims in the Altar district. The mines are antiguas and have good production records.——The Mina Juarez, situated near Caborca, has cleaned up the mill and hung up the stamps till more ore can be blocked out by the underground work.——The Marguitos Mine Co. has opened a 7-ft. vein in the San Cortez property that assays about 40 oz. silver per ton. There is a large amount of ore in the mine that assays from 12 to 15% lead with 16 oz. silver per ton.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

FRAUDULENT ENTRY ON COAL LANDS

By a fraudulent entry on coal lands a claimant acquired no rights therein, and his alleged title is void. Neither could he acquire any title to a coal mine thereon pending cancelation of such fraudulent entry, and his obtaining an injunction on the strength of his supposed right before cancelation of his entry was said to be a fraud on the jurisdiction of the court.

Baldwin Star Coal Co. *v.* Quinn, (Colo.) 105 Pac. 1101, Dec. '09.

MINING PARTNERSHIP—AUTHORITY OF PARTNERS

Where the members of a mining partnership were not able to agree, it was held that those having the majority interest had the right to control the management in all things necessary and proper for the operation of the mine, and they could not be held liable in an accounting except for culpable negligence, breach of duty, wrongful conduct, or diversion of the property from the business of the firm. And in an action for dissolution, accounting, and winding up of the mining partnership, an inferior court was not authorized to enter a personal decree against one partner in favor of another for the balance found due him on incomplete settlement. The social property should first be reduced to money and the proceeds applied to the discharge of the partnership liabilities, including any balance found due on final settlement from one partner to another, and then a decree over on final settlement for any balance that might remain. And in such a settlement one partner who had paid the share or interest of another in the operating expenses would be entitled to interest thereon, as against the delinquent partner, on dissolution and final settlement and winding up of the partnership.

Bartlett & Stancliff *v.* Boyles, (W. Va.) 66 Southeast. 474, Nov. '09.

DOWER IN MINING PROPERTY

Coal in place is said to be 'real estate' within the meaning of a statute giving a wife dower in all her husband's real estate, of which he was seised in fee simple at any time during the coverture.

Reynolds *v.* Whitecarver, (W. Va.) 66 Southeast. 518, Dec. '09.

INJURY TO MINER—FELLOW SERVANT

The owner and operator of a mine cannot be held liable for the mistake or incompetency of the certified foreman required by the statute of Pennsylvania, where the statute invests such foreman with power to compel compliance with his directions, so far as they relate to the safety of employees. And the Supreme Court of Pennsylvania has just decided that a mine foreman is a fellow-servant with the other mine employees of the same employer engaged in a common business, and the employer is not liable for injury due to the negligence of such foreman. But it is not clear whether the court referred to the negligence of the foreman required by the statute called a "certified foreman," or an ordinary foreman employed by the operator of the mine.

Golden *v.* Mt. Jessup Coal Co., (Pa.) 73 Atl. 1103, June '09.

DEVISE OF COAL LANDS

A testator by his will devised to one person the surface of certain lands described, and gave to another the coal under such lands. On a construction of the will in a controversy between the devisee of the lands and the devisee of the coal, it was held that the will gave to the former the land in fee simple, except the coal under it, and that it gave to the latter the coal, with the right to mine it, including the necessary roadway and the use of the surface necessary to the proper operation of the mine.

Myher *v.* Myher, (Mo.) 123 Southwest. 806, Dec. '09

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

HOWARD D. SMITH is in London.

C. K. LEITH has returned from Cuba.

MAX JUNGHANDEL is in San Francisco.

CHARLES MACNEIL has gone to Europe.

C. S. HERZIG is expected in San Francisco.

DAN O'BRIEN, of Colombia, is in San Francisco.

FRANCIS DAAKE has gone to southern California.

W. F. FARNHAM, of Chicksan, Korea, is in San Francisco.

FRITZ WOLF has gone to Amador county on professional business.

A. H. HOWE went to New York to assist in welcoming Mr. Roosevelt.

J. E. SPURR was in San Francisco on his way from Tacoma to Tonopah.

LOUIS J. MAYREIS has returned to Coliahuasi, Chile, from Carangas, Bolivia.

H. KILBURN SCOTT has sailed for British East Africa on professional business.

THOMAS D. MURPHY is manager of the El Favor mine at Hostotipaquillo, Mexico.

READ E. MILLEA is examining, with a view to purchase, a lead property near Clyde, Idaho.

C. H. GORDON and L. C. GLENN have been appointed Associate State Geologists of Tennessee.

O. T. SCHINBECKLER, of the Oriental Con. M. Co., in Korea, is spending his vacation in California.

RUSH M. HESS has accepted a position with the Real del Monte y Pachuca, at Pachuca, Mexico.

NORMAN C. STINES has gone to Siberia to assist J. POWER HUTCHINS in an examination of placer fields.

GUY M. VAIL, of Portland, Oregon, has gone to Fairview, Nevada, to supervise the construction of a mill.

WILLIAM A. FARISH, Jr., has been appointed superintendent of the Keane Wonder mine, Death Valley, California.

L. D. RICKETTS has been in a New York hospital as a result of a fall in the mine at Cananea. He is recovering nicely.

J. D. HUBBARD, of the Oriental Con. M. Co., arrived from Korea on the *China* and will spend July and August at Santa Clara.

F. B. WILDER, chemist for the Chino Copper Co., of Santa Rita, New Mexico, has resigned to accept a position at the Copper Queen smelter at Douglas, Arizona.

M. K. RODGERS, of Seattle, Washington, is doing some work on the Dunton, an extension of the Cracker Jack vein, on Prince of Wales Island, Ketchikan district.

C. L. HERRICK has resigned as Western representative of *Mines & Minerals* to accept a position at Lebanon, Ohio. He will be succeeded at Denver by GEORGE F. DUCK.

WALTER O. SNELLING, chief chemist of the explosives section of the Technologic Branch of the United States Geological Survey, left Seattle, Washington, on June 17, for Alaska, to investigate methods of blasting.

A. CUNNINGHAM, a graduate of the school of mines of the University of Washington, Seattle, Washington, is about to leave for Chena, in the Fairbanks country, Alaska, to erect and operate a 'limited custom' 10-stamp mill.

A. W. MORRIS, who for the past two years was in charge of the cyanide plant at the Black Mountain mine, Magdalena, Sonora, will have charge of the new plant of the Zambona Mining Co., at Alamos, Sonora, after July 1.

GEORGE J. YOUNG, of the Mackay School of Mines, at Reno, Nevada, has returned from an eight months' trip, during which he visited numerous schools of mines in the Eastern States, Canada, Germany, France, and Great Britain, seeking information relative to methods and equipment.

JOPLIN LEAD AND ZINC PRICES

The *News-Herald* figures for the week ended June 18, 1910, are as follows:

The high price for zinc blende was $44 per ton and the average on all lots was $39.85 compared with $40.20 of the previous week.

Spelter was steady at $5 which was lower than last week, the closing price then being $5.05.

Calamine ores brought as high as $27 per ton, the average being $22.21. On a 40% basis the price ranged between $20 and $23 per ton.

Lead ore was unchanged at $49 per ton, with an average for all lots of $48.84 compared with $48.75 for the previous week. The pig-lead market was unchanged at $4.22½.

Below are given the value of shipments from each district with a summary for the district:

Joplin: Blende, $32,760; calamine, $528; lead, $8624. Total, $41,912.

Webb City-Cartersville: Blende, $73,040; lead, $16,856. Total, $89,896.

Galena: Blende, $8920; lead, $2450. Total, $11,370.

Granby: Blende, $3200; calamine, $200; lead, $315. Total, $3715.

Duenweg: Blende, $21,480; calamine, $594; lead, $4116. Total, $26,190.

Miami: Blende, $7688; lead, $3600. Total, $11,288.

Aurora: Calamine, $2618.

Zincite: Blende, $3608.

Badger: Blende, $3084.

Oronogo: Blende, $10,243; lead, $23. Total, $10,266.

Carthage: Blende, $3770.

Stotts City: Blende, $4160.

Quapaw: Blende, $2457; lead, $912. Total, $3369.

Sarcoxie: Blende, $1080.

Spring City-Spurgeon: Blende, $2120; calamine, $814; lead, $1372. Total, $4306.

Alba-Neck City: Blende, $17,220; lead, $115. Total, $17,335.

Peoria: Calamine, $132.

Summary for the district: Blende, 9,926,290 lb.; calamine, 619,150 lb.; lead, 1,572,930 lb. Values: Blende, $196,827; calamine, $6886; lead, $38,388. Total, $242,101.

Total for 25 weeks: Blende, 254,030,885 lb.; calamine, 20,630,850 lb.; lead, 40,664,070 lb. Values: Blende, $5,338,351; calamine, $257,582; lead, $1,011,651. Total, $6,657,484.

JAMES P. WALLACE, who died at Nogales, Arizona, June 19, was well known throughout the West, having conducted mining operations for thirty years in various States and Territories, especially in Colorado and Mexico. Dr. Wallace was taken ill at Culiacan and died while on his way to his home in Colorado Springs, to which place his body was taken for burial. He was a member of the American Institute of Mining Engineers, the Colorado Scientific Society, and a frequent contributor to the technical press. Probably his best known work is his book 'A Study of Ore Deposits for the Practical Miner', which has been widely read and used.

Current Prices for Chemicals

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

	Min.	Max.
Acid, sulphuric, com'l, 66°, drums, 100 lb.	$0.90	$1.25

Zinc sheet, No. 9—18 by 84, drum, 100 lb.	9.50	10.50

THE HECLA MINE HOIST

Perhaps no electric hoisting plant has attracted more attention from the mining men of the entire country than that of the Hecla Mining Co., at Burke, Idaho; the American Institute of Mining Engineers during their 1909 tour, made the trip to this mine for the express purpose of inspecting the plant. The power available for this plant is 3-phase, 60-cycle current, ranging from 2080 to 2300 volts. The motor generator, Fig. 1, is self-contained, having a cast-iron base, four bearings, and shaft. A 450-hp., 3-phase, 60-cycle motor drives the direct-current generator, which is

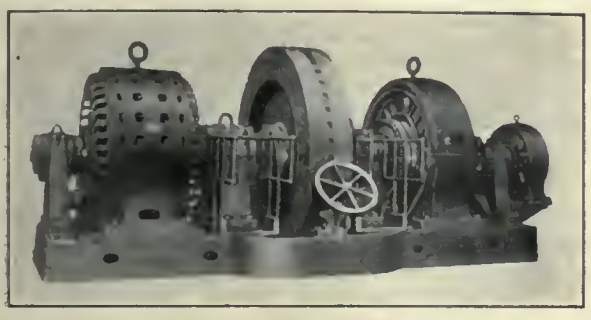

Fig. 1. Motor-Generator Set.

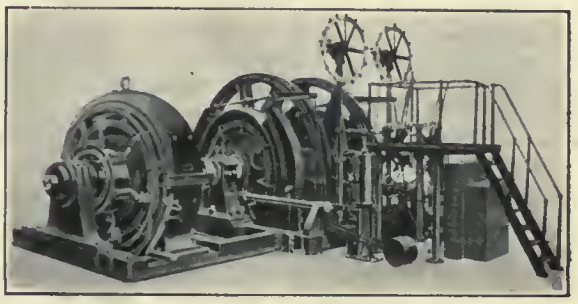

Fig. 2. Hoist Erected in Shop.

Fig. 3. Engine Room Showing Hoist in Place.

equipped with commutating poles to enable it to handle full load current at any voltage between 0 and 600. The flywheel, weighing 30,000 lb., is mounted on the shaft between the motor and generator, while the direct connected exciter is carried upon the shaft extension at the end of the set. The direct-current, 550-hp., 600-volt, hoist motor, operating at 60 rev. per min. (Fig. 2), is direct-connected to the main reel shaft by a flange coupling. The control of the direct-current circuit for operating the hoist is obtained by means of a lever, the forward movement of which starts the hoist in one direction, and the backward movement in the opposite direction. This lever is direct-connected to a reversing field rheostat with a large number of points; since it is used to vary the generator voltage instead of cutting resistance into and out of the hoist-motor armature circuit, economical operation is secured at all points even when conditions necessitate running at lower than normal speed. All the operating levers have the same direction of throw with a movement of less than 30 inches. They are conveniently grouped upon a raised platform consisting of an iron frame and hardwood floor, with a suitable stairway leading from the engine-room floor to the platform, and a brass hand rail enclosing the stairway and platform. The entire electrical equipment described above was supplied by the Westinghouse Electric & Manufacturing Company.

The hoist, Fig. 2 and 3, which was built by the Wellman-Seaver-Morgan Co., consists of two reels, each capable of holding 2500 ft. of ¾ by 4 in. flat rope. Under normal conditions the hoist operates balanced; that is, the empty cage descends as the loaded cage is raised. If desired, however, either reel may be operated independently of the other. The winding diameter of the reel varies from a minimum of 5 ft. when empty, to a maximum of 13 when the entire 2500 ft. of rope is wound up. Each of these reels is fitted with a Webster, Camp & Lane band friction clutch, post brake, and indicator. The brakes, which are operated by means of combined air and oil cylinders and heavy counterweights, are so designed that they are set by the weights and released by means of air cylinders. This hoist has a maximum hoisting speed of 2400 ft. per minute, and will handle an unbalanced load of 16,000 lb., including rope, from a depth of 2500 ft., yet its operation is the acme of simplicity.

The complete equipment, including the motor-generator set, hoist motor, slip regulator, switchboard, and hoist, weighs over 300,000 pounds.

The operation of large electric hoists, with mutual satisfaction to the mining company and the power company, has, during the past few years, received careful consideration and today there is no question but that this problem has been satisfactorily solved. With the introduction of the polyphase alternating current generators and high tension transmission lines, electric power has become available in most of the great mining districts. The simplest method of utilizing this power for hoist work is through the direct application of an alternating-current induction motor. If the capacity of the hoist is comparatively small, this is quite satisfactory, but where heavy loads must be handled at high speed, the peak due to acceleration of the moving parts, is often far in excess of the average requirements of the hoist, in which case, if the current is purchased from a power company which also carries a lighting load, the voltage fluctuation at each recurrence of the hoist-cycle peak will prove most objectionable. If the hoist is placed at the end of a long transmission line, an excessive amount of copper must be used to prevent an undue drop in the voltage during the maximum demand. In any case, the power company must install all its equipment with reference to peak instead of the average load and must charge accordingly. To meet these conditions the fly-wheel motor-generator type of hoist has been developed. The essential parts of such a hoist system are:

(A) A shunt-wound direct-current motor, geared or coupled to the hoisting drums.

(B) A fly-wheel motor-generator set consisting of: (a) An alternating-current induction motor with variable external secondary resistance. (b) A direct-current shunt-wound generator with auxiliary commutating poles. (c) A heavy fly-wheel mounted on the motor-generator shaft. (d) A direct-current exciter for separately exciting both generator and hoist motor.

(C) A slip regulator which by varying the secondary resistance of the alternating-current motor causes it to slow down under heavy loads.

(D) A suitable controller for varying and reversing the direct-current generator field current.

The armatures of the direct-current generator and hoist motor are connected in series and the field of each machine is separately excited, constant full field being maintained on the motor. The hoist is started by applying a gradually increasing field to the generator, thus causing a proportionate voltage to be impressed upon the armature of the hoist motor. When the load on the alternating-current motor reaches a pre-determined limit, resistance is automatically cut into its secondary circuit by means of the slip regulator. The speed of the motor-generator is thus reduced and a portion of the stored energy in the fly-wheel utilized in overcoming the peak of the hoisting cycle, with a minimum demand on the power system. In stopping the hoist at the end of a cycle the generator field is gradually weakened so that any excess energy stored in the descending cage, rotating hoist motor, and drums, is returned to the fly-wheel through the direct-current generator which momentarily acts as a motor, receiving electrical energy from the hoist motor, the functions of which are also momentarily reversed. To reverse the hoist, the field of the generator is reversed, causing the motor to rotate in the opposite direction. The heavy peak loads are thus eliminated from the line and the wear on the mechanical brakes is much reduced. Since the current handled by the controller is small, a great many steps can be provided, giving the operator an elastic and sensitive control under all conditions.

JULY DISBURSEMENTS for dividend and interest will total close to $235,000,000. Actual figures show $231,785,000, compared with $215,245,000 in the same month of 1909, $189,866,000 in 1908, and $198,297,000 in 1907. Dividends aggregate, to date, about $87,114,000, against $82,308,000 in 1909, $75,723,000 in 1908, and $83,259,000 in 1907. American Tobacco preferred disburses $1,180,336 and General Electric $1,303,576.

CATALOGUES RECEIVED

The WOOD DRILL WORKS, Paterson, New Jersey. 'Rock Drills'. Illustrated. 30 pages. 6 by 9 inches.

THE TRENTON IRON CO., Trenton, New Jersey. 'Wire Rope and Fittings'. Illustrated. 48 pages. 3½ by 6¼ inches.

The NEW YORK ENGINEERING CO., New York. 'The Empire Hand Prospecting Drill'. Illustrated, 22 pages. 6 by 9 inches.

THE AMERICAN WELL WORKS, Aurora, Illinois. Bulletin 115. 'American Air Compressors'. Illustrated. 80 pages. 7½ by 10½ inches.

ORENSTEIN-ARTHUR KOPPEL CO., San Francisco and Los Angeles. 'Koppel Shoes and Dies, Hercules Brand'. Illustrated. 20 pages. 6¼ by 8¼ inches.

COMMERCIAL PARAGRAPHS

HAFF & COLWELL BROS., Ely, Nevada, have lately issued a large wall map of White Pine county, Nevada.

ALGERNON DEL MAR has established his office at 410 Union Trust Bdg., Los Angeles, and is specializing in stamp-mill and cyanidation consulting work.

The WISCONSIN ENGINE CO., Corliss, Wisconsin, advises that George B. Foster has been appointed Chicago sales manager and that his office will be in the Fisher building.

THE TERRY CORE DRILL CO. advises that the Argentum Mines Co. is installing a Terry core drill for prospecting below the lower levels of its mine on the Foster property in Ontario, Canada.

The C. W. HUNT CO., New York, builders of coal handling, conveying, and hoisting machinery, has opened offices at State Bank building, Richmond, Virginia, and also at 607 Rhodes building, Atlanta, Georgia, with W. F. Lee, for several years preliminary engineer to the company, in supervision.

THE NELSON IRON WORKS, of Nelson, British Columbia, has taken over the business and stock of the Rossland Engineering Works, of Rossland, and will succeed that company as British Columbia agents for the SULLIVAN MACHINERY CO., of Chicago. An increased stock of Sullivan rock-drills, diamond-drills, hammer-drills, air-compressors, and supplies for these machines will be maintained at Nelson.

The ALLIS-CHALMERS CO. has received from the United States Steel Corporation additional orders for six gas engine-driven electrical units which will increase the corporation's power-plant at Gary, Indiana, 25%. The 25 engines which the Allis-Chalmers Co. has installed in this plant, and the order just secured, will make a total of 31 gas engines with a combined capacity of 150,000 hp., making it the largest power-plant of its kind in the world. These units will operate on blast-furnace gas.

SMITH, EMERY & CO. announce that they have secured the services of A. W. Conner, civil engineer, who has for several years been associated with the Illinois Steel Co., at Chicago, and has been for the last two years employed as engineer of erection in the company's new plant at Gary, Indiana. Mr. Conner is thoroughly equipped by experience, and is a graduate of Perdue University. He will have charge, as manager, of Smith, Emery & Company's iron and steel inspection department, covering San Francisco, Los Angeles, Seattle, Pueblo, and Birmingham.

LUCUIS I. WIGHTMAN, for the past six years advertising manager for the Ingersoll-Rand Co., has resigned his position, the resignation taking effect August 1. He will open an office in New York City as an independent specialist in machinery advertising, handling the accounts of manufacturers of machinery and engineering products. Mr. Wightman brings to his new enterprise qualifications peculiarly fitting him for this line of work. His broad acquaintance in the world of trade and technical journalism, his understanding of advertising mediums and methods, and his intimate knowledge of engineering in many phases, will prove invaluable to those whose advertising accounts are placed in his charge.

TABLE OF CONTENTS

EDITORIAL

THE AMERICAN SOCIETY for Testing Materials, one of the most useful of the smaller engineering organizations of the country, has been in session at Atlantic City. The meeting was called to order by Mr. Robert W. Lesley, vice-president. Mr. Henry M. Howe was elected president to fill the place made vacant by the death of C. B. Dudley, so long prominently connected with the activities of the society.

LAKE traffic is heavy this season and marks a large increase in industrial activity in the Middle West. Freight movement up and down Detroit river this year has been nearly double that for 1909. In May, according to the Bureau of Statistics, merchandise shipments on the Lakes were 80 per cent greater than last year and a million and a half tons more than in 1907, the record year. Iron ore shipments for the month were 6,005,329 gross tons and from the opening of the season to June 1, amounted to 7,642,773 tons, more than double the 1909 shipments and considerably in excess of those for 1907. Coal traffic figures tell the same tale, the shipments for May 1910 being 65 per cent above those for May 1909.

LOS ANGELES is hoping to have Mr. Roosevelt for a guest during the meeting of the American Mining Congress, a hope which will be shared by the whole West. Mr. Gifford Pinchot and Mr. James R. Garfield, of the famous tennis cabinet, have already promised to attend prepared to defend the conservation policies, but if Mr. Roosevelt himself can be induced to come the convention is likely not only to be interesting and influential, as is already assured, but of large historical importance. It is becoming clearer every day that some hard fighting must be done before a really effective constructive program relating to the public lands can be carried through and the sooner each side be compelled to submit its claims to open criticism the better. The meeting of the Mining Congress will afford a particularly appropriate occasion for such a debate.

TUNNEL driving methods are of perennial interest. In the *Engineering Record* of June 25 details are given regarding progress and methods in connection with the new Buffalo water works tunnel. The work here differed from that in mines in that it was done under compressed air owing to danger of influx of water. The rocks were sedimentary, flint, limestones, and shale, but in many particulars the conditions were not so dissimilar as to preclude comparison with mining tunnels. Of especial interest is the fact that when a change was made from one to three drilling crews per day the progress was increased 100 feet per month over the average for the preceding

twelve months, and 90 feet over the average for six. This was accomplished at an increased cost for labor and materials of less than $2000 per month and with practically no increase in general expense. A 96 per cent explosive was tried without any satisfactory increase in efficiency over the lower-grade dynamite. The bonus system of payment was used with negroes for drill runners and helpers, and Poles for other labor. Progress in March 1910 was at the rate of 390 feet per month.

TANAMI is the name of a new gold district now attracting attention and mentioned in our Melbourne letter this week. It is situated in the southwest part of the Northern Territory of Australia, a desert country in which prospecting has been carried on heretofore under great difficulties. The South Australian officials having found water by drilling and it having been discovered that the desert *spinifex* affords good pasturage, conditions have greatly improved. Gold has been found at a number of points and if adequate transportation can be afforded it seems probable that important mines will be developed. The building of the proposed transcontinental railway line is like to show that the interior of Australia is at least as capable of development as our own Great Basin region, and if the States can be brought to some agreement whereby the Federal Government can build the line great benefit will doubtless result.

NOMENCLATURE is ever a field for dispute but agreement as to definitions so markedly smooths the way of progress that earnest effort is commendable. In this issue Mr. R. P. McLaughlin challenges our use of 'dry hole' for a well in which oil was not found and argues that the term should be restricted to wells in which there is no water. He suggests 'non-productive' as proper for the first mentioned usage. Dryness is, of course, the antithesis of wetness and refers to the state of being covered with or permeated by a moist or fluid substance. In strict usage, therefore, a dry hole would be one in which neither water nor oil, nor indeed any fluid, had been found. Where drilling is commonly done for water the term is currently applied to wells in which there is no appreciable amount of water. Where, however, drilling is for oil, it is used universally, so far as we know, for wells in which no oil or only a trace is found. The oil men have also the expressive term 'duster' for such a well. For wells in which a small quantity of oil, but not enough for commercial purposes has been found, the term 'non-productive' is in general use throughout the Appalachian and Middle West fields. In California where many men new to the oil business have gone into it, and where water is much scarcer than farther east, there is some confusion in usage. Just as when in Australia sailors took to mining and gave the name 'reef' to what miners had long known as veins, lodes, or 'ledges' so in California men used to thinking of wells or holes in the ground for the obtaining of water see confusion in using 'dry hole' for a well from which large quantities of that fluid are flowing. The oil man sees no difficulty in this and cheerfully applies to such a well the term 'water hole', quite oblivions of the long established usage of that term on the plains and the desert for an open pool or spring. The ways of the reformer are beset with difficulties and none realizes that so keenly as he who would lead all men to exactness in the use of words. This is possible in a science and in scientific discussion. It is rarely accomplished in an art, and at present oil production is far from having reached a scientific basis.

Land Withdrawal Law

Congress finally passed an Act giving the President specific authority to withdraw land from entry for various 'conservation' purposes. The bill as passed is quoted in full in our Washington letter of this week. It is substantially as framed by the Senate and differs in several important particulars from the bill first passed by the House. The modifications bring it into essential harmony with the demands made by California oil men and for this they are largely indebted to the public opinion aroused by the address of Mr. Curtis H. Lindley at the Bar Association of San Francisco, April 29; an address already noticed in these columns. In general the retroactive features of the House bill have been omitted though at the same time strict definition is given of the sort of work which is to be taken as entitling a claimant to recognition when land is withdrawn. It is further provided that the Act is not to be construed as a 'recognition, abridgment, or enlargement' of any asserted rights in cases of oil lands on which claims had been initiated after any previous withdrawal. Ample provision has been made for protection of claimants where actual development is under way. The President promptly issued orders re-withdrawing the land under the new law so that the only cases remaining to be adjudicated are those in which there is doubt as to the 'diligence' with which work 'leading to discovery of gas and oil' has been prosecuted. Probably a retroactive clause would not have held as against actual development, certainly it should not have done so, and since other claimants are shut out by the new withdrawal order the law may well be considered a satisfactory compromise. There will remain a number of individual cases to be adjusted but these will be much less numerous than in case either the amendments proposed in the House had been adopted, or a general retroactive clause placed in the law.

The important thing to remember, and there seems to be some danger that it will be overlooked, is that all these withdrawals are expressly stated to be temporary. They are merely for the purpose of preserving the present status until a satisfactory law governing the disposition of the lands in question be enacted. It is also true that if the Western people, who have the larger experience with, and more direct interest in the matter, can agree upon a satisfactory code, there is little probability of Congress refusing to enact it. If some of the time and energy expended in fighting the withdrawals had been devoted to perfecting the land laws, real progress would have been made more rapidly. It is not good to keep the land

locked up for development; but it is equally bad that the old methods of disposition of the land should continue. It is violating no confidence to say that the attention of the Department of the Interior was first directed to the oil-land situation in California by the numerous attempts at fraud in locating such lands as agricultural, for gypsum, or under some other pretense. The plain truth is that the oil placer law is and has been all the time so inadequate as to invite fraud. It was to secure a better law, whether it provide for sale or lease, that the withdrawals were made. Later there has been some suggestion that a suitable fuel reserve for naval purposes be created, but for any such use wholesale withdrawals would not have been needed. The point to be remembered is that the quickest way to secure a vacation of the withdrawal order is to co-operate in the formulation of a really adequate law. Incidentally it, in connection with an honest administration of the present law, is the best means of forestalling additional withdrawals or any attempt to make them applicable to lands containing metalliferous ores.

Bureau of Mines and the Geological Survey

'Bunkoed' was the widespread comment through the West when it was announced that the President had appointed Mr. George Otis Smith to be Acting Director of the Bureau of Mines. The judgment is probably too harsh and yet, with the highest respect for the efficient Director of the Geological Survey, it seems to have basis. Mr. Smith has been connected so intimately with the movement to prevent appointment of Mr. J. A. Holmes and to secure the position for Mr. E. W. Parker, that this is apparently but an indirect way to secure that which we understand was impossible directly, through the threatened refusal of the Senate to confirm Mr. Parker's appointment. For the President, under these conditions, to wait until Congress adjourned and then appoint Mr. Smith, is bound to create a bad impression. All this is said without the slightest wish to question the personal fitness for the place of either Mr. Parker or Mr. Smith. Both are administrators of proved ability and gentlemen of large attainments and high character. The objection to putting the work into the charge of either is that they are not in sympathy with what the majority of those interested in creating the Bureau of Mines expect the latter to do, and what, so far as we are concerned, we believe to be the proper functions of the Bureau. The members of the Geological Survey for years have feared that a Bureau of Mines would come, in popular and Congressional estimation, to stand for the practical as against a supposed merely scientific interest in mining matters on the part of the Geological Survey, and that this would be reflected in the growth of the Bureau at the expense of the Survey. It is well known that for years Survey officials refused to have anything to do with the movement for a Bureau of Mines and that their final attitude was one of acquiescence rather than of aggressive helpfulness. In this they have been fortified by unwise statements on the part of some of the advocates of the new Bureau. It is not true and has not been, since the Geological Survey was created at least, that 'the mining industry is not represented at Washington' but the reiteration of that phrase seems to have got on the nerves of the gentlemen of the Survey until they have been fairly 'seeing things at night'. They should have more confidence in their work and in the discrimination of the mining engineers and mining men, on whose opinion in last analysis they must depend for support. No responsible mining man wants to take any proper function from the Geological Survey and all wish it many years of usefulness and appropriations many times compounded; but mining men as well as others reserve the right to ask for any needed additional representation at Washington and the further right of opinion as to how present representation shall be allotted. To pass over to the Geological Survey not only the interpretation of its own functions but that of other coordinate bureaus, is not fair to the latter, nor is it good administration. We fear that the Director of the Geological Survey has precipitated, what we are sure he was most anxious to avoid, a contest between the Survey and the Bureau of Mines. He may temporarily control the situation, but in the nature of things such a condition can not last and the reaction is likely to be more severe than would have been the original action had the latter been met helpfully rather than in a spirit of antagonism.

Research and Technical Men

Co-operation between the research men of the schools and technical men in charge of mining and metallurgical plants is much to be desired. In this issue Mr. R. C. Benner, of the department of chemistry of the University of Arizona, makes a plea for closer relations and suggests one plan by which they may be brought about. Occasionally the metallurgist and engineer in actual practice can take his problem to the university laboratory but oftener the exigencies of time and place intervene. At Golden, Colorado, Mr. Victor Alderson, president of the School of Mines, has been building up a testing plant with the avowed purpose of placing it at the disposal of all properly qualified engineers who may have tests to make or metallurgical problems to solve. He has taken the ground that one such plant can operate more economically and can with the same investment be made much more complete than if each engineer attempted to maintain his own. At the same time, as observers and assistants, the students will get the best possible training under the severe limitations of actual working conditions. It is too soon to pass final judgment on the project but certainly there is much to commend in it. Possibly the new Bureau of Mines may find a means of extending hospitality to engineers and their problems in cases where ordinary laboratories are clearly inadequate. If so it will serve a useful purpose and bind closer the ties between mining men and what is expected to become an exceedingly helpful Bureau. Mr. Benner's contribution is timely and all other suggestions as to means for bringing about what everyone wants, will be widely welcomed.

Mr. Roosevelt at Oxford

By T. A. Rickard

On Tuesday, June 7, Mr. Theodore Roosevelt delivered the Romanes lecture at Oxford University. It is an event so significant and so interesting as to warrant description even in a technical journal. I was privileged to be present and enjoyed the episode from the point of view of an Englishman in sympathy with American ideas.

A week earlier Mr. Roosevelt had received the freedom of the City of London and no sooner had he been made a burgess than he exercised the right of citizenship by offering counsel to the British administrators in Egypt. It was a magnificent indiscretion but a friendly act. After a year spent in Africa, in four spheres of British rule, he was well fitted to give both intelligent praise and salutary warning. He was as generous in emphasizing the beneficence of the work we are doing in the Sudan, East Africa, and Uganda, as he was outspoken in condemning the Egyptian nationalists who "treat assassination as a corner-stone of government" and the officials who are timorous in extinguishing violence, for "of all broken reeds, sentimentality is the most broken reed on which righteousness can lean." Fortunately his criticisms were well received. Englishmen have a sense of humor, not too evident, but it does save the day occasionally. Moreover, the administration of Egypt is now under the control of a Liberal government, hence the Conservatives, with their daily press and their social influence, were tickled to hear strictures upon the policy of their opponents and amused to see Roosevelt, under Providence, embarrass those in authority. If the Government of the day had been Tory, the speech at the Guildhall would have proved less palatable, for instance, at Oxford, where the Chancellor, Lord Curzon, was able to refer to it approvingly and even gleefully.

The American ex-President himself was amused at the sensation caused by his speech in the city and did not scruple to refer to the "engaging frankness" of it. This was at the luncheon given in his honor by the American Club just before the Romanes lecture. The Club is composed of Rhodes scholars and other American students in residence at Oxford. The chairman was F. P. Griffiths, who made an admirable speech, in the course of which he dropped the particularly apt remark: "Good sermons are rare." He referred, of course, to the lay sermons on sociology delivered by the guest of the occasion. Mr. Roosevelt does indeed sermonize, but with what tremendous effect! Ordinarily the sermon in church is delivered by a man whose opinion on the weather we would scarcely value, but the preaching of Roosevelt is that of a man who has done things, a governor of men, a hunter of lions, a foe of corruption, and a prophet of good.

He responded to the chairman's speech and to the enthusiastic welcome of those present by making a few happy observations, chiefly in appreciation of the Rhodes gift and the hospitality of Oxford to American students. He speaks with extreme slowness, and clearly; he has a good voice, tending to hoarseness; he is emphatic, with an accent that a Britisher calls American and a Bostonian would term Philadelphian. When speaking he has neither the cultivated ease nor the oratorial charm that mark the best American speakers, but the slowness and distinctness of his utterance are decidedly impressive as evincing deliberate thought and strong conviction.

The Romanes lecture was founded twenty years ago by J. G. Romanes, a biologist, who desired to see instituted at Oxford a lectureship similar in kind to that of the Rede foundation at Cambridge. The founder insisted that the lecturers should be selected irrespective of nationality, and that neither politics nor religion should be made part of the subject matter. The first lecture was delivered by Gladstone in 1892, the second by Huxley in 1893, the third by Weismann. Last year the lecturer was Arthur J. Balfour. An honorarium of £25 is paid to each lecturer. Gladstone modestly called his address 'An Academic Sketch' but it culminated in a magnificent burst of eloquence and concluded with the words that are near every Oxford man's heart: *Dominus illuminatio mea*. The 'Evolution and Ethics' of Huxley was one of his finest expositions of the development of civilization amid the welter of the struggle for existence and it illustrated the illuminating quality of a highly trained scientific imagination when applied to the profoundest problems of existence. In many ways this lecture was a superb preface to Roosevelt's, although it would be unfair to compare the latter's treatment of his subject with that of the greatest expositor of the nineteenth century. Yet Huxley would have appreciated Roosevelt, for he, too, had an intensely virile strain: intellectually he repeatedly proved the possession of an essential manliness, strong to meet the blows of fate and circumstance, and a self-mastery as striking, and far more touching, than that of the colonel of Rough Riders. The last words of the second Romanes lecture were curiously in accord with Rooseveltian sentiment, for Huxley said:

"We are grown men, and must play the man strong in will, To strive, to seek, to find, and not to yield,

> cherishing the good that falls in our way, and bearing the evil, in and around us, with stout hearts set on diminishing it. So far, we all may strive in one faith towards one hope:

It may be that the gulfs will wash us down,
It may be we shall touch the Happy Isles,
. . . . . but something ere the end,
Some work of noble note may yet be done."

Roosevelt at Oxford! The association of names provokes a contrast between the old and the new, between ideas and ideals so unlike that the difference excites humor, between the romantic and the practical, between thought and action. It was delicious to think of the Strenuous One lecturing the dons of the university, to hear the Rough Rider in the home of ecclesiastic romance, to see the ex-President of the United States facing the ex-Viceroy of India.

It happened to be a lovely summer day, smiling in sunshine, dropping the tear of a shower only to

freshen the wealth of flowers, shrubs, and trees that softens the architectural beauty of the long line of noble colleges. "Beautiful city! so venerable, so lovely, so unravaged by the fierce intellectual life of our century, so serene!" No wonder Matthew Arnold wrote rapturously concerning "the home of lost causes and forsaken beliefs, of unpopular names and impossible loyalties." Her ineffable charm is as potent, nay more, in this restless era of telegraphs and telephones, of motorists and airmen, than fifty years ago when Arnold thus apostrophised her. She still "whispers the last enchantments of the Middle Ages," but she is no longer withdrawn from the flowing river of the nation's intellectual life; on the contrary, to Oxford largely is given the task to train the rulers of empire. She may not be an incubator for engineers nor a nursery for financiers, but pre-eminently it is her task to train the men who become pro-consuls and administrators, the just and wise rulers over those alien races that live in peace under the British flag. Selborne, Milner, and Curzon typify the Oxford product. The noble traditions, the philosophic teaching, the aristocratic *milieu*, the historic associations, the reality of greatness, all afford fit environment wherein to teach young Englishmen to act worthily as the representatives of a dominant race when exercising imperial sway; but it may well be questioned whether Oxford affords the atmosphere in which to educate the leaders of a democracy, even under the shelter of a limited monarchy. Of social snobbery there is none worth mentioning, the students take rank on their merits as men, they work and they play under ideal conditions; the bank balance does not count; they discover that life is good if you know how to live it; they are happy! The learning is disinterested, for no commercial purpose is in view; the play is not made a business, it is just enjoyed for itself. Oxford is not a training-ship nor a hot-house, youth learns to live and to think there. Her windows are Gothic but through them is seen the wide world of today.

The Romanes lecture is always delivered in the Sheldonian theatre, which was the first public building designed by Sir Christopher Wren, the architect of St. Paul's cathedral. In this university theatre the Duke of Wellington was installed as Chancellor, amid great enthusiasm, in 1833; here Disraeli declared: "I prefer to be on the side of the Angels." Here, in the previous century, Handel conducted the performance of his oratorio 'Athalia'. It is not a large structure and it was full to overflowing long before the proceedings began. The audience numbered about four thousand. In the galleries were the undergraduates, in the side aisles were such of the general public as had been fortunate enough to secure tickets, and the floor of the theatre was wholly occupied by graduates, wearing gowns with their distinctive hoods; the white ermine of the Bachelor of Arts and the magenta satin of the Master of Arts. Facing the entrance was the 'throne' of the Chancellor and below him were two curving tiers of seats left vacant for the learned doctors who would come in procession escorting the distinguished man about to be numbered with them.

At three o'clock the academic procession entered. Through the window I could see them leave the School of Divinity, where they robed and where they had performed the formalities preliminary to conferring an honorary degree. They crossed the short space between the two buildings and entered the theatre, led by the marshal, followed by the bedels, with their rods of office, the Chancellor of the University (Lord Curzon of Kedleston), the Vice-Chancellor, the Heads of Colleges, and then a long line of doctors in scarlet hoods, among whom I recognized Andrew Lang and Rudyard Kipling. The two representatives of Oxford in Parliament (Sir William Anson and Lord Hugh Cecil) had already taken their seats. The train of the gorgeous robes worn by the Chancellor was borne by a younger son of the Earl of Selborne, recently High Commissioner in South Africa.

The audience being technically seated, although hundreds stood for lack of accommodation, the Chancellor addressed the Convocation in Latin, asking them if it were their pleasure that the honorary degree of Doctor of Civil Law be conferred on "the Honorable Theodore Roosevelt, ex-President of the United States of North America, and that the long-expected Romanes lecture may be delivered by him, etc." Cries of '*placet*' followed. Whereupon the bedels were sent to bring the honorable gentleman, and the Chancellor turned to the Vice-Chancellor and said, in Latin, what can be freely translated thus:

"Behold, Vice-Chancellor, the promised wight
Before whose coming comets turned to flight,
And all the startled mouths of sevenfold Nile took fright!"

The audience laughed appreciatively, and as Mr. Roosevelt entered a mighty burst of applause greeted him. Walking to the foot of the steps leading to the Chancellor's chair, he halted, and was addressed (still in Latin) by Henry Goudy, the Regius Professor of Civil Law. In a felicitous speech, heard only by those that were near, the orator referred to the principal events of Roosevelt's life, especially how "with unrivaled energy and tenacity of purpose he had combined lofty ideals with a sincere devotion to the practical needs not only of his fellow countrymen, but of humanity at large." This presentation speech being ended, the Chancellor spoke; and at the first word there was a roar of laughter, for he said: "*Strenuissime, insignissime civium toto urbe terrae hodie agentium.*" And the Most Strenuous One enjoyed it, as he did the references that followed, especially the "*hominum domitor, beluarum ubique vastator.*" This short speech ended with the words that conferred the degree. The recipient allowed himself to be robed in a scarlet gown, and then shook hands with the Chancellor. The latter directed the bedels to conduct "the honorable Doctor to the lectern," whereupon Roosevelt, amid further applause, took his place, ready to begin the lecture.

Before he began, however, he had to listen to another speech, this time in English, by the Chancellor. Lord Curzon, a tall and imposing figure in gorgeous gilded robes, stood facing him. It was worth coming a long way to see these two men *vis à vis*, each playing a great part in an impressive performance.

Curzon spoke exeellently, in cultivated aeeents, easily, with a toueh of humor, an obvious friendliness, and with the superb eonfidenee of a praetised speaker addressing a ehosen audienee. The nobleman, the statesman, the ex-Vieeroy of India paid his eompliments to the eitizen, the leader of the greatest democracy in history, the ex-President of the United States, and it must be eonfessed that the phrasing was worthy of both men. It thrilled me through and through that so fine an appreeiation eould be uttered, and yet be true. The Chaneellor said that he had just had the pleasure of addressing Mr. Roosevelt in a language whieh, of eourse, he would reeognize as the habitual medium of intellectual intereourse in the university to whieh they now both belonged. It now fell to him to say a few words of weleome to Dr. Roosevelt, in a language of whieh in its most pieturesque and foreible idioms he was an aeknowledged master. The invitation to deliver the Romanes leeture had served as a nueleus around whieh had been built "that wonderful progress of his through the eountries of Europe, a triumphal progress sueh as had been enjoyed but by few even among eonquerors and kings." He then went on to say: "And yet I doubt whether in all the eountries he has visited Mr. Roosevelt has anywhere reeeived a warmer weleome than that whieh has been given him in this aneient seat of learning, for we greet him not merely as a great ruler of men, the most eonspieuous figure in Ameriea's history sinee Abraham Lineoln, not simply as a sineere and outspoken friend of his eountry, though from all his utteranees we knew that he was, but also as a student of many forms of knowledge, a writer of books, a fearless preaeher of robust and manly faith, a relentless foe of eonventions and shams, and, above all things, in all that he says and does he is what Browning said of Clive, 'pre-eminently a man'."

It may be that the Chaneellor was a trifle too faeetious; at least some of the audienee thought so, but I eonfess to having enjoyed his witty touehes, because they gave relief to the general tone of handsome eulogy. It was a delightful speeeh, delivered perfeetly.

All the while the subjeet of it stood quietly at the leetern, with his sheets of manuseript ready to read. An astonishingly young-looking man, not within ten years of his real age. A head eovered with short thiek ruddy brown hair and a stalwart figure, he looked anything but academie. The baek of his head seemed that of a man in the thirties and belligerent in every line of it; not domed, but flat on top; it bespoke aetion rather than eontemplation. Obviously he was in splendid health and brim-full of vitality. When Gladstone delivered the Romanes leeture he was 83. Huxley was 68, Roosevelt was 52. Sueh physieal well-being is a great faetor in the eareer of a political reformer. Roosevelt is pre-eminently the eupeptie hero of our day: May he outlive all his enemies.

When he began to deliver the leeture his aeeent was strongly marked. Perhaps a toueh of nervousness affeeted his enuneiation; as he proeeeded this defeet was less evident, although in some words the pronuneiation was persistently provineial, by which I mean that he did not speak the English language as it is spoken by the most eultivated Amerieans, for instanee, at his alma mater, Harvard. Whether life in the West or assoeiation with politieians in the East of America be the eause, the fact remains that Mr. Roosevelt speaks English with an aeeent no purer that that of many Britishers. However, this detail is not material. It was lost in the broad effeet.

The subjeet was 'Biologieal Analogies in History'. He began with a graeeful eompliment to loeal assoeiations and to memories that "are living realities in the minds of seores of thousands of men who have never seen" Oxford. Sueh assoeiations, he said, "are no stronger in the men of English stoek than in those who are not. My people have been for eight generations in Ameriea, but in one thing I am like the Amerieans of tomorrow rather than like the Amerieans of today, for I have in my veins the blood of men who eame from many different European raees." This referenee to his own "ethnie make-up" and to that of his fellow eountrymen was apt and enabled him to emphasize an understanding sympathy superior to biologieal anteeedents. Loud applause puneetuated the statement that ended the introduetion when he said: "Common heirship in the things of the spirit makes a eloser bond than common heirship in the things of the body."

Next he diseoursed on the study of history, laying stress on the neeessity for treating sueh a study not only as seienee but as literature. "We need a literature of seienee that shall not only be read but shall be readable." Many of those present must have thought of the great biologist who delivered the seeond Romanes leeture and who in the work of his life illustrated to perfeetion the applieation of literary treatment to seientifie knowledge. I wondered why Roosevelt omitted the ehanee to refer to Huxley. He proeeeded to point out that the proper study of mankind is man in a biologieal sense and that the historian must avail himself of "the seienee of evolution, whieh is inseparably eonneeted with the great name of Darwin." He eonfessed himself as impressed by the parallelism between the eyeles of animal life and those of national life. But not without a warning against false analogies. "As knowledge inereases our wisdom is often turned into foolishness." Terms must be defined lest we fall into the error of hasty generalization. We talk of a "new speeies", yet no living thing ean really belong to a new speeies. Similarly, the "extinetion of speeies" may mean either of two things: that the speeies has literally died out; or that it has so ehanged as to be no longer reeognizable.

Then followed a sketeh of the biologieal history of South Ameriea. As soon as the southern eontinent beeame joined, by the elevation of the isthmus, with the northern regions, the animals of North Ameriea passed over the land bridge and invaded South America. A riot of life ensued. The eonquering type developed enormous bulk and eomplete armor proteetion. The indigenous ereatures that survived also grew in size and power aeeording to their needs. Events sueh as these are matched in the history of man. Nations go under and disappear; others

survive and are regenerated into a 'new' nation, in which the remnants of the old are perpetuated.

In this first portion of his address Mr. Roosevelt discussed fundamental biological principles without saying anything new. Remembering Huxley's lecture on 'Evolution and Ethics', remembering that in biology Roosevelt was the veriest amateur, I felt that he was on the edge of a fiasco, and the feeling oppressed me keenly. But when he got off this treacherous ground and began to touch on matters in which he could show clearer insight, I realized that the early part of the lecture laid the foundation for what was to follow. He drew analogies between the fate befalling the forms of animal life and the destiny of the great artificial civilization, such as Babylon and Nineveh, Greece and Rome. "The growth of soft luxury, after it has reached a certain point, becomes a national danger patent to all. If the homely commonplace virtues die out, if strength of character vanishes in graceful self-indulgence, then the nation has lost what no material prosperity can offset." There he struck a characteristic chord. Holland furnished another example. "Her fatal weakness was that so common in rich peace-loving societies, where men hate to think of war as possible, and try to justify their own reluctance to face it either by high-sounding moral platitudes or else by a philosophy of short-sighted materialism." But Holland and Italy taught us how races that fall may rise again. "When the Roman Empire went down in ruin, it was one of the greatest cataclysms of history, but it was not all mere destruction. Not only did Rome leave a vast heritage of language, culture, law, ideas to all the modern world, but the people of Italy kept the old blood as the chief strain in their veins. In a few centuries came a wonderful new birth of Italy." Italy rose and fell again, more than once. Spain and Portugal also had their day. "Their flowering time was as brief as it was wonderful. When the first brilliant period of the leadership of the Iberian peoples was drawing to a close, at the other end of Europe, in the land of the melancholy steppe and forest, the Slav turned in his troubled sleep and stretched out his hand to grasp dominion."

The memories of men are short and the supremacy of races is brief. "More than a century passed after the voyages of Columbus before the mastery of war began to pass from the Asiatic to the European." Then "the European advance gathered momentum, until at the present time peoples of European blood hold dominion over all America and Australia and the islands of the sea, over most of Africa, and the major half of Asia." The various nations of Europe in turn sought "a place in the movement of expansion, but for the last three centuries the great phenomenon of mankind has been the growth of the English-speaking peoples and their spread over the world's waste spaces."

Here he entered the third phase of the lecture; he now held the sympathy of his audience and frequent applause punctuated his speech. Unfortunately so much time had been given to the preliminaries and to his own introductory observations that, realizing the inadequacy of time, he began to discard sheets of typewritten manuscript without reading them. As the newspapers had received advance copies of the lecture several weeks earlier, the reporters had an easy task and the frequent rustling of leaves as they followed his utterances indicated the omission of long paragraphs. Another result followed, for the evening papers, and even some of those appearing next morning, quoted portions of the lecture omitted by the lecturer and offered comment on matters of which he had not spoken. He held the sheets in his left hand and used his right for an occasional gesture, raising his hand with the index finger erect to emphasize a point. But there were not oratorical flourishes; he spoke as a man careless of everything except the desire to convince.

Thus he came to the comparison between Britain and Rome, and between the British empire and the American democracy. "England has peopled continents with her children, has swayed the destinies of teeming myriads of alien races, has ruled ancient monarchies, and wrested from all comers the right to the world's waste spaces, while at home she has held her own before nations each of military power comparable to Rome at her zenith." Rome fell by attack from without, because of domestic ills. He pushed the analogy: "We should be vigilant against foes from without, yet we need never really fear them so long as we safeguard ourselves against the enemies within our own households; and those enemies are our own passions and follies." Americans and Englishmen alike must keep in mind that the success of a great democracy depends on self-knowledge and self-mastery. "In the last analysis the all-important factor in national greatness is national character." What was to be our destiny? Were we as nations soon "to come under the rule of that great law of death which is itself but part of the law of life." None could tell. The growth of luxury, the love of ease, the taste for vapid and frivolous excitement were both evident and unhealthy. The ominous sign was the decline in the birth-rate. But "no man is more apt to be mistaken than the prophet of evil." It was "strange indeed to look back at Carlyle's prophecies, and then think of the teeming life of achievement, the life of conquest of every kind, and of noble effort crowned by success which has been ours for the two generations since Carlyle complained to High Heaven that all the tales had been told and all the songs sung, and that all the deeds really worth doing had been done." Come what might we belonged to people "who have not yielded to the craven fear of being great." Moreover, while freely admitting all the follies and weaknesses of our day, it is yet mere perversity to refuse to realize the incredible advance that has been made in ethical standards. He was no pessimist. He had scant patience with "the silly cynicism which insisted that kindliness of character only accompanies weakness of character." On the contrary, he held that "rugged strength and courage would go hand in hand with a lofty scorn of doing wrong to others." Each nation had problems of its own and must solve them in its own fashion, in a spirit of broad humanity, free from weakness and sentimentality. "As in war to pardon the coward

was to do cruel wrong to the brave man whose life his cowardice jeopardized, so in civil affairs it was revolting to every principle of justice to give to the lazy, the vicious, or even the feeble or dull-witted, a reward which was really the robbery of what braver, wiser, abler men had earned." In dealing with social problems "the one prime necessity was to remember that though hardness of heart is a great evil, it is no greater an evil than softness of head." Each man was entitled to be treated on his worth as a man. "To more than such just treatment no man is entitled, and less than such just treatment no man should receive." Thus he harped on that noble string from which the American makes the sweetest music known to humanity.

He spoke at length in this strain and I select from his concluding remarks the following sentences: "The only effective way to help any man is to help him to help himself; and the worst lesson to teach him is that he can be permanently helped at the expense of some one else. True liberty shows itself to best advantage in protecting the rights of others, and especially of minorities. Privilege should not be tolerated because it is to the advantage of a minority; nor yet because it is to the advantage of a majority. No doctrinaire theories of vested rights or freedom of contract can stand in the way of cutting out abuses from the body politic. Just as little can we afford to follow the doctrinaires of an impossible—and incidentally of a highly undesirable—social revolution, which in destroying individual rights—including property rights—and the family would destroy the two chief agents in the advance of mankind, and the two chief reasons why either the advance or the preservation of mankind is worth while."

When he finished, the theatre resounded with hearty applause. The audience had listened with the closest attention; contrary to precedent, even the undergraduates in the gallery had forborn to chaff; it was evident that the academic gathering was deeply touched, sympathetically appreciative, and finally heartily enthusiastic. In its strong points, as in its weak ones; in its general tone of outspoken virility, unsophisticated reasoning, and cheerful optimism, the lecture was representative of the lay sermonizing for which the lecturer is now famous. He spoke as one who reads the classics in the intervals of lion-hunting, and studies history while fighting monopolies. He is as downright as he is upright, as broad in his ideas as he is deep in his convictions. It may be that his sayings do no apply the stimulus of novelty to a cultivated mind, but the same may be said of many lectures delivered at Oxford, and elsewhere. He makes plain things obvious and gives a new life to platitudes. He dresses the eternal verities in the garments of his own manly sincerity so that they seem endowed with the freshness of a new day instead of the staleness of forgotten ideas. He came to Oxford a man on horseback, a Rough Rider in a cathedral, a practical man among scholars, a radical among reactionaries, but he left it vibrating to the glad optimism, sound common-sense, and inspiring invocation of his thoughtful utterances. He forged another golden link between the two English-speaking peoples and proved indeed that "common heirship in the things of the spirit makes a closer bond than common heirship in the things of the body."

PACIFIC NORTHWEST SOCIETY OF ENGINEERS

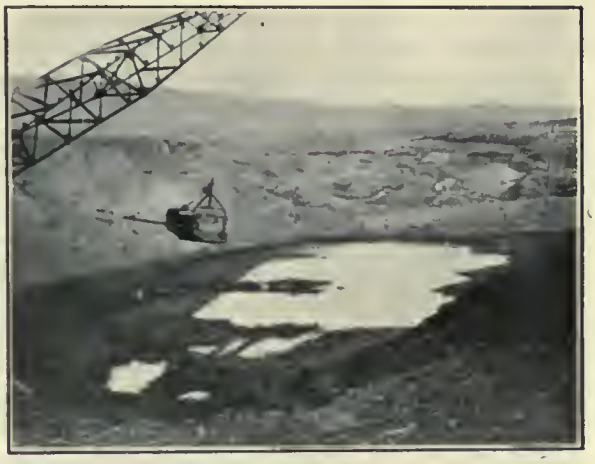
The eighth annual convention of this society was opened in Seattle, Washington, on Thursday morning, June 16. The business included the annual address by the president, H. Day Hanford; a paper by C. C. Ward, City Engineer, Wenatchee, Washington, on 'Irrigation Development in Wenatchee Valley'; one by Major C. W. Kutz, U. S. Engineer, on 'Seacoast Defences'; and a full discussion of the proposed law providing for licensing engineers practicing in the State of Washington. The committee in charge of the last-mentioned subject, with Capt. A. O. Powell as chairman, was continued, with instructions to report progress in September; also to take up the subject of water rights and conservation in Washington. On Friday morning an excursion was made by steamer to Irondale, near Port Townsend, Puget Sound, to inspect the iron and steel-making plant of the Western Steel Corporation, at which in May the manufacture of steel was begun, using pig iron from China, scrap iron, and local iron ores. In the afternoon Fort Worden was visited, and there the working of the torpedo-firing plant and submarine mines was explained, and target practice with 12-in. mortars and 6-in. guns was witnessed.

The Shannon Copper Co., through an agreement with the railroads, of which the Interstate Commerce Commission has approved, has obtained a reduced rate on all its supplies, such as coke, oil, and lumber, which will effect a saving to the company of from $35,000 to $40,000 per annum. This new rate is to take effect immediately. A saving is also being made of about $5000 per month through the operation of the new Shannon-Arizona railroad, which carries the Shannon ores to the smelter at Clifton. A profit of $8000 or $10,000 a year is also expected from the company's new water system. The importance of these items, totaling around $100,000 per year, will be better appreciated when it is remembered that Shannon's total earnings for the year ended August 31, 1909, were $84,000. In other words, Shannon is making a saving through new operating economies recently carried into effect which should more than duplicate the profits for the last fiscal year. The full effect of these economies will not be reflected in the earnings for the present fiscal year, but they will be an important factor. Shannon is producing about 17,000,000 lb. of copper per annum and at a lower cost than ever before. The company has recently opened some high-grade orebodies on the lower levels, where active mining will soon commence.—*Boston News Bureau.*

In high-voltage transmission lines the standard practice is to erect seven or eight towers per mile at an approximate cost of $500 per tower. This includes material and construction, but does not take into consideration right of way and wires.

Bucket Scraper for Use in Placer Mining

The accompanying pictures illustrate the work of a bucket scraper used by C. W. Purington at the Kolchan mines in East Siberia. The pictures tell the tale so well that few words are needed. The machine is capable of digging a pit 120 ft. wide and 27 deep. It handled 1700 cu. yd. per day when working full time, and made an actual average of 593 yd. for 59 days including all stops. The material handled was old tailing which was delivered to a sluice supplied with water by means of centrifugal pumps. The dirt makes its own hopper and the whole arrangement is very simple and flexible. Operating costs under the adverse condition obtaining at Kolchan were about 30c. per yd. This included the high wages of an engineer and mechanic taken from Chicago to erect and start the machine. The advantages of the bucket scraper are that it permits preliminary work at low first cost in out of the way places long before a dredge could be installed or even before sufficient data would be available to warrant building a dredge. In this case the machine was bought in Chicago in April and enough dirt was handled to show a profit on the season's work before October. This year it is to be used in connection with a scow carrying the gold-saving tables usually placed on a dredge.



The Beginning of the Use of Natural Gas for Fuel

By John L. Cowan

It is said that J. M. Guffey, the Pittsburg oil operator, expended more than a million dollars in vain endeavors to develop in California an adequate supply of natural gas to justify the application of this ideal fuel to manufacturing purposes on a large scale. His repeated failures, and the nature of the formations found in the majority of his numberless test wells, convinced him that the overlying strata, above the oil and gas sands, were not sufficiently compact to retain so volatile a medium, at high pressure. Consequently, it has long been regarded as settled that California would never have gasfields at all comparable with those of Pennsylvania, West Virginia, and Indiana. However, the great gas wells recently struck in the Buena Vista hills, in the Bakersfield district, have changed the natural-gas situation and outlook. One of these wells is estimated to be producing at the rate of 11,000,000 cu. ft. of gas per day, and another is said to produce 16,000,000. Granting that these estimates are exaggerated, it is certain that both are great wells; and that further exploration will result in the finding of many more as large or larger is probable. In the Pittsburg manufacturing district, gas is piped for hundreds of miles, so that the development of an important natural-gas field in the Bakersfield district would almost certainly result in the laying of pipe-lines to San Francisco. What this would mean to the manufacturing industries of the Bay cities, and, in fact, of the whole State, is easily seen. There is no manufacturing purpose for which this fuel is not superior to coal, oil, or any other fuel known. The possibility, then, that the ideal fuel may soon cut an important figure in the industrial development of the Pacific Coast appears to give a timely interest to some ancient but little known history.

Like many other good things, natural gas, although known for centuries, was first turned to practical account in the United States. The Chinese claim to have conveyed it through bamboo pipes and to have used it for heating and lighting thousands of years ago. The Parsees or Fire-worshippers, burned it in their temple at Baku, and regarded it as an everlasting miracle attesting the truth of their religion. And it is believed by many modern investigators that the tripod of the Delphic oracle was placed over a vent or fissure, from which issued natural gas, the fumes of which caused the mysterious 'frenzy' of the oracle, giving solemnity and an appearance of supernatural influence to the ambiguous utterances of the most famous soothsayer of all time. In spite of these ancient uses or misuses, it must be admitted that natural gas remained little more than a curiosity until in comparatively recent years, and that its value was first appreciated and an intelligent search first made for commercially important supplies in our own country. As was the case with petroleum, West Virginia and Pennsylvania share the honors of discovery and utillzation.

One of the earliest notices of the existence of natural gas in America comes from General Washington. In 1775, he visited a 'burning spring' on the Great Kanawaha river, nine miles above Charleston. The spring was simply a hole in the ground, which was generally partly filled with surface water, draining in after rains. Through the water, gas forced its way, keeping it in constant ebullition as if boiling. When ignited the gas blazed up to a height of several feet. The land on which the spring was located was pre-empted by Washington, along with other tracts given him by the colony of Virginia in return for military services. In his will he bequeathed one acre of land, with this burning spring in the centre, to the public forever, making the following reference to its acquisition: "The tract, of which the 123 acres is a moiety, was taken up by Gen. Andrew Lewis and myself for and on account of a bituminous spring which it contains, of so inflammable a nature as to burst forth as freely as spirits, and is nearly as difficult to extinguish." This burning spring was for many years regarded as one of the greatest natural wonders of the country. People traveled miles to visit it, and scientists of that day indulged in much learned speculation and discussion as to the origin of the escaping gas.

Similar phenomena were later discovered near the Little Kanawha river, and attracted an equal amount of attention. Forty-one miles above the mouth of the river is a little creek, known as 'Burning Spring creek'. Half a mile from the point where the creek flows into the river were the two springs that gave it name. From one of these, known as the Big Spring, the gas emerged in such quantities that, when set on fire, the flames covered an area of eight or ten square feet, and blazed up to a height of five or six feet. When ignited this spring would burn for months, until extinguished by a storm or wind of unusual severity. Similar burning springs were discovered from time to time in various parts of Western Virginia and Pennsylvania, and one near Niagara Falls, in New York. However, these were simply curiosities and objects of wonder. The first discovery of gas in sufficient quantities to tempt men to try to put it to use was purely an accident, incidental to the drilling of a salt well.

In 1815 a salt well was put down by Capt. James Wilson, within the present city limits of Charleston, West Virginia. The Captain was disappointed in both the quality and the quantity of the brine secured, and declared that he would get more and better salt water, or bore the well clear down to h—l. Shortly after this profane declaration, the drillers encountered a heavy flow of salt water and gas—the first natural gas ever struck in a well drilled by human agency. The gas caught fire and burned to a great height, to the great alarm and consternation of everyone in the neighborhood. Possibly thinking that he had certainly reached the destination announced, the doughty captain drilled no deeper, abandoning the well as worthless. This first of all gas wells was situated on land now included in a lease of the Charleston Gas Light Co. This was by no means the only salt well in the Kanawha valley in which gas was struck. In fact there were scores

of them; but not until 1843 does it appear to have occurred to anyone to put it to work. In that year William Tompkins put down a salt well a short distance above Washington's burning spring, and secured a large flow of salt water accompanied by gas. The gas was confined by means of an inverted kettle, piped off to the furnace, and employed for boiling the brine, effecting a great saving in both fuel and labor. Two years later, Dickson and Shrewsbury put down a well a short distance from the one belonging to Tompkins, tapping at a depth of about 1000 ft. the great gas reservoir of West Virginia, which is today so important a factor in promoting the industrial greatness of the Pittsburg manufacturing district. So great was the pressure that the tools, weighing about 1000 lb., were shot up from the well, followed by a column of salt water reported to be fully 150 ft. high. The roaring of the gas could be heard for miles. No doubt this well was small in comparison with some of the deep-sand 'gassers' of later days; but nothing like it had ever before been known in the world's history. It is, therefore, not strange that it created a profound impression, giving an idea of unseen forces of nature, and formerly undreamed of possibilities beneath the crust of this solid old earth.

The great gas well blowing a huge column of salt water high into the air was considered worth traveling long distances to see. A stage route passed near by, and it was the custom of the drivers to stop their teams and permit passengers to view the wonderful display. An amusing incident is related in this connection, by J. P. Hale, formerly president of the West Virginia Historical Society. He tells that a Harvard college professor was once traveling over this stage route; and, being of an investigating turn of mind, anxious to contribute his mite to the sum total of scientific knowledge, he went close up to the well and struck a light, to see whether the current report that the stuff would burn was true or not. It is unnecessary to say that the professor's doubts were quickly settled. It burned! The woodwork about the well was destroyed; the professor's hair and clothing were set on fire, and he only saved himself from cremation by jumping into the river. He was then taken to Charleston, where he was placed in the care of a physician for repairs.

The fire was finally extinguished, and the gas and salt water conveyed through pipes to the furnaces, where both were utilized. For a number of years the natural pressure of the gas lifted the salt water to the top of the well, forced it more than a mile through pipes to the salt furnaces, boiled the brine in the kettles, and supplied heat and light for the entire plant. I cannot help thinking that one of the owners was a little hard to please, when he remarked that the arrangement would be perfect if only the gas could be made to lift the salt from the kettles and pack it in barrels. The remarkable success of this well induced many other salt manufacturers of the Kanawha valley to drill deep wells in search of gas; and prior to the year 1850 Worth & English, Tompkins, Welsh & Co., William D. Shrewsbury, J. H. Fry, J. S. O. Brooks, and a number of others were using this fuel exclusively in salt manufacture.

The first use of natural gas for heating and lighting of buildings appears to have been made at Fredonia, New York. In 1821 it was discovered that gas was escaping from a spring near the town, and it was piped to a mill and several stores, which it supplied with light. It was also introduced into the public buildings, and was considered a wonder of sufficient importance to be shown to General Lafayette, when he passed through the village in 1824. A few years later a shaft was dug, and enough gas secured to supply 30 burners. In 1858 another shaft was sunk and two wells were drilled, one to a depth of 150 ft., securing a total supply of 2000 cu. ft. per day, which was consumed in the village, mainly for lighting purposes. The first general application of gas to domestic purposes, including cooking, lighting and heating, was in the Pennsylvania oil fields. After the oil excitement attained considerable proportions, many drillers and pumpers made a practice of piping the escaping gas to their shanties, and using it for cooking their victuals and lighting their rooms. The first town to be piped and to make general use of this fuel was Fairview, in Butler county, Pennsylvania, in the year 1870. The experiment proved so successful that Fairview's example was soon followed by Petrolia, Karns City, Argyle, and Parker City, all in the great oil belt of Western Pennsylvania.

It was later, in 1870 or 1871, that the new fuel was first used in iron manufacture at the iron works of the Great Western Iron Co. (of which Samuel J. Tilden was one of the principal owners), at Brody's Bend, on the Allegheny river; and shortly thereafter in the iron works at Leechburg. From that time forward its use became general, wherever the oil operator happened to find gas. However, it was not until in 1884 that the gas industry proper can be said to have come into existence with the laying of pipe-lines into Pittsburg. By 1885 the Consolidated Fuel Gas Co., and the Penn Fuel Co., were delivering from the Murrysville field about 10,000,000 cu. ft. of gas per day in Pittsburg. The Washington Gas Co. had laid a line 20 miles long from the famous McGuigan well in Washington county; and the Philadelphia Company had begun the construction of its first three big lines, one from Murraysville, one from Tarentum, and one from the Homewood wells. All these seemed like great developments, in those days, but they now appear small and insignificant. Many gas companies have main lines hundreds of miles in length, with smaller branches and feeders aggregating thousands of miles long, great pumping stations for forcing the gas long distances, field forces of thousands of men, leases covering hundreds of thousands of acres, and thousands of producing gas wells. Tens of thousands of families use gas exclusively for all domestic purposes, and scores of iron and steel, glass, stoneware, clayworking, and other manufacturing plants depend upon it for all industrial uses. Whether these enormous developments will ever be remotely approximated in California remains to be seen. The situation in California today, however, is practically the same as it was in Pennslyvania in the early eighties, when the Murraysville gas field first began to attract the attention of capitalists.

Faulting in the Bullfrog District, Nevada

By W. H. Emmons and G. H. Garrey

*In the Bullfrog district the tilting of the lavas occurred before or after they were faulted, or else the two processes went on together. Tilting before faulting is represented diagrammatically by Fig. 4; where an originally horizontal flow *ab* is tilted through 27° to *ad* and then faulted to *cd*. If it is assumed that tilting occurred before faulting, then rhyolite No. 7 (along the plane of section shown in Fig. 3) after tilting should have been 13,000 ft. lower at the east end of the 33,600-ft. section of rhyolite No. 7 than the same bed was at the west end. If the period between the deformation by the two processes were long enough for any considerable erosion, evidence of such relief should be preserved in this or adjacent districts in the form of a thick accumulation of derived sediments. These sedimentary rocks would now be faulted but not tilted. There is, of course, the possibility that nearly horizontal faulted sedimentary rocks of later age than the lavas do occur below the desert flats and that beds of the same age have been eroded from the higher country; but if all of the faulting had followed all of the tilting, with erosion and deposition between, the chances would have been good for the preservation of remnants of horizontal sedimentary beds, since faulting alone has caused displacement of more than a mile and without active simultaneous erosion must have produced that much relief. The absence of faulted but untilted rocks of later age than the lavas points toward the conclusion that the lavas were not tilted very long before they were faulted.

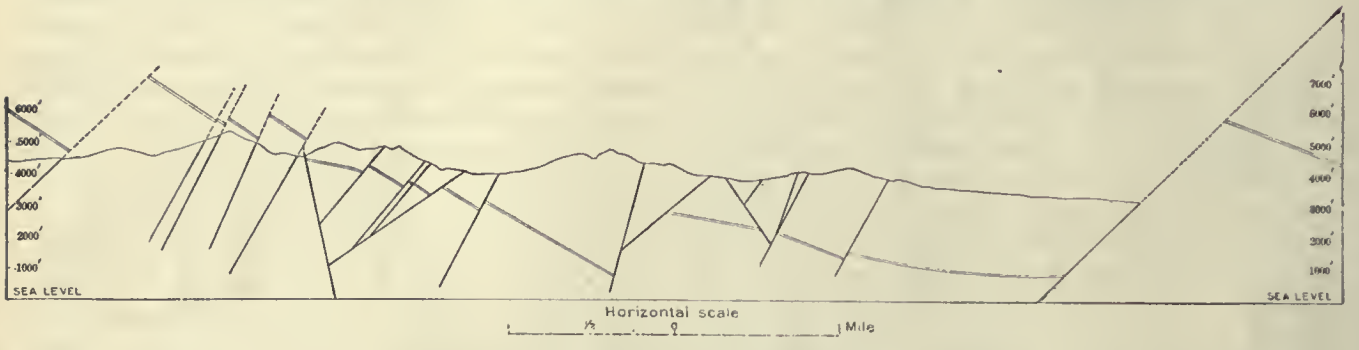


Fig. 3. Diagram illustrating displacement by fault lines at Bullfrog.

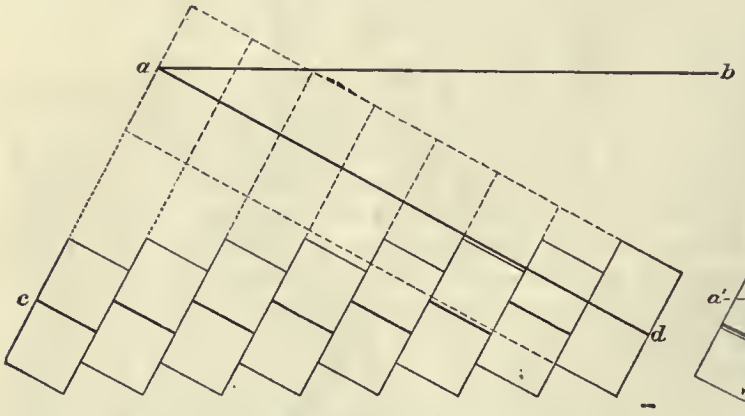

Fig. 4. Diagram illustrating tilting before faulting; vertical section at right angles to the strike of the faults. The original horizontal flow *ab* is tilted to *ad* and then faulted to *cd*.

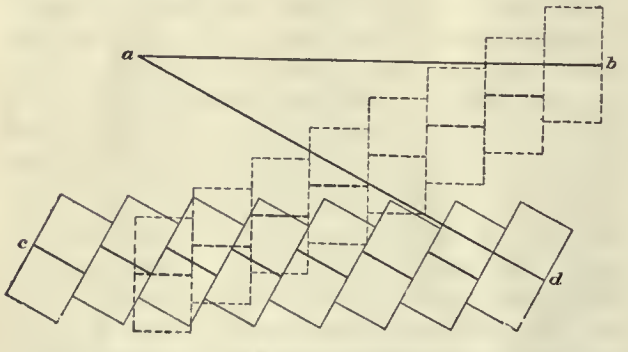

Fig. 5. Diagram illustrating faulting before tilting; vertical section at right angles to the strike of the faults. The original flow is faulted with downthrow to the left and the series of blocks as a whole is then tilted to the position *cd*.

Faulting before tilting is represented diagrammatically in Fig. 5, where the bed *ab* is faulted with downthrow to the west, the segments taking the position shown by the dotted lines. If the series is tilted 27° with *b* as an axis, these blocks take the position of the solid lines. If all of the tilting shown in Fig. 3 had occurred after all of the displacement by faulting, then there should have been a very great relief before tilting, for faulting, as expressed in this

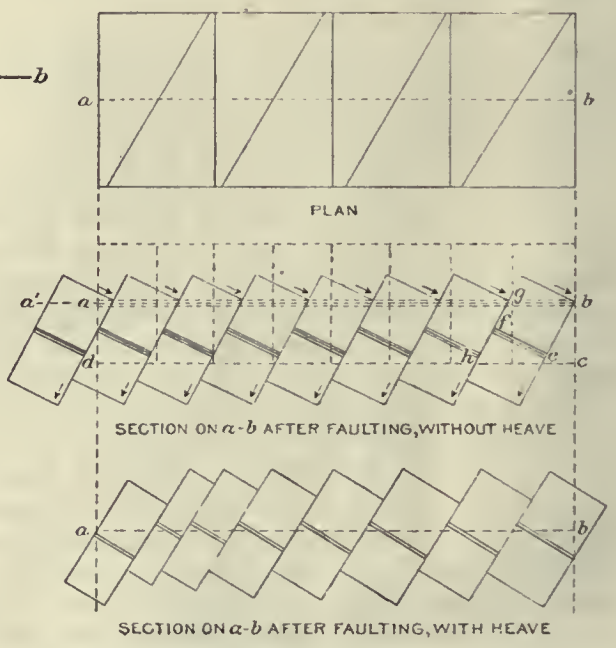

Fig. 6. Diagram illustrating simultaneous faulting and tilting. See text for explanation.

*Abstract from Bull. 407, U. S. Geol. Survey. Continued from Mining and Scientific Press, p. 931, June 25.

section, depressed the rocks 11,250 ft. If erosion had taken place between the operation of the two processes, unless it were vigorous enough to carry all of the detrital material entirely beyond the area examined, the débris should now form tilted sedimentary rocks, not faulted, and some remnants of such rocks would very probably remain at some place within or near the area. Although at many places the beds on different sides of a fault dip at different angles, there is very little variation of dip within single blocks. This fact further suggests the interdependence and contemporaneity of the faulting and tilting. The short geologic time which has elapsed since the beginning of the deformation of the lavas by faulting and tilting suggests further that the two processes were nearly if not quite contemporaneous.

If faulting and tilting went on together, the effect would be that of rotation, each block moving more or less independently of adjoining blocks. Such movement is represented diagrammatically in Fig. 6, where the flow *ab* is cut by regularly spaced vertical fissures and the blocks are rotated independently without any tilting of the mass as a whole. As shown in this figure the horizontal distance through the blocks along the line *a'–b* is about 12% greater after rotation than before, and in consequence the area of the horizontal section through *a'–b* is likewise increased 12%, providing the width of the faulted area remains the same. If rotation occurred without extension along the line *a'–b* then there must have been a great horizontal movement or heave of the blocks along the fault planes while they were faulting. As shown in plan in the upper portion of this diagram, the faults cross one another, making angles of about 35°. This forms wedges, some of which present sharp edges to the plane of the section. If during deformation some of these wedges moved broad-part forward (at right angles to the line of the section) there would be room for the remaining blocks to settle without such great extension along the plane of the section. This horizontal element of movement along the faults of the Bullfrog district is recorded by inclined striae on fault planes.

The striations on the slickensided surfaces of the faults in the Bullfrog area make angles that vary from a fraction of a degree to 90° and have an average pitch of about 60°. Consequently the movement must have had a considerable horizontal component. Observations of recent faulting in California show that horizontal movement may be very important and that in some cases there seems to have been little vertical movement. Fig. 7 shows beds that have been tilted and that are cut by a fissure of which the dip is opposed to that of the beds. The strike of the fissure makes an acute angle with the strike of the beds. The left half of the block is shown to move horizontally toward the reader. This results in an apparent normal displacement that, when seen only in cross section, appears to have been straight up or down the plane of the fault. This effect is not produced when the beds are flat or when the strike of the fault is parallel to the strike of the beds, provided the movement is entirely horizontal; but the vertical displacement and horizontal displacement increase as the angle between the strike of the fault and the strike of the beds increases and are greatest when this angle is 90°. As shown in Fig. 7, there is, after faulting, an overlap of strata in the plan and a gap in cross section. If the left half, on the other hand, had moved in a horizontal direction away from the reader (see Fig. 8), the result would be an apparent reverse fault, or one in which the foot-wall appears to have dropped with respect to the hanging wall. There is a gap in plan and an overlap in vertical section. With sufficient horizontal movement in the proper direction, such an apparent reverse fault might result even when some of the movement of the hanging wall was down the dip of the fault plane.

A study of the Bullfrog area shows that most of the offsets of strata due to faulting are such as could be produced by movement of the hanging wall side down the dip, without horizontal displacement, or heave. But nearly everywhere there is an offset with an overlap instead of a gap. This shows that the horizontal element of movement of the blocks, however great it may have been, was in the direction which increased the apparent vertical displacement, or else its offsetting effect on the tilted beds was less than that caused by vertical movement, for if it had been greater and in an opposite direction a gap would have resulted where the relations of beds to fault planes are like those shown in Fig. 8, and the fault, as shown in vertical sections, would have been reverse. Since in the Bullfrog district no clearly reverse faults are shown and since there are no gaps on the surface such as would indicate them, it seems very probable that forces causing horizontal movement always operated in one direction, and so as to increase the apparent displacement. As already stated the directions of striae observed, taken all together, show that, in the movement recorded, the vertical component was greater than the horizontal component.

It is generally recognized that crustal shortening accompanies folding of strata. If a horizontal bed is tilted, without faulting, either it must be stretched or the rocks below must move or be compressed to meet the new conditions. The jointing of the rocks in the Bullfrog district shows that there has been some stretching, though certainly it is insufficient to meet the demands required by any considerable crustal shortening. On the other hand, tensional stress is commonly regarded as a condition for normal faulting and this appears to be necessary if the blocks move downward freely without crumpling the strata. If the various sections of rhyolite No. 7, as represented in Fig. 3, were horizontal and placed end to end, the resulting section would be 33,600 ft. long. The horizontal distance over which the small sections are now distributed is 42,240 ft. The difference is 8640 ft., or 25.6% of 33,600, which, for the whole section, represents the apparent net crustal extension due to faulting and tilting. That horizontal displacement with gap, as shown in vertical section, does not always represent real extension of the earth's surface is apparent from inspection of Fig. 7, where both cross sections A–B and C–D show

gaps, while the plan ABCD shows an overlap. The movement represented has been along the strike of the fault, and while the area itself has been unchanged, the disposition of the surfaces of the individual blocks is different. Yet as seen in vertical cross sections A–B and C–D the faulting has resulted in horizontal displacement with gap. However, this extension is only apparent, for, as seen in plan, it is compensated by the offset with overlap. All three dimensions, length, breadth, and thickness, should be considered in the discussion of the problem. As there has been no appreciable change of density in the material of the rocks in consequence of deformation, it is evident that the thickness of a faulted block must decrease if the length or breadth increases. Part of the overlap shown in the map of the Bullfrog area may be regarded as the expression of the shortening in this vertical direction, as shown diagrammatically in Fig. 7. From an inspection of the diagrams above referred to, it appears that the whole truth is not to be gained by measurements of distances between points of separation of beds in a few cross sections. The operation serves to indicate the kind of effects produced, but it is not accurately quantitative. It shows only that extension has taken place along the line of section; it does not show how much of this is due to horizontal movements (heave) in the directions of strike of the faults. As already stated, the horizontal component of the movement is less, on the average, than the vertical component in those faults where the direction of movement is recorded by striae. It is estimated that about one-third of the apparent crustal extension shown in Fig. 3 is due to horizontal displacement of blocks along the strike of fault-planes by movement that does not effect a change of area, but only a change in position of certain blocks. In accordance with this estimate the extension of the surface approximately at right angles to the strike of the faults would be two-thirds of the 25.6% extension calculated from that shown in Fig. 3, or about 16%. Further, if the individual blocks retain their shapes and dimensions, it is evident that the combination of tilting and inclined faulting does not extend the area in a direction parallel to the strike of the faults, but only in a direction at right angles to this. If all the faults were strictly parallel, the areal extension would be the same as the linear extension in a direction at right angles to the faults. No correction for heave would be necessary and the general section of Fig. 3 would show directly an extension of about 16%. In other words, an area of 1 square mile would be, after faulting and tilting, 1.16 square miles.

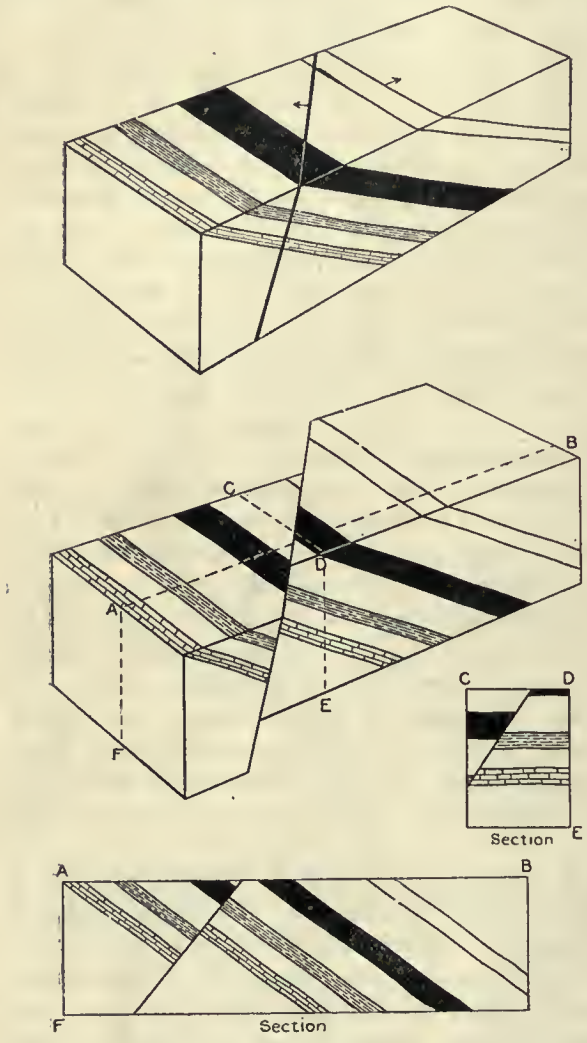

Fig. 7. Diagram illustrating some of the effects of heave along a fault in tilted beds. See text for explanation.

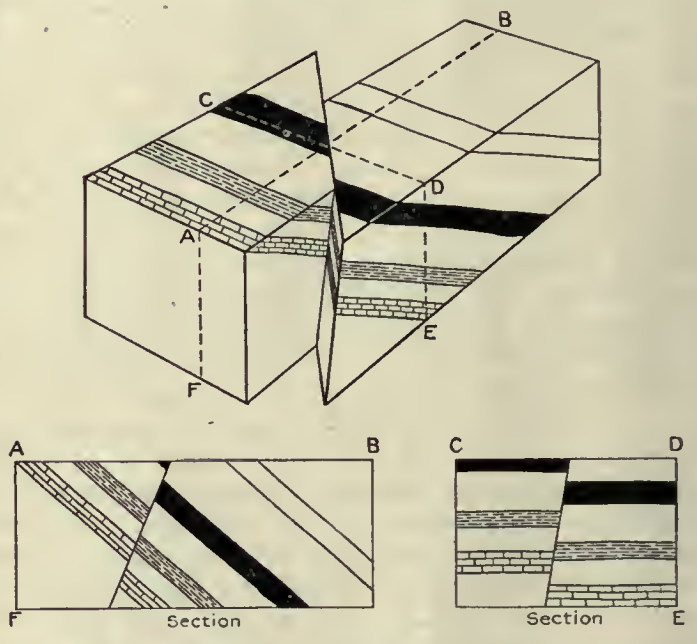

Fig. 8. Diagram illustrating effects of heave along a fault in tilted beds.

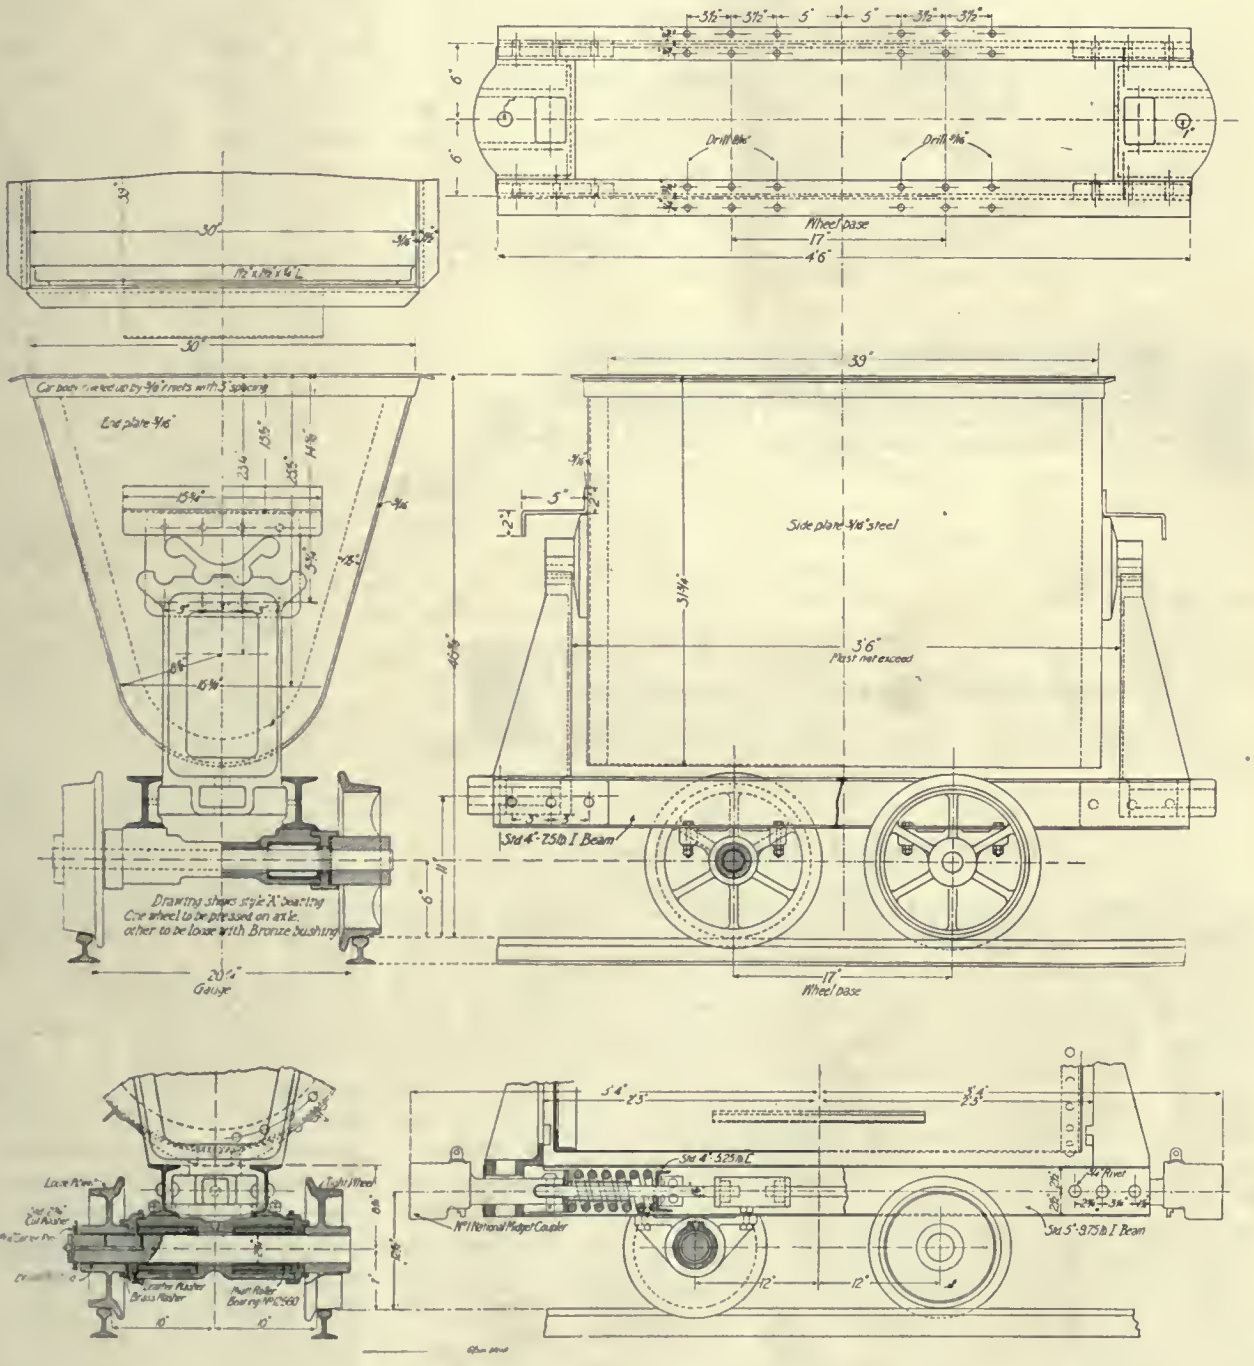
Production of minerals in Queensland for the quarter ended March 31, was £264,927 as against £284,755 in 1909. Following are the details, the figures in parentheses are for 1909: Value of copper, £179,773 (£180,532); silver, £13,966 (£31,552); lode tin, £25,103 (£19,682); alluvial tin, £19,874 (£6526); lead, £2123 (£25,482); wolfram, £17,011 (£4788); bismuth, £403 (£400); molybdenite, £1602 (£2819); manganese, £566 (£932). The value of the yields from the several districts during the quarter were: Archer River, £61; Bowden, £110; Charters Towers, £4095; Chillagoe, £51,289; Cloncurry, £12,416; Cooktown, £5478; Croydon, £288; Etheridge, £27,991; Gladstone, £1236; Gympie, £169; Herberton, £33,544; Ingham, £1744; Mount Morgan, £102,272; Mount Perry, £12,880; Palmer, £658; Ravenswood, £386; Rockhampton, £5740; Stanthorpe, £4629.

Side-Dump Mine Car

The accompanying illustrations show the details of construction of the side-dump mine car which has been adopted for use in the mines of the Copper Queen Consolidated Co., at Bisbee, Arizona. The body is made of $^3/_{16}$-in. steel sheet, strengthened at the corners and riveted with $^3/_8$-in. rivets spaced 3 in. apart. The truck is made of I-beams bolted to the axle-casing. One wheel is pressed on the axle, and the other runs loose, with a bronze bushing. The latter is held in place and protected from dust by a sleeve screwed upon the axle-casing and catching the hub of the wheel. Cast-steel upright supports are mounted on the truck to carry racks in which engage the pinions on the ends of the car-body, by means of which it is rotated. The design shown is for a car of 15 cu. ft. capacity. Similar cars of larger size, containing 33 cu. ft., are in use on the underground electric roads by which the ore is assembled from all the mines of the company at the pockets in the Sacramento shaft. These are equipped with drawbars and buffers, and use the No. 1 National midget coupler. Standard 5-in. I-beams are used for the framework of the truck. In both sizes of cars the rack and pinion is protected from dirt by ¼-in. steel shields. Details of the truck of the 33-ft. car are also given.

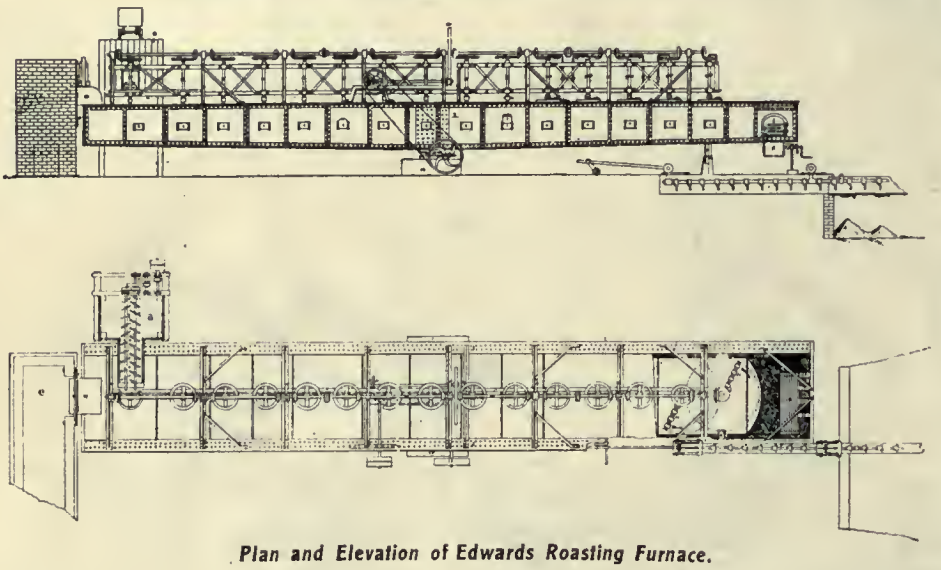
Cars of almost identical design are used at the North Star mine at Grass Valley, California. At the latter place such cars when employed for hauling concentrate in the mill, are drilled with holes in the bottom, and the inside of the car-body is lined with cocoa-matting, faced with No. 10 mesh steel screen, riveted to the steel-sheet. This forms a means for draining the concentrate. The Grass Valley car is illustrated in the lower figure. The details of these cars were worked out by Gerald Sherman, superintendent of mines at the Copper Queen, and formerly at Grass Valley, California.



Roasting at Kalgoorlie

By 'METALLURGIST'

*The discovery of telluride ore on Block 45 in 1896 and a little later on in the Lake View Consols mine, set the metallurgist experimenting as to the most suitable method for the treatment. Various schemes were tried, with varying amounts of success, until J. W. Sutherland, metallurgist of the Lake View Consols, tried roasting in the ordinary assay muffle furnace. After such roasting the ore was readily treated by amalgamation and cyanidation, and this induced him to make experiments on a large scale. In 1897 the first roasting furnace on the Golden Mile was erected on the Lake View mine. The furnace was after the style of the old hand-rabbled reverberatory of Victoria, the length being 15 ft. and width 11. As it was necessary to dry-crush the ore before roasting, the Lake View loaned one of the ball-mills at the Associated mine and crushed the ore through a ⅛-mesh screen. The results of roasting larger quantities were equally successful, and it is on these results that the foundation of the present roasting plants is based. It being decided in 1898 by Mr. Callahan, manager of the Lake View Consols, to install a properly equipped roasting plant, instructions were given to Mr. Pratt, the engineer, to proceed to the Eastern States and inspect and report on the roasting plants then in use. While he was making his report the Lake View Consols office was in communication with Europe, and when the whole of the information was available a Brown straight-line furnace was ordered, and in 1899 the two furnaces started roasting on a large scale, and had not the Swansea people supplied rope in place of chain for the rabbles, the obtaining of a sweet roast would not have been so seriously delayed. It is not intended to go into technicalities, but nearly every one is conversant with the varying results obtained, sometimes necessitating the blasting out of the sands in the leaching vats. While Mr. Pratt was away the Great Boulder Main Reef decided on a roasting plant, and sent Mr. Marriner, the metallurgist, to the Eastern States to inspect and report, and it was on his report that the Mt. Morgans shaft-furnace was installed on the Main Reef in 1899. In connection with this furnace, one of the newspapers went so far as to say that the Great Boulder Main Reef was the first mine here to pay a dividend on sulphide ore, and the extractions were given out at 96% of the gold content, although later investigations qualified these reports. While these two mines were roasting and completing the roasting plants, the Associated and the Kalgurli mines were erecting the Ropp furnaces, the Perseverance the Holtoff-Wethey, and the South Kalgurli the Brown straight-line. It was during 1900 that these plants were put into operation. The Great Boulder had pinned its faith to the Kooneman process, and under Mr. Kooneman's superintendence was erecting a gas-fired vertical-column furnace somewhat similar to the Stetefeldt. This was designed for roasting the ore in particles as large as nuts and to do away with the fine grinding which was necessary with all the other plants. Unfortunately, this plant soon proved a failure, and in 1900 the management chose Mr. Lilburne, the metallurgist, to take a sample of the Great Boulder sulphide ore to Ballarat to be roasted in the Edwards pyrite works. The trials were successful, and on his return the erection of a set of Edwards furnaces was undertaken. A feature of these furnaces was to be the gas-firing, and a gas-plant was installed, but the economy of gas fuel was not the success anticipated, and after a lot of hard work the officials had reluctantly to revert to wood for fuel.



Plan and Elevation of Edwards Roasting Furnace.

In 1901, with all the different types of furnaces roasting, the metallurgists were busily engaged in obtaining best results from the furnaces, and in comparing results with the adjacent mines. The mines were rapidly developing large sulphide orebodies, and an increase of roasting plant was becoming urgently necessary. The managements were anxious that the additional furnaces should be of the best of the different types, so naturally the roaster and roasting was the most prominent metallurgical topic. The Kalgurli mine was the first to admit that the Ropp was not suitable for the work, and in making additions to the plant discarded this type entirely and erected in its place the Edwards furnace, with a single line of rabbles, and with raising and lowering gear to alter the furnace hearth to any level which was thought necessary. Nine of these furnaces started work early in 1901. At about this time the Ivanhoe, which had been running a small tower furnace with a capacity of three tons per day, since February 1900, and the Brownhill, where the stamp-mill and wet-crushing with concentration was in use, decided that the concentrate being produced could

*Abstract from 'The Gold Mines of Western Australia'.

be more profitably treated by roasting at the mine than by shipping to the custom works, and placed an order for Edwards furnaces. The Ivanhoe installed three single-rabble and the Brownhill two similar furnaces. The results obtained after this change proved eminently satisfactory, the furnaces at the Ivanhoe being still in use. A fourth furnace was added in 1902 and a fifth in 1906, making a total of five Edwards Simplex furnaces in use at the present day. The Great Boulder management at this time was also anxious to increase the monthly tonnage of ore treated, and not being altogether satisfied that the Edwards furnace was the best, instructed G. M. Roberts to investigate and report on the Merton furnace. On his recommendation the company decided that the additional furnaces should be of the Merton type. These furnaces were duly installed and were working in 1903. The Associated company, now being thoroughly convinced that the Ropp furnace could be improved upon, were making inquiries as to what should be installed. All the furnaces were getting fairly good results, and in making the choice the company, helped by G. M. Roberts, who pronounced strongly in favor of the Merton, decided to erect ten of this type. These were complete and running in 1904. The Kalgurli had decided again to increase the monthly tonnage, and the South Kalgurli to overhaul its mill and make it up-to-date, and the question of the best type of roaster was exercising the minds of F. A. Moss on the Kalgurli and J. Morgan on the South Kalgurli. The Kalgurli decided on installing the Edwards furnace with a bricked-in hearth in place of the tilting furnace. The South Kalgurli replaced the Brown straight-line with the Merton. These alterations and additions were completed in 1905. The Golden Horseshoe, which was using the stamp-mill and concentrating, had decided to follow the lead of the Ivanhoe and Brownhill and roast the concentrate from the Wilfleys at the mine. The management approved of the Edwards plan of working with two lines of rabbles, in place of the single line as used on the Kalgurli and other mines. After going into the plans with the maker, J. W. Sutherland placed an order and constructed the first duplex furnace for roasting concentrate at the Golden Horseshoe in 1905. The results of this furnace were so excellent that the Perseverance, seeing the improvement that was possible with the double line of rabbles, made drawings for the replacing of the rabble of their Holtoff-Wethey furnaces by the Edwards duplex, and the using of the lower hearth as a conveyor and cooling surface. This alteration was successfully carried out by G. C. Klug in 1905, this being the first duplex furnace roasting sulphide ore on the Golden Mile.

The Associated was then putting in another Merton. The Associated Northern decided in favor of the Merton, while the Oroya-Brownhill replaced its Edwards by a Merton. The furnace practice had now settled down to the two types, with the exception that Mr. Dagger, of the Associated, had designed and erected a two-hearth furnace, practically a combination of the Merton and Edwards, and called it the Associated furnace. Each furnace finds strong support with masses of figures of costs and extraction to bear out the claims of the makers. It looked as if the two types would have equal support for all time, but Mr. Hamilton, of the Great Boulder, wishing to increase the tonnage and having both types of furnace in use having decided on erecting a duplex Edwards, and Mr. Roberts, of the Associated, the strong supporter of the Mertons following his example, settled all arguments and pronounced the Edwards duplex as being the most suitable furnace for the Kalgoorlie sulphide ores.

As showing the enormous strides during the last twelve years that have been made in the roasting practice, the small reverberatory on the Lake View and the up-to-date plants working at the present day may be contrasted. While the industry of Western Australia has reaped the benefit of all the work done by the engineers and metallurgists in this line, it may not be out of place to mention that at Cripple Creek, in America, where telluride ore was known to exist at a much earlier date than the Golden Mile, the method of treatment adopted was the smelting of the rich product only. That field has now adopted the Kalgoorlie method of treatment, and not only can the mines be worked at greater profit, but dumps formerly valueless have been treated at large profit.

At the present time there are working on the Golden Mile plants treating a total for the district of 73,000 tons of crude ore each month, and 5900 tons concentrate, a record for any part of the world, and, considering the high cost of material, the costs and extraction have not yet been equalled by any other mining centre. The detailed equipment is as follows:

The Great Boulder G. M.: 12 Edwards simplex, 8 Mertons, 2 Edwards duplex, roasting 17,800 tons sulphide ore per month.

Great Boulder Perseverance: 6 Holtoff-Wethey, altered to Edwards duplex, roasting 18,000 tons sulphide ore per month.

The Kalgurli G. M.: 9 Edwards simplex, and 4 Edwards duplex, roasting 10,700 tons sulphide ore per month.

The Associated G. M.: 17 Mertons, 1 Edwards duplex, and 1 Associated furnace, roasting 11,300 tons sulphide ore per month.

South Kalgurli: 10 Mertons, roasting 9000 tons sulphide ore per month.

Associated Northern: 6 Mertons, roasting 3600 tons sulphide ore per month.

Kalgoorlie Gold Recovery Co., Ltd.: 1 Edwards simplex and 1 Edwards duplex, roasting 500 tons sulphide ore per month.

Chaffers G. M.: 4 Edwards duplex, roasting 2000 tons sulphide ore per month.

Golden Horseshoe: 3 Edwards duplex, roasting 1800 tons concentrate per month.

The Ivanhoe: 5 Edwards simplex, roasting 1800 tons concentrate per month.

The Oroya-Brownhill: 3 Mertons, roasting 900 tons concentrate per month.

Lake View Consols: 3 Edwards simplex, roasting 1100 tons concentrate per month.

Hainault: 1 Edwards simplex, roasting 300 tons concentrate per month.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Classification of Igneous Rocks

The Editor:

Sir—Seeing the classification suggested in your issue of June 18, by E. R. Rice, I submit another variation of Kemp's classification that may be of interest to your readers.

IGNEOUS ROCK CLASSIFICATION FOR MEGASCOPIC USE From J.F.Kemp System

Acidic ← Light Colored						Dark Colored → Basic				
CHIEF Feldspar	ORTHOCLASE Alkaline, Potash, Monoclinic 2 Cleavages at rt angles Light Colored			BOTH in about equal amounts (Anorthoclase)		PLAGIOCLASE Lime-Soda, Triclinic, Oblique Cleavage Fine striations on new surface (Albite, Oligoclase Labradorite, Anorthite)				NONE
	± Hornblend - long slender ± Biotite - micaceous ± Augite - granular			± Hornblend - oblique cleavage ± Biotite - micaceous				PYROXENES Hypersthene Augite 2 Cleavages at right angles		
				± AUGITE		- AUGITE				
	+ Quartz	- Quartz	Nephelite or Leucite - quartz	+ Quartz	- Quartz	+ Quartz	- Quartz	+ Olivine	+ Olivine	± Olivine ± Hornblend ± Biotite
GLASS	Obsidian, Perlite, Pumice, Pitch-stones, Scorias									
Surface flows Few Phenocrysts Cellular Glassy Felsitic	RHYOLITE	TRACHYTE	PHONOLITE	QUARTZ-KERATOPHYR or PANTELLERITE	KERATOPHYR or LATITE	DACITE	ANDESITE	AUGITE-ANDESITE	BASALT TRUE BASALT	LABRADORITE AUGITITE
Dikes, Intrusions Laccoliths Porphyritic	RHYOLITE PORPHYRY QUARTZ PORPHYRY or SOLVITE PORPHYRY	As the texture approaches felsitic "PORPHYRY" is added to names above; as it approaches granitoidal PORPHYRY" is added to names below.						DOLERITE DIABASE

Some Matters of History

The Editor:

Sir—It has been my privilege to observe the development of the mining industry from within a short period of its inception, as in 1852 shortly after my arrival in California, I engaged in mining with pan and rocker in El Dorado county, and personally have participated in its evolution, from the 'long-tom', through the 'sluice', and the 'hydraulic' method up to 1860, when I took to deep mining, continuing in that occupation up to the present time. I was in Grass Valley in 1861 when there was not a revolving stamp or involute cam in use in that region, though it was then producing largely. Robert Watt told me that they had but lately discovered that thousands of dollars had been lost in sulphides. They were beginning to save them with Cornish buddles and rude shaking tables, shipping the product to Swansea for reduction. George F. Deetken started a revolution in gold saving at the Eureka mine in Grass Valley, when he succeeded in adapting the Plattner chlorination process to the profitable extraction of the gold from the quartz tailing which had formerly gone largely to waste, and his success undoubtedly inspired others to experiment, from which resulted the cyanidation process, as well as other great improvements. California is entitled to greater credit than is generally conceded for improvement in reduction machinery. In 1891 I was a member of the California World's Fair Commission of which Irving M. Scott was president, and at one time while at lunch in Chicago a gentleman came over to our table and shook hands with Mr. Scott, who introduced him to us as either Mr. Fraser or Mr. Chalmers, I now forget which, of the firm at that time engaged largely in the manufacture of mining machinery in Milwaukee. After he had left us, Mr. Scott made the statement that some years before the man introduced had gone over the mining region of California, and with pencil and paper had made drawings of the different quartz mills, and the various devices for reduction and gold saving purposes, all of California invention, and with that information had started in Milwaukee in a small way the firm of Fraser & Chalmers; which subsequently became the famous Allis-Chalmers company of world-wide reputation.

Science and Practice

The Editor:

Sir—Much energy is wasted because of lack of co-operation between men engaged in scientific research and those engaged in industrial work, more especially those who have problems of a practical nature. These remain unsolved, many times, from lack of this spirit. Men who are working along different lines grow farther apart the deeper each gets into his particular field if they do not, to some extent, work together. In general, the scientific man works for his own interest and improvement, his main object being to establish or break down some theory. To him theoretical considerations are of prime importance. This kind of work is most fundamental and must be done in order that knowledge may advauce along any particular line. As a rule the technical worker is engaged in the solution of a problem which will be of aid in some technical process. The scientific man has a better reference library at hand, more time to spend in thought, and, above all, less occasion for haste than one who is engaged in the solution of a practical problem, the non-solution of which means loss of money to those by whom he is employed. The library of the latter is frequently non-existent or, to say the least, very small. The routine work of the laboratory ofttimes also demands the greater part of his time and attention. This does not give him the opportunity for the clear thought, which should be given, in order that the best results be obtained in the least amount of time. Is it not possible for the man with the practical problem to make himself known to the scientific worker engaged in a similar line of work, so that he may find out what has been done along that line, giving the scientific man his practical opinion of the problem in hand, and, in return, getting the opinion of one who is engaged in pure science and not limited by consideration of cost? In this way the one would avoid, to a great extent becoming a 'fossil', and the other would get the help of an entirely different point of view together with the advantage of a library, which latter, as someone has recently and very much to the point said, "may be reckoned as so many thousand brain-power." An instance which recently came to my notice may serve to illustrate what can be done in

this direction. A friend of mine entered the employ of a large corporation for the purpose of solving some problems which proved stumbling blocks. The manager wanted to equip him a laboratory on the ground where he was to work. There it would be impossible for him to have many of the advantages that he could have in other places, and it did not appeal to him as the best way to get results. He finally came to an agreement with the company along an entirely different, and it would seem from what has been accomplished, very much better line. The arrangement is as follows: He is to work wherever he may see fit, his idea being to take his work progressively wherever the men may happen to be who know the most about the particular problem in hand, and to work with them, thus getting the advantage of their suggestions, specialized libraries, etc. This is one of the things which our higher educational institutions are for. Let us have more of this. I am sure, as far as I, myself, am concerned, that I would like to have more frequently the chance of consulting practical men.

Dry Holes in Oilfields

The Editor:

Sir—A question worthy of some discussion presented itself upon reading the comprehensive article on the California oil industry, by Courtenay De Kalb, published in your issue of June 11, 1910. The question was suggested by a portion of a single sentence and has to do merely with the use of words, although it first came to attention through doubt as to the correctness of the statement, which was, "As there has not yet been a dry hole drilled within the proved area." In an article of technical nature the term 'dry hole' seems subject to criticism, as it is a colloquialism with all the faults of such. It is particularly misleading when used in description of a well drilled for oil. In nearly every well drilled in California water is found at some depth, and in some cases nothing but water is shown in drilling. Such a well would be *non-productive* and in loose speech called a 'dry hole'. In many such cases the operators lament that it was not strictly speaking a dry hole, as there is a possibility of the water having held back and concealed some small showing of oil. Therefore it seems not too much to ask that such words be used as will express the meaning. The word non-productive does such duty. A second question also arises where the expression 'proved area' is used. If a well were non-productive could it strictly be said to have been drilled in a proved area? Such a spot would be proved to be barren, and if the writer understands the use of the word proved, as applied to mineral deposits, it means only that portion of the deposit which has been proved to be productive in an economic sense. In the oil business the term is overworked, and lacks in definiteness savoring of the ordinary newspaper.

Glass Separating-Funnel for Use in Laboratory Amalgamation Tests

The Editor:

Sir—The conical shaped glass separating-funnel shown in the annexed cut has proved to be an excellent elutriating apparatus in making bottle amalgamation tests in which the tailing and mercury were separated and assayed, much loss having occurred with other devices because a part of the slime was carried away by the wash-water. In using this funnel the lower cone is filled with clear water and both cocks closed. After amalgamation has been completed in the bottle, the content is emptied into the upper cone, water added to dilute the pulp, and the stopper placed in the top. After being shaken an instant the mercury settles and is drawn into the lower cone by opening the larger glass cock. Some of the sand will pass through with the mercury, but very little slime will accompany it if the lower cone has been filled previously with clear water. The glass stopper is then drawn and the tailing emptied on a filter, then the smaller cock is opened and the mercury drawn into a dish. If the mercury be floured it can be quickened with a little sulphuric acid and the quickened mercury poured off from the small amount of sand which descended with it. The separation can thus be made with no loss of tailing.

Wet Gold-Assay for Prospectors

The Editor:

Sir—I have read with interest the articles of Robert De Luce and J. W. Howson on the wet assay for gold. I have used the same method occasionally for the past year and the results have come much closer to the fire assay than those given by Mr. Howson. I always pulverized my ores to 100 mesh and then put the samples with the iodine solution into a very rapid shaking device which was permitted to run for one or two hours. I added the re-distilled mercury direct to the pulp and solution without any filtration and then washed the pulp away with a stream of water. If the mercury was divided I could finally bring it to one mass by using a little nitric acid. By washing and then pouring from one receptacle to another there was not much difficulty in getting rid of foreign matter. By not filtering there is no danger of any precipitation of the gold by the filter paper. I might add that I have never succeeded in buying any mercury absolutely free from gold, so I always use a 1 c.c. pipette and make an allowance for the gold in the mercury. This last point should be borne in mind. I have often used this method to disprove the claims of a number of chemical or secret process fakers who operate here.

John Herman.

Los Angeles, June 27.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Tungsten salts are used in fireproofing cloth for curtains and draperies, in weighting silks, in glass-making, as a mordant in dyeing, and in steel manufacture.

Chrome ores are no longer shipped East from the Pacific Coast States in quantity. The Baltimore and other Eastern plants now draw supplies largely from abroad. Western chrome ores are used in the rough for furnace linings, principally by the copper smelters.

The world's emery production is about 35,000 tons per year, of which 9000 comes from the island of Naxos, Greece. The right of mining the emery is enjoyed by the inhabitants of certain districts, the Government transporting the product to Syra, where it is sold for about $20 per ton. The Naxos emery contains over 60% corundum.

Re-location of oil placer claims so as to replace individual by association claims should not be attempted without the advice of a lawyer familiar with the specific conditions concerned. The law regarding re-locations, and the laws, decisions, and department rulings regarding oil placers are so complicated that no general rule can be safely laid down.

Black sands found in connection with placer gold often contain rare minerals of value. They may be separated by various well known concentration processes. The whole subject was discussed by D. T. Day and R. H. Richards in a report of the United States Geological Survey, 'Mineral Resources for 1905', pp. 1175-1258, and in Bull. 285; the reports being based upon tests made at Portland, Oregon.

Free ore, as the term is used in the Joplin district, means ore containing blende or galena that may be saved without crushing. It is customary to erect screens and hand-jigs and save as much of such ore as possible while the mine is being developed. The large blocks of 'crush rock' are stacked and often in this way a pile of ore is accumulated that is sufficient to pay for a mill in advance of the latter being built.

Costs and methods of road building are frequently given in the MINING AND SCIENTIFIC PRESS and other engineering journals, especially those devoted to general engineering. Valuable data may be obtained at any time on application to the 'Office of Road Inquiry', U. S. Department of Agriculture, Washington, D. C. Many States maintain corresponding departments, and a letter addressed to the State Engineer at the State capital will ordinarily reach the right department.

Mine inspection service is maintained by most of the American States, particularly those in which coal is mined. The reports of the mine inspectors contain data relating to production and accidents and often also a copy of the mining laws. Such reports are well worth having and are usually sent on application. When in doubt as to the correct address, a letter of inquiry sent to the State Mine Inspector in care of the Governor, will be referred to the right officer.

Calcite is found in connection with fluorspar in the Kentucky-Illinois district. It is a by-product obtained in jigging and was long wasted. Recently a market to the extent of three to five carloads at a time has been found in New York. The material is pulverized and used in paint making. The value lies, first in correcting any acidity in the mixture, and second in the action of the mineral as an inert reinforcing pigment. There would seem to be a considerable market possible.

Geological Survey reports usually may be obtained upon application to members of Congress. A limited number are available to the Director of the Survey for free distribution, but this does not apply to monographs, folios, and topographic maps, which the law requires shall be distributed by sale. Any of the reports may be purchased at a nominal sum from the 'Superintendent of Documents', who may be addressed at Washington, D. C. Upon application he will forward a price list. The Survey does not maintain any list of names of people to whom all reports are sent on publication, though certain designated libraries and exchanges so receive them.

Manganese occurs widely distributed either alone or with iron, zinc, or silver. A frequent mode of occurrence is as a residual concentration at the surface of the ground, and the ore is cleaned by screening and washing. The value depends somewhat on the content of other minerals, but in a general way ores containing 6 to 22% of manganese are mined and sold. Manganese is used in metallurgy to impart certain properties to iron and steel, and in the chemical industries mainly as an oxidizer. For steel making the price ranges from $5 to $15 per ton of 2240 lb. delivered at Pittsburg or Bessemer, Pennsylvania, or South Chicago, Illinois. The schedule of prices of the Carnegie Steel Co. calls for ores containing not over 8% silica or 0.25% phosphorus. Deductions as follows are made: for each 1% excess of silica, 15c; for each 0.02% excess of phosphorus, 2c. per unit of manganese. Ores containing less than 40% manganese or over 12% silica, or over 0.27% phosphorus are subject to refusal at the buyer's option. Settlements are based on weights of ore dried at 212°F. The schedule works out:

Percentage metallic manganese.	Price per unit in cents. Mn.	Fe.
Over 49	30	6
46 to 49	29	6
43 to 46	28	6
40 to 43	27	6

For chemical work the prices vary, depending on the percentage of manganese present, consistence of the ore, and special applicability. It ranges up to $25 per ton.

Special Correspondence

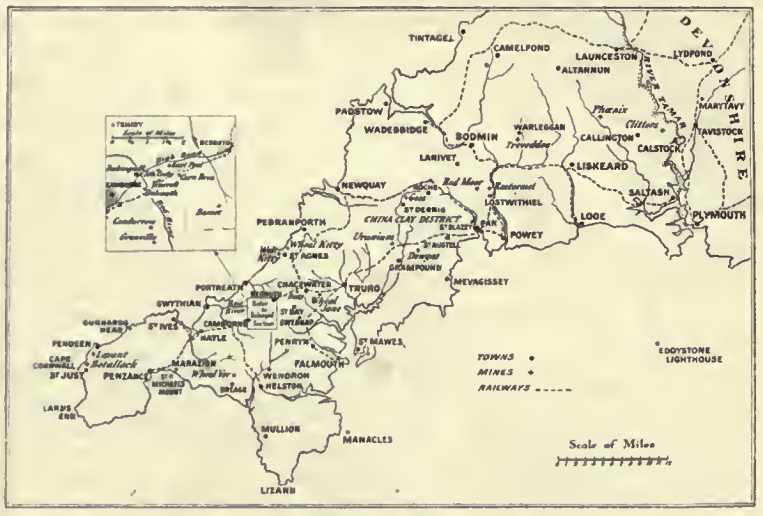
LONDON

Cornwall Mining.—East Pool and Agar.—Uranium. — Dredging for Tin.—Tronoh Tin Mine Improves Condition.

During the last year or so I have referred several times to the misfortunes of East Pool and Agar, one of the companies working tin mines between Camborne and Redruth. This company has done well on the surface and has introduced successful metallurgical methods of treating low-grade complex ore containing tin, wolfram, and arsenic, adopting air-cushion stamps and magnetic separation. While this good work was being done, underground developments were entirely neglected. No real development was done at all, nothing but scraping out the poor stuff left behind in days gone by when complex ores were valueless. At the present time the position of the mine is critical. Operations are carried on at a loss and all sorts of efforts are being made to convert the company from cost-book to limited liability concern and at the same time introduce the requisite funds for development. At the present time shareholders have been brightened by a discovery in the Agar section, where the newly introduced system of prospecting by cross-cut has revealed an excellent body of ore. This is encouraging and should help to save the old mine from going under.

Much has been heard recently about radium in Cornwall. The Uranium mine, at Grampound Road, ships pitch blende to Germany and receives something on the radium content, and the St. Ives Consolidated has a laboratory in London where Sir William Ramsay is to extract the valuable content. More recently it is announced that Madame Curie has bought pitch blende from Botallack. It has been known for years that the mineral is present in the mine and has been found on the dumps. In one of the workings it has in former years been sorted out before hoisting to the surface.

Exploitation of tin gravel is receiving attention in several parts of Cornwall at present, and there is some probability that an old industry will be revived on modern lines. In the high lands between Newquay and St. Austell, and also in the northeastern part of the county, gravels used to be sluiced at a profit, but many deposits are covered with peat-bogs and at others there is no water for washing or fall for disposal of tailing. One of the most interesting ventures at present is that on Goss Moor, directed by C. G. Lush. A dredge, built on Australian lines, has been erected and men experienced in its operation brought over. Then, again in the Fowey valley, north of Liskeard, F. W. Linck is testing ground with the Banca drill as a preliminary to erecting a Werf-Conrad dredge. The tests show a depth of 10 ft., averaging 16c. per cu. yd., with black tin at £80 per ton. The Tronoh tin mine in Perak, Federated Malay States, is now emerging from a prolonged period of mismanagement. The credit for the improved position is due to the new manager, Harry D. Griffiths. The former management had neglected to properly protect the surface workings from collapse and there was consequently a danger of the whole mine being lost. R. J. Frecheville agreed with Mr. Griffiths that open-cut working should be abandoned. During the past year the surface has been filled, thus preventing the accumulation of water and slime which used to cause dangerous rushes and floods. Underground the method has been adopted of working the deeper levels during the rainy season and the upper during the dry months. The whole of the 'karang' is now extracted instead of leaving poorer qualities behind. All these methods have been adopted so as to make settlement of the ground more even and regular, and to prevent as far as possible the accidents due to caving. The average content of the ore is lowered but the safety is increased. This is the part of the property known as No. 1 mine. In some parts it has been worked to bedrock, and the deposit cannot last much longer. Additional pumps have been provided in order to drain the underground water from the ground known as No. 2 mine and the pumping capacity is now 3,000,000 gal. per day. By this means the water-level has been reduced and it is now possible to start sinking shafts and undertake mining. Development has also been commenced on No. 3 mine. During the year 1909, the amount of 'karang' mined was 292,825 cu. yd. and 2159 tons of tin concentrate was recovered. This sold for £167,755 or £80 10s. per ton. The amount mined in 1908 was only 156,366 cu. yd. producing 1712 tons of concentrate. The cost at the mine was £115,937 and general expenses, depreciation, and taxes brought the expenditure to £137,187. The total income was £175,962 leaving a balance of profit of £38,774. The year commenced with a balance of £42,216; dividends at the rate of 10% absorbed £16,000, and £49,016 has been written off the property account, leaving £15,974 to be carried forward. An unpleasant feature of the former directorate was that the white and yellow managing directors had combined to lend themselves moneys belonging to the company. These debts are being gradually liquidated, but the yellow man has not been removed from the directorate despite urgent protests on the part of shareholders.



Map of Cornwall.

JOHANNESBURG, TRANSVAAL

Mines Training School.—Labor Statistcs. — Values in Depth. — Possession Island to be Prospected for Diamonds.

For many months past the Transvaal Government and the Chamber of Mines have had under consideration the establishment of a Mines Training School. At one time it was believed that the York mine, near Krugersdorp, would constitute a satisfactory property for the purpose, but after considerable negotiating and an examination of the mine by R. N. Kotze, the Government engineer, it was announced that it had been found impossible to carry out the idea of establishing a fully equipped training school, but that a start would be made in a fresh direction. Arrangements have now been concluded with the directors of the Wolhuter Gold Mines Co. whereby 50 youths under suitable instructors will take a contract at the mine under ordinary working conditions. Tenders will be invited at an early date for the erection of the necessary quarters at the mine and when these approach completion the Government Mines Department will be ready to consider applications from young men who wish to be instructed in mining. The Mines Department will provide for accommodation of learners and capable instructors will be appointed to look after the work. The training school will probably start toward the end of the current year. This establishment is, of course, distinct

from the Transvaal University College into the curriculum of which mining and metallurgy and the allied sciences and arts enter extensively.

Some highly interesting statistics relative to the numbers of natives employed by Witwatersrand mines have recently been published. The tables in question state the full complement of individual mines and the numbers actually employed. A column also sets forth the percentage ratio the former bears to the latter. Some of the mines had only about one-half their labor complement at the end of the year whereas others employed rather over 100% of their requirements. It is well known that natives have distinct likes and dislikes in the matter of employment on the Rand mines. In the first place they prefer outcrop properties to deep levels, since they can climb to surface after their daily footage has been drilled in them, whereas in deep-level properties they must wait their turn in an ascending cage or else undertake the exertion of climbing several hundred feet of ladders. Natives also prefer old compounds with earth floors and crumbling walls to the new brick and cement modern structures since the former more closely resemble their own habitations than do the latter. At the end of December last the largest employer of native labor on the Rand was the East Rand Proprietary which had 15,300 at work. The Randfontein South employed 11,141; Crown Mines 9734; the Geldenhuis Deep 5693; and the Rose Deep 5108; all the other gold mines had less than 5000 colored employees.

Some little while ago the mining world generally and the investing public at large were greatly concerned with the problem as to whether the conglomerate beds of the Witwatersrand were becoming poorer in depth or not. The increased contribution to the gold output of deeper-level companies together with the gradual decline in grade were the two factors which brought out a belief that the greater the depth at which mining operations were prosecuted on the Witwatersrand, the less would be the recovery of gold per ton. Authorities intimate with the policies of the controling corporations of Johannesburg, and the nature of the Main Reef beds, vigourously championed the view that the decline in grade was due to a reduction in working costs which brought large zones of low-grade ore within the limit of profitable extraction and treatment. This explanation of an economically sound policy appears to have been universally accepted, for during the last year or two one has heard but little from those who contended that the banket beds become impoverished in depth. But if the most up-to-date evidence in support of the statement that there were rich and poor zones along the dip of the beds as well as along the strike were needed one might cite the cases of the Witwatersrand Deep and the Angelo Deep as having a singular bearing on this important point. It is common knowledge that during the initial stages of development and crushing, the Witwatersrand Deep proved a most disappointing venture and its performances in comparison with those of neighboring mines at outcrops were taken to signify the lesser value of the conglomerates at depth. Of recent years, however, the Witwatersrand Deep has opened up in a highly satisfactory manner. It is now equipped with one of the largest milling plants under one roof on the Rand, and is one of the leading producers and profit earners on the entire Rand Gold Field. Today developments in the lowest levels of the property are disclosing better ore than in any other section of the mine. A parallel case is afforded by the Angelo Deep. Twelve or eighteen months ago this property was taken into the East Rand Proprietary consolidation scheme and there were not a few objectors to its participation in the amalgamation, for at that time the ore disclosed was barely profitable. Lately, however, the developments have been exceptionally good in this property and it might indeed be said that in few other sections of the East Rand Proprietary are such consistently good values being disclosed as in the Angelo Deep portion.

The Government of the Cape of Good Hope is about to commence prospecting for diamonds on Possession island which lies off the coast of German South West Africa. During the last two years a large number of stones have been found along the German mainland and on Pomona and other islands. All or practically all these islands belong to Great Britain and have hitherto yielded about £30,000 per annum to the Cape Government from guano. It is not proposed to proclaim these islands public diggings, not for the time being at any rate, as it is feared that a rush would ensue, the birds would be driven away from the islands, and the guano industry would be ruined. The intention is to place a Government prospector on Possession island and to await the results of his investigations. Numerous other islands are also to be explored. The diamonds of German South West Africa are found in the sands to the south and north of Lüderitzbucht. They are unassociated with the usual minerals and are believed by many to be alluvial or wind borne. Another theory which accounts for this remarkable occurrence is that they have been washed up by the sea from the bed of the ocean. The country is dry and arid and is one of the most windy and sandy on earth. There are a few waterholes at different points but most of the expeditions have to carry water for great distances, the beasts of burden employed being camels and donkeys.

MELBOURNE, AUSTRALIA

Coal Strike Disastrous.—Low Price of Metals.—Cloncurry Doing Well.—Mt. Morgan.—Gold Output Declines.—Deep Leads Fail.

Nearly six months of the current year has passed and in reviewing the results of the mining industry in Australia for that term it is to be emphatically declared that what with low prices, declining gold yield, and labor troubles the position is more unsatisfactory than it has been for some years. The greatest disaster which befell Australia was the coal strike at Newcastle, New South Wales. A number of socialistic agitators finding that the high wages which they had secured through the co-operation of the proprietors of the coal mines was attracting labor to the field and affecting employment, decided to strike. Through the intervention of the State Government work was resumed after a stoppage of some five months. But the industry is far from being in the position it was before the disturbance took place. The men are dissatisfied and the owners feel that they are walking on dangerous ground. As the result of the stoppage of coal exports to the East there has been a considerable falling off in the oversea trade. In Victoria the Government having found by boring that a large seam of coal existed in Southern Gippsland, at Powlett basin, has established a State mine. The effect of this enterprise will be to deprive Newcastle of much of its Australian trade. So it can be seen that so far as the working miner at Newcastle is concerned, he will have to adjust his conditions to the altered position of the local industry. This will entail considerable hardship owing to the shortness of employment. Matters are being still further complicated by the decision of the Federal Government to apply anti-trust legislation to the field. Considering that the combination of proprietors has resulted in the miners of the district having the mining rate raised from 3s. 2d. to 4s. 6d. per ton it is hard to see how they are to benefit by the operators combination being destroyed because such action would again throw the collieries into competition, and a lower rate of wage would prevail, strikes would follow, and probably an attempt to nationalize the mines. How this is to be done appears to be simple to labor extremists, but in actual practice unless a policy of confiscation be adopted, it will be extremely difficult to carry out.

The low price of the industrial metals has affected copper mining. Fortunately for the flotations in the Cloncurry district of Queensland, sufficient working capital was furnished at the outset to permit substantial development to be done. It is now established that several important mines exist in that far-away part of the continent. Of these the Hampden and Duchess mines have certainly opened up more satisfactorily during the last few months than any others. To increase ore reserves as has been done from under £500,000 to £1,100,000 in 12 months is no small feat, especially when a depth of only about 400 ft. has been attained. The Mount Elliott mine is the other leading mine of the district, and it will soon be smelting. Unfortunately here

the grade of ore at depth has been disappointing. Bewick, Moreing & Co.'s Great Fitzroy mine is between the devil and the deep blue sea; the ore is low-grade and the problems involved in its treatment are such as to cause the greatest anxiety. The engineers of the firm are now puzzling out how to deal with the concentrate of the silicious ore. On the other hand Mount Morgan has reached the point where in future it will be not only a great gold producer, but a great copper producer. The ore at depth carries about 3% copper and 6 dwt. gold per ton. The company will soon be able to draw upon supplies of pyritic ore from the Many Peaks mine.

The gold yield throughout Australia shows a decline. Taking the figures for the past four months of the current year they compare with those for the corresponding periods of the previous two years as follows:

	Fine oz. 1908.	Fine oz. 1909.	Fine oz. 1910.
Victoria	198,499	206,033	189,278
New South Wales	77,301	66,486	63,456
Queensland	133,408	127,411	139,893
Western Australia	556,353	520,159	481,110
South Australia..	2,600	1,400	2,480
Tasmania	20,000	20,000	14,800
Total	988,161	941,489	891,017
New Zealand....	150,077	135,843	142,070
Grand total ...	1,138,238	1,077,332	1,033,087

The reasons for this decrease are not difficult to state. In Western Australia, which holds the premier position, the mines on the Golden Mile, at Kalgoorlie, are all showing lower grade as depth is attained. Even the most important property, the Great Boulder, though keeping up its dividends, is proving no exception to the rule. The annual report of the Ivanhoe, another of the great mines of the field, discloses the same thing. By adding to the crushing plants the managers are endeavoring to maintain the rate of dividend but that means eating up reserves the more quickly. In Victoria deep-lead mining is in bad state, owing to the failure of the mines farthest down the leads to give profitable results. The water is heavy and the gold is distributed over a large area. With pumping charges so high the mines cannot pay. Bewick, Moreing & Co. have abandoned the whole of their deep-lead ventures in Victoria. One of these, the Berry United, has been taken up by a local company, but results are doubtful. Bendigo just about holds its own, but in Ballarat mining is almost past. In New South Wales the gold mining industry never has been a factor of any importance, but in Queensland it has. There the story is the same as in Western Australia; with depth declining values have to be faced. The position, therefore, is that unless in the vast extent of unexplored country in Australia some new goldfield be discovered, there must be a declining gold output. The only new field of any promise is at Tanami, in central northwest Australia. This is a desert region and although a number of prospectors are there, it is plain that the only chance of the field is for them to prove that the large reefs which exist carry gold in sufficient quantity for the State or private enterprise to furnish railway connection and so to make the place habitable. The South Australian Government has been successful in proving the existence of good supplies of water on the field by boring. Returns so far seem fair though the work done is so limited as to give no real idea as to the ultimate fate of the locality. Little alluvial gold is to be found as the reefs are not much disintegrated. Therefore, the necessity of more energetic work is evident.

At Broken Hill the Proprietary company still has its great mine shut down. This is entirely due to the fact that the workers urge that the industry must adjust itself to the wages and not the wages to the industry. Men to the number of 1900 consequently are out of employment and the company is confining itself to treating at its Port Pirie smelting works the lead concentrate which it buys from the other mines.

FAIRBANKS, ALASKA

Iditarod Rush. — Quartz Miners Stay at Fairbanks. — Placer Mines Short of Labor.—Gold Shipments.

There seems to be no doubt that there is some good ground in the Iditarod district, as gold has actually been brought back and weighed. Flat creek seems to be the richest, but pay has been reported on Willow, Black, and Granite creeks. That all the best reports have been believed was shown by the first big rush as soon as navigation opened. Small boats followed the ice down, while the big boats got away as soon as possible. Leaving within two days were the *Tanana, Delta, Tana, Dusty Diamond*, and the *Evelyn*, while the *Martha Clow* and the *Minneapolis* followed a day or so later. Four home-built steamers carrying passengers will sail shortly. All steamers leaving, except the *Minneapolis*, have carried limit loads of outfits and passengers. Before the fleet left reports that the stampede was not justified were received, but not heeded. Many have gone with the idea that if the Iditarod does not develop as expected they will move over the divide to the Kuskokwim. During May the stampede was unexampled from this camp. About 1000 people will leave here this spring for the new camp with freight aggregating at least 1500 tons. Many merchants are shipping stocks. Notwithstanding this efflux, the production of gold to date is larger than that of last year, and the season's output should at least equal that of last year. It is a significant fact that none of the quartz miners are leaving. The properties now being developed look too good to be deserted. During the month past the Tolovana Mining Co. shipped 10 tons of ore to the Fairbanks mill. This gave returns of a trifle over $70 per ton. The tailing assayed $2.35 per ton, showing that rock from their Willow Creek property is practically free milling. There is quite a movement in the stock of this company as a result. Stock in the Jupiter-Mars Mining Co. is also on the rise since the Redwing Mining & Leasing Co. has taken hold of part of the property. The leasing company is now actually engaged in sinking, and if the ore still holds its present values at 100 ft., a mill will be ordered this season. Until then, ore will be shipped to the new 10-stamp custom mill at Chena, which will be in operation by the middle of August. Emil Furstenau and S. R. Calvin are at the head of the leasing company. Another strike of galena at the head of Cleary creek shows 170 oz. silver per ton with a trace of gold. This find is reported by Burnett & Yachon. On Dome creek, Spaulding & Clough have timbered their 60-ft. shaft to hold it this summer and are driving an adit from the lower end of the claims. The vein showed 4 ft. of good ore under cover. On the extension of this lode a sample from the Wild Rose Mining Co., taken from the outcrop gave returns of $540 per ton. This claim is owned by Mrs. Spaulding, Mrs. Brumbaugh, Mrs. Meyer, and Mrs. Fairburn. Cook Bros. have located a new vein on Fairbanks creek showing about 2 ft. of base ore that assays $21 in gold and 57 oz. silver per ton. The ore is a mixture of iron and antimony sulphides, the antimony containing most of the gold and silver. They have also found a lode carrying scheelite, the first in this district that has been found in place. Both veins will be further prospected this summer. Herschberger, Buell & Phipps have discontinued work on the divide between Cleary and Eldorado on account of water. Though this was only a small amount of surface water, no means was at hand to handle it, and the partners have now moved to their property on Willow creek for the summer. Mellus & Nirich have found good ore on Willow creek, but the work has now been stopped by litigation. This vein seems to be the extension of that owned by Herschberger & Co., and exposed at the head of Cleary creek. Ten tons of ore run through the Fairbanks test mill by Mr. Rhodes from his Bedrock creek adit gave returns of $150 in free gold per ton. The adit is now in 550 ft. and still in good ore. An air-shaft will be sunk. The adit will then be pushed to the end line of the claim, as prospect shafts above show even better ore. Charles Crawford has finished his water-power arrastre at

his lease on part of the Rhodes lode. It is expected that there will be enough water in Bedrock creek to run all summer. It is probable that Mr. Crawford's example will be followed by many of the claim owners, at least till the custom mill at Chena is in operation. The vein owned by Lawson, Sommersett & McCarty shows better with depth. A pocket of rich ore was found recently that was suitable for jewelry. The quartz varies from 8 in. to 2 ft. in width and is practically free milling. This property is on the Fairbanks-Wolf divide. Having located a gold-bearing lode in the gneiss and quartzite at the head of Moose creek, Alois Fredericks has been cross-cutting to find the vein at a depth of 300 ft. Surface prospects showed good rock. The cross-cut is in 140 feet.

Placer miners are having some difficulty getting sufficient labor at present, although several parties of laborers have just arrived over the trail. It is thought that there will be no difficulty in a few weeks when boats begin to arrive from the outside. The oft-repeated assertion that Fairbanks placers are about worked out sounds out of place this season. Fish creek, where little has been done so far, has developed a good pay-streak, and many outfits are working. The lower end of Goldstream is beginning to show the pay from the famous No. 17 Below down to 26 Below. The valley is so wide it has taken some time to find the old channel, as the pay-gravel lies about 50 ft. deep. It seems now to be on the upper left limit. A new pay-streak has also been found on the second tier of bench claims opposite 7 and 8 Below Goldstream. After holding the ground for years, it was recently sold by Wade Joslin for $500. Shortly after, pay was found. The lower end of Dome and Vault creeks will show big production this year, and Eldorado promises to produce considerably. Since driving the long tunnel that drains the upper part of the creek where considerable wet ground was always found, no difficulty is anticipated. The first mail boat leaving Fairbanks took the maximum load of bullion, $1,000,000. About $500,000 was left in the vaults for future shipment. This was mostly from winter dumps. Sluicing is now general, and $10,000 to $15,000 pokes are being commonly filled

NEW YORK

Copper and the Market.—Imperial Copper Co.— Needles Smelter and Goldfield Ores.—Batopilas M. S. & R. Co.—Mineral Development Co. and Nueva Luz Shaft.—Oil and the Standard.

The absence in Europe of several of the important factors in the metal market, including Messrs. Adolph Lewisohn, John D. Ryan, Daniel Guggenheim, Urban H. Broughton, and Samuel Untermeyer, has given rise to the belief that some organization is being effected to control production. A heavy sale of copper abroad is said to be about completed, a sale which will take care of 100,000,000 lb. This is considered preliminary to the re-launching of the copper merger, which unfortunately refused to leave the ways last winter when flotation was attempted. In the meantime the porphyries are breaking all records. Utah Copper is producing at the rate of 142,000,000 lb. per annum, including its half interest in Nevada Consolidated. This production leaves but a small margin between Utah Copper and the Phelps-Dodge Co. as the second largest producers in this country. Utah Copper turned out 8,862,900 lb. during May, while Nevada Con. broke all previous records with an output of 6,000,000 lb. Inasmuch as the Calumet & Hecla has for some months been curtailing production about 14%, and the Phelps-Dodge people have stated that they were not crowding production, the inference is plain that the porphyry companies mean to use their overwhelming output as a club in securing a dominating position in any proposed copper merger. The board of directors of the Chino Copper Co. has been reduced from 15 to 9, the officers of the company are identical with those of the Utah Copper Co. Operations are under way at this property, which is to be on open-cut mine; steam-shovels being engaged in stripping the overburden from the ore. Steel is being delivered for the mill. The First National Copper Co., which operates the Balakiala, is turning out about one and a quarter million pounds of copper per month. The Imperial Copper Co. of Silverbell, Arizona, is one of the subsidiaries of the Development Company of America; it has for some years been developing its mines and building a smelter and now has a production of about 800,000 lb. per month. The company is about to be numbered among the low-grade milling coppers. Some of the ground recently acquired by the Imperial company has been exploited by diamond-drills and has developed some 7,000,000 tons of 2% porphyry. The ground in question lies between the original holdings of the Imperial and the holdings of the El Tiro Copper Co. Arrangements have recently been completed whereby the Imperial will take up the further development of the El Tiro ground. This will call for a smelter of several times more capacity than the present plant. The Development Company of America has recently organized an important railway project which will connect the Imperial Copper Co. plant with Port Lobos on the Gulf of California.

The Butte-Alex. Scott Copper Co., which is developing one of the promising new properties at Butte, has made a call of $1 per share; when the present payment is completed, $4 will have been paid. Some recent private sales of Boston & Montana are said to have been made at something above $500 per share. At the new smelter of the International S. & R. Co. in the first reverberatory is expected to begin operations about the first of August; the blast-furnace will not be completed for some months later. The first output will be copper matte. The first ores handled will be those of the Utah Consolidated and the Giroux.

The United States S., R. & M. Co. has almost completed its new plant at Needles, California, which is to have a capacity of 1000 tons per day and it is to handle the ores from the mines of southern Nevada. The Tonopah & Tidewater railroad has made a freight rate that will allow a great deal of ore previously thrown on the dump at Goldfield to be handled. Ores of $15 per ton value or over can now be sent to Needles and leave a fair margin for the operators. Contracts with many of the companies operating at Goldfield have already been made. The shares of the Batopilas Mining, Smelting & Refining Co. have been listed on the Paris Bourse; this company is the English concern, the control of which is held by the Batopilas Mining Co. L. H. Stevens, the president of the latter, died suddenly in London last week, just after completing negotiations for the financing of the English company. The factional fight in Cobalt Central has crystallized into a lawsuit, in which wrongful payment of dividends is alleged and the removal of the present officers demanded. The Mexico Consolidated M. & S. Co., which is a Boston promotion, the company operating in Durango, Mexico, is another concern now being rent by fractional differences. Some three years ago the company paid dividends of $1 per share and stock was quoted around $15. The shareholders are now endeavoring to learn why the quotation is less than $1 and the company in debt to the extent of more than $300,000. The first payment of the subsidy given by the Mexican Government to the Mineral Development Co., which is sinking the Nueva Luz shaft at Guanajuato, Mexico, has just been made. The Nueva Luz property adjoins the old Valenciana mine, which holds the record as the greatest single precious metal mine ever developed on the American continent, and the Nueva Luz is expected to open the dip of the Valenciana vein on the Veta Madre. The check given by the Mexican Government was for the sum of $3750, and covers 150 ft. of depth gained in the shaft. This subsidy is unique in the history of mining in Mexico and was granted to the Nueva Luz because of the importance to the camp of Guanajuato of opening again the rich ores of the Valenciana veins.

The growing interest in oil has received a setback on account of the present demoralized conditions, but there is one step in contemplation which will go far to establish the oil industry in its proper position among investments. The Standard Oil Co. is to undergo a reorganization. It is expected that the increase will be on a basis of five shares for one. The present distribution of profits is at the rate of 40% per annum; five shares of new stock for one of old would give the shareholders an 8% investment. There is a

possibility also of a part distribution of the immense surplus of the company as a cash dividend; if this is done, the Standard Oil Co. can easily dwarf all previous melon cuttings in financial history. The present surplus is estimated at $460,000,000, in addition to which there is oil in storage of an estimated value of $50,000,000, to say nothing of the plants and pipe-lines. Allowing only a nominal value for these, and the company's tank cars and steamships, it is evident that the shares have a book value of more than the present price of $625.

WASHINGTON, D. C.

Land Withdrawal Law.—Acting Director Bureau of Mines.

The full text of the land-withdrawal law as passed by Congress is as follows:

Be it enacted, etc., That the President may, at any time in his discretion, temporarily withdraw from settlement, location, sale, or entry any of the public lands of the United States, and the District of Alaska, and reserve the same for water-power sites, irrigation, classification of lands, or other public purposes to be specified in the orders of withdrawals, and such withdrawals or reservations shall remain in force until revoked by him or by an act of Congress.

Sec. 2. That all lands withdrawn under the provisions of this act shall at all times be open to exploration, discovery, occupation, and purchase, under the mining laws of the United States, so far as the same apply to minerals other than coal, oil, gas, and phosphates: *Provided*, That the rights of any person who, at the date of any order of withdrawal heretofore or hereafter made, is a bona fide occupant or claimant of oil or gas-bearing lands, and who, at such date is in diligent prosecution of work leading to discovery of oil or gas, shall not be affected or impaired by such order, so long as such occupant or claimant shall continue in diligent prosecution of said work: *And provided further*, That this act shall not be construed as a recognition, abridgment, or enlargement of any asserted rights or claims initiated upon any oil or gas-bearing lands after any withdrawal of such lands made prior to the passage of this act: *And provided further*, That there shall be excepted from the force and effect of any withdrawal made under the provisions of this act all lands which are, on the date of such withdrawal, embraced in any lawful homestead or desert-land entry theretofore made, or upon which any valid settlement has been made and is at said date being maintained and perfected pursuant to law; but the terms of this proviso shall not continue to apply to any particular tract of land unless the entryman or settler shall continue to comply with the law under which the entry or settlement was made: *And provided further*, That hereafter no forest reserve shall be created, nor shall any additions be made to one heretofore created within the limits of the States of Oregon, Washington, Idaho, Montana, Colorado, or Wyoming, except by act of Congress.

Sec. 3. That the Secretary of the Interior shall report all such withdrawals to Congress at the beginning of its next regular session after the date of the withdrawals.

Under this law the President, July 3, withdrew 8,495,731 acres of land valuable for power-sites, phosphate, and petroleum, lying mainly in the Western States and Territories, but including phosphate lands in Florida and oil lands in Louisiana. Much of this land had been covered by previous withdrawals. In the meantime the work of classification under existing laws has gone steadily forward. The Geological Survey is constantly valuing coal lands and recommending them for restoration to entry. The general effect of the appraisal of lands by this bureau is to raise the price. In May 1,097,261 acres of coal lands were reported. Of these, 329,334 were classified as non-coal land and the remainder valued, on a tonnage basis, at $58,508,120, as against $13,320,390 on the old acreage basis. The permanent Director of the Bureau of Mines has not been selected. Since some action was necessary on July 1, the President appointed George Otis Smith, Director of the Geological Survey, acting Director. There is much uncertainty as to when the permanent appointment will be made.

General Mining News

ALABAMA

FAYETTE COUNTY

For more than a year the existence of natural gas in considerable quantities has been known, in a small area three miles east of Fayette. This region was recently visited by David T. Day, of the United States Geological Survey, who reports that four successful wells have been drilled, showing gas with a closed pressure estimated at 600 lb. per sq. in., and nine additional wells are in process of drilling. The gas is found at a depth of 1400 ft. in a close-grained sandstone, estimated by the Providence Oil & Gas Co. to be 50 ft. thick. Small quantities of crude petroleum similar to that usually found in the Appalachian region were met at various depths above the gas. The strata pierced in the drilling consists of alternating layers of shale, sandstone, and tight sticky clay, under ideal conditions for the accumulation of gas and oil. It is estimated that 5,000,000 cu. ft. of gas per day can be furnished from the four wells now completed. The gas is pure and is free from sulphur. The thickness of the gas-bearing stratum and the pressure developed indicate a satisfactory yield of gas as compared with other known gas fields. The amount of development work thus far done is not sufficient to show whether a supply adequate to the needs of Birmingham for domestic and manufacturing purposes can be obtained. This will be determined, however, by the completion of the wells now drilling. Mr. Day urges the importance of detailed geologic mapping of Fayette county by the Alabama Geological Survey.

ALASKA

(Special Correspondence).—The operations of the Porcupine Gold Mining Co., on Porcupine creek, 40 miles from Haines, are in charge of S. C. Hunter this season, and the company anticipates a successful season's work. The bedrock flume has been extended and a high-line flume has been built from the Voegel flume where the latter comes into Porcupine creek. A steam-shovel has been brought and is used in lifting material from the bedrock and dumping it into the trolley lift, the latter discharging into the sluice boxes.——The Wonder Dredging Co., controlled by E. E. Powell and associates, is operating one dredge on Wonder creek and one on Bourbon creek this season, and is building another dredge to operate on Dexter creek, all of which are in Nome district. The dredge on Wonder creek got in a full season's work in 1909, and that on Bourbon creek operated 28 days of that year. The ground in which the Wonder dredge worked ran 45c. per yard; that in which the Bourbon operated ran a trifle higher. Thawing plants have been installed at each dredge and with these the ground can be thawed to a depth of 60 ft. The thawing expense is estimated to be 8c. per yard of material handled by the dredges. The two dredges in operation are handling nearly 6000 yards per day, and the one under construction is to be of the same capacity as each of the others. Mr. Powell is on his way to Nome from Seattle. Several small dredges have been shipped to Nome for work in various parts of Seward Peninsula.

Nome, June 23.

ARIZONA

COCHISE COUNTY

The new electric cables have been strung in the Sacramento shaft of the Copper Queen company at Bisbee and the pumps on the 1700-ft. level are easily handling all the water there.——E. Stiffler and associates have secured a lease on the vein of galena ore that was opened on the Don Louis side of the Wolverine & Arizona, and are preparing to ship to the El Paso smelter.——A consolidation of the California & Paradise Mining Co. and the Nebraska & Arizone Mining Co., operating in the Paradise district, has been effected, the new corporation being known as the California & Paradise Consolidated Mining Co. At present work will be centered at the Leadville shaft on the California & Paradise claims where a silver-lead ore is being opened,

and later operations will start on the copper deposits included in the Nebraska & Arizona lines.——The installation of additional boilers and pumps at the Bisbee Extension has been completed and work resumed on the 700-ft. level.——The Centurion will commence shipping some time this month. The ore will be hauled to Dragoon and forwarded from there to the smelter. Later a spur will be built to the mine.——Two carloads of machinery were shipped by the Young Brothers' Construction Co., of Los Angeles, to the Cicero Smith Mining Co., in the Dragoon district, and are now being installed at the mine.

GILA COUNTY

(Special Correspondence).—The Old Dominion at Globe is the scene of installation of new machinery and repairing of underground workings to an extent that may result in slight curtailment of the output during the near future. The shaft will be closed down for ten days until the installation of the new hoist is completed. On the extreme west side of the 1300-ft. level malachite was discovered the latter part of last spring in such quantity that it was supposed a large orebody had been reached, but this has proved only a pocket, disappearing in the limestone ten feet above the level. W. C. Carter recently took a lease on the Old Dominion's Transit claim, including a contract to sink a shaft on the same. At the 300-ft. level he cross-cut for ore, but development proved so unsatisfactory that he abandoned his lease. He has taken another lease on the Gray shaft and is now putting in a concrete foundation for a large electric hoist.——The Superior & Globe is installing the diamond-drill plant recently received and will begin its first drill-hole from the end of the north cross-cut.——Spencer W. Clawson of the Copper Reef reached Globe Wednesday evening. The two hoists recently installed on the property are in operation.

Globe, July 1.

PIMA COUNTY

The Cababi Mining Co., which operates the old Pichaco mine 50 miles southwest of Tucson, is sinking a new shaft with the intention of cross-cutting to the old workings at the 300-ft. level. The ore is high-grade copper-silver sulphides, and it is the intention of the company to equip the mine with additional machinery for the present needs, and later erect a reduction plant.

YAVAPAI COUNTY

Frank M. Murphy has purchased the properties of the Ideal Development Co. at McCabe which contain the old McCabe and Gladstone mines. These have not been worked for some time, but are credited with a good production in early days, $10,000,000 in gold bullion having been shipped from the McCabe alone.——The drift on the 400-ft. level at the group of the Pacific Copper Co. in the Silver Mountain district opened a 5-ft. shoot of copper sulphide ore that contains a high value in silver and gold. The company is building a road from the Minnehaha Flat road and will haul in machinery for further development when it is completed.

YUMA COUNTY

Plans for financing the Consolidation Copper Mines northeast of Parker have been completed and work commenced on the property, which consists of 140 claims. The new line which the Lewisohn interests are to build to the Planet mine will pass through the ground of the Consolidated, obtaining cheap transportation for the claims. These have been opened by a number of shafts when operated under separate ownership and a number of promising deposits of copper opened. The new company will commence work at the most central of these and sink a large shaft that will serve as a working avenue for the majority of the claims.

A hoist and power-plant is to be installed at the Golden Eagle property in the Quartzsite district this fall and the orebody prospected at greater depth. Several prospect shafts have been sunk on the ore opening it to a depth of 150 ft.——The Ciara Consolidated is installing a 350-gal. pump on the river to meet the increasing demand for additional water, insuring the camp an ample supply for domestic purposes and fire protection.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence).—The Bunker Hill has opened the vein for over 800 ft. near the 1750-ft. point. In places it attains a width of 30 ft. and carries good milling quartz. Cross-cutting from the 1950-ft. level still progresses and it is expected to intersect the vein about the middle of July. The monthly dividend of 5c. was paid on June 15. The head-frame was partly wrecked July 1 by a premature signal to hoist while a temporary track was being used. The skip jumped the track and shattered several braces and top timbers. The frame will be repaired temporarily, but a new one will be installed as soon as possible.——The Doyle lease on Amador Queen is developing stringers of ore in the hanging wall.——The scarcity of water is causing considerable uneasiness among local mining men, as it is feared that several companies will be forced to suspend operations before the end of summer.

Jackson, July 2.

EL DORADO COUNTY

W. C. Green has purchased a stamp-mill from the El Dorado Foundry at Placerville and will erect it at the Gold Channel mine near Georgetown where considerable rich gravel has been opened. There are several hundred acres in the group, and it is planned to have the mill in operation this fall.

NEVADA COUNTY

The North Star Mines Co. of Grass Valley has purchased the Minnie group, which is situated between the Gold Hill and Peabody properties. The property has not been worked for twenty-five years, though it is reported to have produced some rich ore when active.

SIERRA COUNTY

Several men have been added to the force at the Lookout mine near Alleghany and drifts are being driven along the 4-ft. vein that was recently opened. Several lots of ore have been taken from the drifts and will be crushed in the Sultana mill.——At Forest excellent progress is being made in re-opening the drift at the North Star placer which cut the Uncle Sam vein.——Arrangements are being made for the erection of a mill at the Kate Hardy.——F. W. Roher has secured a two years' lease on the Omega mine at Forest and has several men at work.——The hoist at the Gibraltar has been overhauled and work started bailing out the water.——The Cleveland mine at Scales has been shut down for the season on account of the lack of water, and cleaned up. It is estimated that $12,000 was taken out the last run.——The Lee Brothers, who opened a rich shoot on the outcrop of their claim in the Sierra City district, have sunk about 15 ft. on the vein and have erected a windlass to further prospect the ground.

SHASTA COUNTY

The smelter of the Bully Hill Copper Co. at Winthrop was shut down on July 1 to conform with the orders of the Forest Service, and about 400 men have been thrown out of employment. The smelter was practically re-built about two years ago when the Sacramento Valley & Eastern railroad was built from Pitt, on the Southern Pacific, to Winthrop. The motor-car service will be maintained on this line to carry mail and passengers, but the regular trains will be discontinued till some definite action is taken either as to building a bag-house or shipping the ore.——The Hazel Gold Mining Co. has given up its bond on the Uncle Sam mine west of Kennett and stopped work. It is reported that the company wished an extension of time on the same terms that it had been working under, but was refused by the Virginia Gold Mining Co., which owns the property.

YUBA COUNTY

W. W. Old and Earle Hodgins, representing Oakland capitalists, have secured a bond on the old American Flag group on Oregon creek between Camptonville and Sleighville and commenced work on the property with eight men. There has been considerable development on the group and some good milling ore has been blocked out. It is expected that a 10-stamp mill will be erected this fall if the development warrants it.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—Work was resumed this week on the Wide West mine on Leavenworth mountain. The adit, in 800 ft., is to be driven ahead to cut under the old workings from which $500,000 worth of ore was taken a number of years ago. H. Selfried is owner.——A contract is to be awarded this week for the driving of the Prudential adit another 100 ft. This will take the heading past two known veins that make a strong showing on the surface.——Work was resumed last week in the advance of the Raymond adit on Griffith mountain. It is to be driven 600 ft. more to intersect at depth a series of veins.——The ore-sorting plats at the Capital mine have been completed and now a much heavier output of smelting ore is marketed. From 30 to 40 tons per week of this product is being sold, average returns of 5 oz. in gold per ton being realized. The mill is treating from 80 to 100 tons of ore per day.

Idaho Springs, July 2.

GILPIN COUNTY

(Special Correspondence).—It is likely that before this appears in print the famous Gunnell vein will be intersected by the Newhouse tunnel. George Collins, the manager, states that for the last 20 ft. the heading of the adit has been passing through stringers of lead and zinc ore. The water in the shaft has receded to the 850-ft. level, while in the Grand Army shaft it is down 950 ft. When the vein is reached a drift is to be run on the Grand Army vein to cut under the shaft, when a raise will be put through to obtain a circulation of air.——Work is being carried forward in the sinking of the shaft on the Coeur d'Alene mine on Gunnell hill. The shaft is down 675 ft., but before any levels are started it will be completed for 800 feet.

Central City, July 1.

OURAY COUNTY

The Angel Mining Co. has commenced work on its property south of Ouray in Wehawken gulch and is expected to be on the shipping list some time this season.——William Rathmel, manager of the Savage Bear property, has gone East to confer with the stockholders regarding local treatment for the ore. In early days the high-grade ore was mined and shipped, leaving a large amount of low-grade blocked out that could now be treated profitably if handled at the mine.——The Ores & Metals Mining Co. resumed work on the group July 1 after a shut-down of a few months' duration.——John Erickson, who is in charge of the Mineral Farm mine, has received orders to resume work, and a shaft will be sunk to cut the limestone contact.——The shaft at the Legal Tender, now down 200 ft., is to be sunk to the contact this summer.——The Wanakah Mining Co., operating the Bright Diamond mines, is centering work in the adit on the Iron Clad claim, which is designed as the main working avenue of the property. The upper tram terminal is now under construction and the tram machinery is on the road to the mine. Arrangements have been made with the railroad company for the grading of a spur to the American Nettie mill, which is being put in order to handle the output of the mine.

SAN JUAN COUNTY

Work is to be resumed at the Gold King mine in the Silverton district early this month, a small force having been started to prepare the mine for more extensive development. The mill will be overhauled, and it is thought that the mine will be in condition to keep it running night and day in about four months.——The Gold Nugget has arranged for the installation of machine-drills.

TELLER COUNTY

The Savage Leasing Co., operating the properties of the Requa-Savage Gold Mining Co. in the Cripple Creek district, is reported to have found a better grade of ore by extending one of the old drifts in the old workings a short distance beyond the barren portion of the vein and is again shipping.——Jesse Adams and associates, who have a lease on the Carper shaft from the Free Coinage Gold Mining Co., have opened a shoot of ore on the contact of a basalt dike and a breccia. The gold is coarse and pans freely.——The drift on the 500-ft. level of the Jefferson mine in Victor opened a shoot of ore 250 ft. north of the shaft from which assays running as high as $680 per ton were obtained.——The Holberg & Morgan lease on the Ajax is operating on the 100 and 500-ft. levels and shipping 16 tons of ore per day that assays from $40 to $60 per ton.

IDAHO

LEMHI COUNTY

The vein of hematite which was opened on the 200-ft. level of the Pittsburg & Idaho near Gilmore has been proved to be 20 ft. wide and to assay $8 per ton in gold.——At the Iron Mask several hundred feet of development has opened a vein that assays 35% lead with a small amount of silver.——The adit on the Idaho claim of the Sharkey-Keim group is now in 150 ft. and is expected to intersect the vein within the next 75 feet.

SHOSHONE COUNTY

An assessment of one cent per share has been levied on the stock of the Copper King Mining & Smelting Co. at Mullen to raise money for the completion of the 3500-ft. adit that will tap the vein 1000 ft. below the old workings. On June 1 there remained 1166 ft. more driving to reach the vein, which is thought will be completed by the end of the year.

MISSOURI

JASPER COUNTY

(Special Correspondence).—The Center Creek Mining Co., one of the largest land owning companies in the district, has followed in the foosteps of other large companies near Joplin and is undertaking the development of the lower levels, most of which have hitherto been untouched.——The Little Mary, a new company operating on lands adjacent to the Quick Seven tract at Neck City, is rapidly becoming an excellent producer. The ore is high grade and abundant, resembling in all respects the famous run of the Quick Seven. A considerable amount of drilling has found the land well mineralized, not a single blank hole being drilled. The ore for the present is being cleaned on hand-jigs and is as rich as 40% in some instances. The contract for a mill has been let and a second shaft will be sunk at once. The Quick Seven mine has struck a layer of coal above the ore level and is using the coal for fuel at the mine and selling it to other companies. Usually the coal veins struck in this county are not of good quality, but the grade of this and the run found on the Whitworth farm is much better than ordinary and finds a ready market.

Joplin, July 1.

NEVADA

ELKO COUNTY

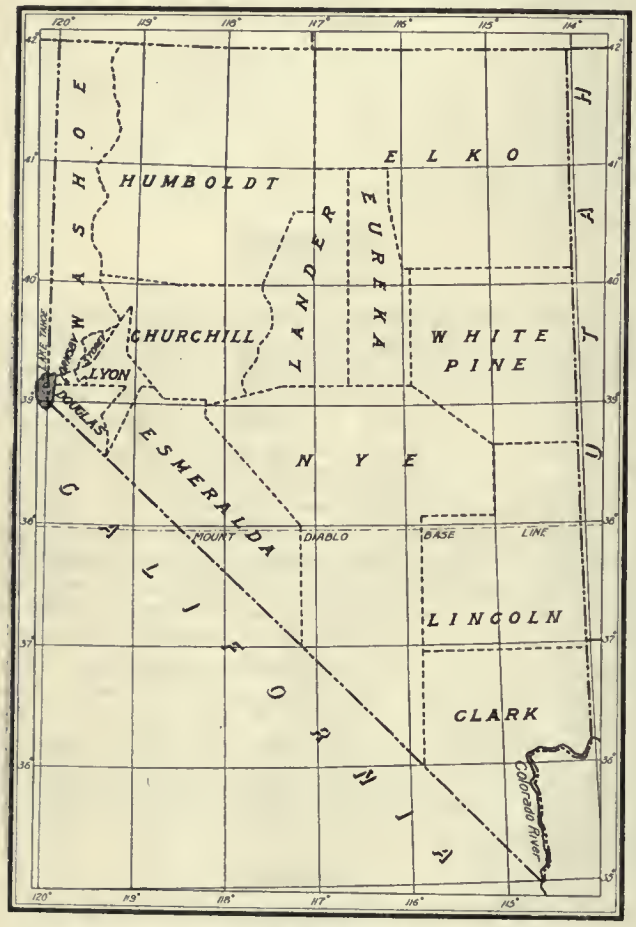
(Special Correspondence).—Three new discoveries at Jarbidge have been made the past week. The Riddle-Corrigan lease has cut the vein and it is 4 ft. wide, showing an average value of about $30 per ton, with streaks of high grade that run over $1000. This lease is on the Pavlak vein, about 300 ft. north of the 4-M lease. Good milling ore has been found in several places along this vein, but only one lessee had cut the high-grade. Of equal importance are the two discoveries about three miles east of the Pavlak vein. These were found in the Basin just east of Jarbidge peak, at the head of Jack creek, in what is called the Big Crater. These veins are about 130 ft. apart and quite different in the character of their quartz. They are both about the same size as far as uncovered along the surface, where they show from one to two feet of quartz containing free gold. The Van Alder vein is different from any before found; it is a white ribbon quartz with free gold, the average value being about $20 per ton, with no streaks of high grade showing on the surface. The other vein has a flinty quartz with streaks of brown decomposed granular quartz. Samples of the best ore gave returns of $441 to $2700 per ton. The quartz in this vein is similar to that found in the Pick & Shovel, Good Luck, and Free Gold claims. A company is being organized for the purpose of

erecting a custom mill here as soon as possible, and the Pavlak company is considering the erection of a mill at an early date.

Jarbidge, June 30.

ESMERALDA COUNTY

(Special Correspondence).—The production of the Goldfield district during the first half of the year 1910 was considerably in excess of $7,000,000, and it is estimated that even in the absence of further discoveries the total output for the year will exceed $16,000,000. This takes into account the fact that the Consolidated company has been operating for the past three months at greatly reduced mill capacity, that the Florence Goldfield has been treating low-grade ore as a considerable proportion of its product and will soon be in condition to increase its net output, that the Combination Fraction, after nearly a year in which no production has been made, has resumed milling operations



The Counties of Nevada.

with the certainty of a large output, and the further fact that several leasing projects are developing orebodies of proved value.——Three sets of lessees are operating on the Roseberry Rawhide group. The Veroqua lease is driving from the 200-ft. level to tap the vein opened near the surface, the Schmidt-Loutek lease is shipping small quantities of ore assaying about $30 per ton to the National mill, and the Rex is producing small consignments of shipping ore. ——The St. Ives lease on Queen has struck 6 in. of free-milling ore on the 400-ft. level.——The Grutt-Balloon Hill lease is developing a vein of rich silver ore and making occasional shipments to the Hazen sampler.——The Miller lease on Coalition is shipping 500 tons of ore to the Victor mill.——At the Pittsburg-Silver Peak, the 120-stamp mill is operating steadily and treating 15,500 tons of ore per month. The cost-sheet for May displays total expenses of $2.70, including 20c. per ton for repayment of funds expended in the purchase of the 20 additional stamps.——The Blair Salt Producers' Association is building vats and arranging to mine the salt beds near Blair.

Goldfield, July 1.

NYE COUNTY

(Special Correspondence).—The mill of the Tonopah Mining Co. is producing approximately $85,000 per week, 3400 tons of ore being handled in this period.——The Tonopah Extension Co. is arranging to exploit the recently acquired Red Rock and McKane group. An 82-hp. electric hoist is being installed to replace the steam-hoist.——It is reported that plans are under way for the flotation of a $200,000 bond issue with which to resume operations at the Lodi mines, in the northern portion of this county.——Minority stockholders of the Manhattan Dexter Co. have filed an amended complaint with Judge Mark R. Averill in which the officers are charged with mismanagement of the property, and an election asked for under the supervision of the Superior Court. Lessees have filed suits against the company because their leases have been declared forfeited, and the affairs of the company appear badly tangled. The mine is idle.

Tonopah, July 2.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence).—The vein on the sixth level east of the Socorro mines at Mogollon continues to widen as it advances toward the Queen lode. The vein in the breast of the drift, which is now 750 ft. below the surface, is 14 ft. wide and assays $32 per ton. When the drift is under the deepest portion of the hill 900 ft. of backs will have been obtained.——The Ernestine Mining Co. has secured a bond on the Top mine, the consideration being $350,000 worth of the Ernestine stock.——The 400-ft. station at the Deadwood has been completed and the shaft sunk 26 ft. below this point.

Mogollon, July 1.

OREGON

BAKER COUNTY

At the Union mine in the Cornucopia district the 20-stamp mill is running on ore that averages $15 per ton. The saving is made by amalgamation, concentration, and cyanidation. The Queen of the West in the same district has a 10-stamp mill in operation, 40% of the saving being on the plates. The concentrate is hauled to the railroad and assays $110 per ton. The ore is carried to the mill by an aerial tramway, the hauling, shipping, and smelting charges amounting to $25 per ton. It is reported that a cyanide plant is to be installed. F. J. Eitel is in charge. ——The adit at the Dewey group of claims, which is now in 150 ft., is to be driven an additional 50 ft., which is thought to be sufficient to intersect the vein.——D. L. Killigore, I. J. Leach, and J. A. Dygert have secured a lease on the Oro Fino group and will drive a 125-ft. adit to tap the shoot from which some rich ore was shipped to the Sumpter smelter.

UTAH

BEAVER COUNTY

During the month of June the Moscow Mining Co. in the Star district shipped 9 carloads of ore which was valued at from $30 to $40 per ton. The assays ran: lead, 30 to 50%; silver, 25 to 45 oz. per ton; and copper, 1½ to 4%. Recently a large orebody was opened by the 400-ft. shaft and a drift is being run on the 300-ft. level to connect with the same shoot.——The Commonwealth Mining Co. is to increase its force and continue work in the 100-ft. winze that was sunk from the 500-ft. level.

JUAB COUNTY

The Crown Point company, which owns a group adjoining the Colorado and Iron Blossom mines, is to resume active work on the property and will install electric-hoisting machinery. The shaft will be sunk from the 400-ft. level and the drift on that level driven on the ore.——The Coin Mining Co. has been incorporated to take over claims in the Tintic district that cover 160 acres.

SUMMIT COUNTY

The Silver King Consolidated is driving and raising on the 1550-ft. level, opening ore that assays $70 per ton. No effort is being made to get out ore for shipment, only that being forwarded to the smelters that is taken out in the development. Recently an orebody was opened that assayed

67% lead, 102 oz. silver, and $5 gold per ton.——Work is progressing satisfactorily on the 100-ton mill that is being erected by the Little Bell Consolidated Mining Co. at Park City. There are 40 men working at the mine and the management hopes to have the mill in operation some time in August. The Little Bell is shipping from 400 to 500 tons of first-class ore per month and storing the second class at the mine, 25,000 tons now being on the dumps.

TOOELE COUNTY

A new 250-gal. pump has been installed at the Ophir Hill mine that will be able to handle the flow of water that drove the men out of the mine some time ago and has kept a portion of the mine flooded ever since. It will take about a month to completely unwater the mine, when a large force will be put to work and sinking continued in the 600-ft. incline. The ore is lead-silver with a little copper and for the past eleven years approximately 4000 tons per month has been shipped.——The Silver Island Coalition has completed the installation of an air-compressor and good progress is being made in the lower adit. A small shipment of ore that is worth about $150 per ton is ready to be forwarded.

WASHINGTON

CHELAN COUNTY

The Wenatchee mine, situated 2½ miles from Wenatchee, owned by H. Leighton and F. E. Tift, of Seattle, has been equipped with a mill of six Nissen stamps, 1800 lb. each, and amalgamating plates, to operate on a low-grade free-milling ore. I. F. Laucks, of Falkenburg & Laucks, Seattle, is at the property in a consulting capacity. The plant, which was installed by Fairbanks, Morse & Co., is for preliminary work, and it will be enlarged if tests shall demonstrate profitable operations.

SNOHOMISH COUNTY

(Special Correspondence).—The Washington & Iowa Copper Mining Co. has done 2000 ft. of development on its claims situated 14 miles northwest of Index. It is claimed that four lodes have been intersected by a 1200-ft. cross-cut and that 400 ft. of driving has been done on these. The cross-cut opens the fourth lode at a depth of 1800 ft. The ore consists of sulphide of copper, iron, lead, and zinc, in a quartz gangue, containing gold and silver. The veins are said to be in a granite and porphyry formation. The property is on the north fork of the Skykomish river, in Silver Creek mining district. G. A. Rinehart, E. P. Hewitt, and N. B. Evans are among the interested parties. The equipment includes an air-compressor and drills.

Index, July 1.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—During May the value of the product of the plant of the Consolidated M. & S. Co. of Canada was $575,582, making a total for eleven months of the company's fiscal year of $5,420,737, as compared with $4,876,000 for the same period during the prior year. For the fiscal year ended June 30, 1909, the output was $5,506,000. This plant has produced $43,000,000 in the precious metals since it was started in 1894.——Another dividend of 50c. per share has been declared by the Le Roi No. 2, Ltd., and will be payable July 8. This property has paid dividends regularly, the total now amounting to something like $1,033,200. The property is equipped with an economical plant, and development and ore reserves are kept well ahead. This company shipped 2530 tons of select ore during May, and 136 tons of concentrate. The smelter receipts were $17.50 per ton for the ore and $17.93 per ton for the concentrate from second-class ore.——The Velvet-Portland mine has again been leased by E. Ehrenburg of Spokane, who made considerable money from his lease last year. Work will be started immediately.——The Rossland office of the Van Roi Mining Co. has trasmitted to London the information that during May the shipments from the property were confined to 220 tons concentrate and return from the smelter was on the basis of $103 per ton. The mill crushed 2709 tons, yielding 120 tons lead concentrate which assayed 167.9 oz. silver, 61.4% lead, and 13.7% zinc; and 100 tons zinc concentrate assaying 56.6 oz. silver, 2.7% lead, and 44.3% zinc. Zinc shipments from the property were delayed owing to a shortage of cars. A plan of diamond-drilling is being carried out at the mine which will shortly be completed.——The new 10-drill compressor at the No. 7 mine of the Consolidated company was started last week and active development of the mine with machine-drills will now commence. The four-mile tram is nearly completed and the surface plant about the property is in condition for quick and economical handling of the ore. Fifty men are at present employed.——At the Rawhide mine of the New Dominion Copper Co. a double shift was put to work during the past week, making over forty men now employed. The force will be gradually increased as experienced men can be obtained, good miners being scarce in this district just now.——Work on the Greenwood-Phoenix tunnel is temporarily suspended, but it is announced that operations will be resumed shortly.

Rossland, July 2.

YUKON TERRITORY

The Yukon District Gold Mining Co., operating in Windy Arm district, 12 miles from Carribou, has 40 men at work this season, and is making regular shipments of ore to the Tacoma smelting plant. The last shipment of 62 tons of ore sampled 1.11 oz. gold, 129.5 oz. silver, and 13% lead. The net return amounted to $89 per ton. A Canadian-Rand air-compressor and drills were installed last spring. Some shipments were made during the winter, the ore having been hauled over the ice to Carribou station. Shipments are expected to continue during the summer by boat to the railroad. J. H. Conrad, E. E. Harvey, and others are interested in the property.

MEXICO

MEXICO

Walter Pentland, for many years in the employ of the El Oro Mining & Railway Co., has been engaged by the Seguranza Mining Co. to take charge of its mill and cyanide plant. Practically all of the material for the tanks is now on the ground, the foundations for the cyanide tanks are all completed, and it is expected that within a short period the company will commence to treat the large amount of tailing which has accumulated since the concentrating plant was started some months ago. At the present time this company has stored in its El Bobo patio about 600 tons of milling and high-grade ore, treatment of which has been delayed, due to lack of transportation facilities to the hacienda, which lies on the opposite side of the mountain. To overcome this difficulty, rails have been ordered for a mule-car line, which will be constructed to the mouth of the No. 6 winze on the Coronas level, where all ores mined in the El Bobo level will be dumped, to be taken from chutes on the Zaragoza level below, until such time as the drift to the north on the No. 4 vein (Zaragoza level) can be connected with the winzes of the El Bobo level, when this transportation cost will be done away with. The Chontalpan mine, lying just across the State line in Guerrero, is producing large quantities of shipping ore. Machinery for hoists, drills, and pumps is arriving, being brought in by way of San Juan de las Huertas and Suitepec. The power to be used is producer gas. Arturo Bittner is in charge of the mine.

SONORA

The Sonora Central Mines Co., operating the Santo Domingo mine, lying between the Quintera and Zambona mines, Alamos, is erecting a concentration plant to mill the orebodies opened with 3000 ft. of development during the last year under the management of James R. Hendra. The Santo Domingo mine is one of the most noted antigua mines in the Alamos district. A 10-stamp mill constituting the first unit of the plant will be completed and in operation within 60 days. The mine is opened up to the third level and the main working shaft is being sunk to a depth of 500 ft., on completion of which it is proposed to add to the first unit sufficient stamps to give a capacity of 200 tons per day.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

S. J. Speak is visiting Australia.

W. A. Prichard is in San Francisco.

W. F. Thomae has been in New York.

Gelasio Caetani has gone to Arizona.

Frank H. Probert has been in Boston.

Claude T. Rice, of Salt Lake, is in San Francisco.

H. W. Turner has returned from British Columbia.

Fred. B. Reece is at Hostotipaquillo, Jalisco, Mexico.

J. M. Bell has been visiting Queensland and Tasmania.

Francis Drake has returned from southern California.

E. S. Bastin was married at Eastport, Maine, June 30.

E. F. Burchard was married at Evanston, Illinois, recently.

Henry A. Judd has gone to northern Nigeria for Lake & Currie.

J. A. Agnew, of Bewick, Moreing & Co., is expected in Canada.

George Otis Smith has been made Acting Director of the Bureau of Mines.

Edward Hooper, of Hooper, Speak & Williams, has gone to Western Australia.

L. C. Graton will spend part of July and August in the Shasta county copper region.

E. E. Powell, of the Nome Mining Co., started from Seattle, July 3, for Nome, Alaska.

Corey C. Brayton has returned to San Francisco from examination work in New Mexico.

Critchley Parker will soon be in the United States on his way from London to Australia.

Frederick H. Morley, of Denver, has gone to Vancouver, B. C., to examine mining properties.

Donald F. Foster is metallurgist for the Torres Mines, Ltd., Cherokee, Guadalupe y Calvo, Mexico.

Fred. L. Lowell and Norman C. Stines sailed on the *China*, July 6, on their way to Vladivostok.

Chester F. Lee, of Seattle, and associates are developing a mining property in Siskiyou county, California.

Ernest Williams has resigned the position of manager for the Great Boulder Perseverence and is going to Africa.

Andrew G. Larson, consulting engineer for the Le Roi mine, has opened an office at Vancouver, British Columbia.

H. H. Claudet recently returned to Vancouver, British Columbia, from Stewart district, adjacent to Portland Canal.

Louis S. Cates has accepted the position of superintendent of mines for the Ray Consolidated Copper Co., at Ray, Arizona.

A. D. Gassaway has returned from London and Siberia, where he has been for a year and a half for the Lena Goldfields.

Harrison E. Harvey, of Seattle, has established an assay office at Stewart, B. C., which is the centre for the Portland Canal mining activity.

The San Francisco Section of the Mining & Metallurgical Society of America will hold its next meeting at Grass Valley, July 22 to 24.

H. T. Willis has left the El Rayo Mining & Development Co. at Santa Barbara, Chihuahua, Mexico, and will be at Champaign, Illinois.

Charles S. Herzig, president of the Constant-Herzig Co., has left New York for an extended trip to the Western States on professional work.

Courtenay De Kalb has returned from New York, and will leave in a few days for Hermosillo, Mexico. He has received the appointment of general manager for the Pacific Smelting & Mining Co., and he also becomes president of the Mexican subsidiaries of that company.

Universities and Mining Schools

Will H. Coghill, of the Ore Testing Laboratory of Northwestern University, has developed a method of treatment for refractory manganese-silver ores.

Robert H. Richards, professor of mining at the Massachusetts Institute of Technology, accompanied by the mining students left for the summer school trip on June 10. The trip included a visit to the Michigan copper mines, the nickel mines at Sudbury, and the silver mines at Cobalt.

C. W. Hall, for many years professor of geology at the University of Minnesota, has retired. In connection with the appointment of his successor considerable re-organization in the department is expected and possibly arrangements will be made to revive the State Geological Survey.

L. S. Griswold has resigned the chair of geology at the Missouri School of Mines and will devote his entire time to consulting work. Guy Henry Cox, formerly assistant professor of mineralogy and petrography, has been placed in charge of the department of geology and mineralogy and raised to the rank of professor. J. W. Eggleston has been appointed to fill the position left vacant by the promotion of Mr. Cox. He is a graduate of Amherst, and of Harvard, and has had considerable experience in teaching geology and mineralogy in the Colorado School of Mines and Harvard University.

University of Alabama authorities during the recent commencement week, formally received two new buildings, Smith Hall, devoted to the studies of geology and biology, and Comer Hall, devoted to engineering studies. The dedicatory address for Comer Hall was delivered by F. H. Crockard, first vice-president and general manager of the Tennessee Coal, Iron & Railway Company, and for Smith Hall by J. A. Holmes, of the Technological Division of the United States Geological Survey. Smith Hall has been named in honor of Eugene A. Smith who has been professor of geology since 1871 and State Geologist since 1873.

The Trustees of the University of Pittsburg have adopted a plan of co-operation which will be put in operation this October, requiring the students of the colleges of civil, mechanical, electrical, chemical, and sanitary engineering to spend three months of the year in work outside of the university. They will be responsible to their employers and will receive the regular wages for the labor performed, but will have to report every two weeks to the college authorities. It is believed that this will enable a number of students to earn a large portion of their expenses while attending the university, to come in contact with firms that are employing engineers, and will place them in close touch with business principles and organization. The University of Pittsburg, because of its industrial environment, is splendidly situated to carry on this work and a number of local firms have made arrangements to co-operate with the colleges.

The Fritz Engineering Laboratory and the Eckley B. Coxe Mining Laboratory, of the Lehigh University at South Bethlehem, were formally opened June 11. The funds for the construction of the Fritz laboratory were donated and the plans drawn by John Fritz, known as the father of the steel industry in the United States, and a member of the board of trustees of the university. The building is of modern steel frame construction, and contains a 10-ton crane, equipment for testing strength of materials, and hydraulic apparatus for the study of problems in hydraulics. The Eckley B. Coxe Mining Laboratory is built of sandstone and is named in honor of Eckley B. Coxe, a mining engineer and trustee of the university in its early days. The main part of the building contains the ore-dressing laboratory, 40 by 70 ft.; the west wing contains a chemical laboratory, an assaying room, and a shop; and the east wing the office and recitation room. The locker and wash room is in the basement of the east wing. The equipment of this laboratory consists of stamps, amalgamating plates, grinding pans, rolls, gyratory crusher, screens, jigs, Huntington mill, classifiers, concentrators, and a cyanide plant.

Publications Received

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

FROM PROSPECT TO MINE. By Etienne A. Ritter. Pp. 166, ill. Mining Science Pub. Co., Denver, 1910. Price $2.

The story of how a prospect is found and how it may be developed into a mine is a fascinating one. It has been told briefly and well by Mr. Ritter. The book is excellently adapted to educate those who know nothing of mining and to give them a generally correct point of view. While occasionally lacking sharp definition, and while written loosely and carelessly in part, it is a good book and will prove useful.

IRON AND MANGANESE. By E. C. Harder, J. L. Rich, A. C. Spencer, and Sidney Paige. U. S. Geol. Surv. Advance Chapter from Bull. 430-E. Pp. 56. Washington, 1910.

This is a portion of the 'Contributions to Economic Geology for 1909', and includes accounts of iron ore deposits in California, Nevada, Pennsylvania, and Texas.

SURFACE WATER SUPPLY OF THE UNITED STATES, 1907-8. PART IV. ST. LAWRENCE RIVER BASIN. By H. K. Barrows, A. H. Horton, and R. H. Bolster. U. S. Geol. Surv., Water-Supply Paper 244. Pp. 163, ill., index. Washington, 1910.

Monthly Copper Review

*MISHA E. APPELBAUM

The copper market for the month of June has, on the whole, been a steady one, electrolytic selling as low as 12½c. delivered, 30 days, and as high as 12¾c. Domestic manufacturers continue their policy of buying from hand to mouth and since the production shows no signs of decreasing there is little incentive for them to change such policy. European shipments have been large and the metal has gone direct into manufacturers hands, but the key to the whole situation is the production. If production and deliveries continue at the present rate we are not likely to see any betterment in the copper prices, since that would not leave any room for reduction in the several hundred million pounds on hand now. It seems to me that the producers of copper are now realizing the necessity of taking less copper out of the ground instead of impoverishing the mines at a time when the price of copper leaves such scant profits, and I will not be at all surprised if several of the producers individually decide upon curtailment. It would be out of the question to have a general agreement to curtailment, since that would be contrary to the spirit of the law.

Deliveries for June will show for export about fifty million pounds, and with sixty-five million pounds domestic will equal the production, that is, within a few million pounds, and considering that Europe has decreased a smaller amount, total deliveries exactly equal the production.

*President New York Metal Selling Company.

German Copper Statistics

L. VOGELSTEIN & CO. give the following figures of German consumption of foreign copper for the months January to May, 1910:

	Tons.
Imports of Copper	69,700
Exports of Copper	3,312
Consumption	66,388

The consumption during the same period in 1909 was 62,709 tons. Of the above quantity 61,451 tons were imported from the United States.

Dividends

On Tuesday, July 5, the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 154 of $98,100. This makes the amount of dividends paid since January 1, 1910, $549,300, and the total to date $11,835,300.

TABLE OF CONTENTS

EDITORIAL

Announcement

The resignation of Mr. Courtenay De Kalb has made necessary certain changes in our editorial staff. Mr. De Kalb has been connected with the *Mining and Scientific Press* since 1907 as special contributor, associate editor, and finally as editor. He brought to the paper an unusually extensive personal acquaintance with Latin America, an intimate knowledge of mining, milling, and smelting, and an unfailing interest in legal problems relating to mines. His broad general knowledge and enthusiastic devotion to mining in every particular, has contributed greatly to the growth and influence of the paper. He leaves to become general manager for the Pacific Smelting & Mining Company which has large interests in Sonora, Mexico. Mr. De Kalb retains his interest in the paper, and will act as editorial contributor, so that our readers may anticipate hearing from him occasionally. There has been no change in ownership, and Mr. T. A. Rickard will, as in the past, contribute frequent articles and editorials, keeping our readers in touch with mining matters as seen in London. Mr. H. Foster Bain remains as editor, to be joined later by Mr. Thomas T. Read of the Imperial Pei-Yang University at Tientsin, China. Mr. Read is a mining engineer and metallurgist well known for excellent work in Colorado and the Far East. He has traveled extensively in China, Japan, and Manchuria, and before taking up his duties at San Francisco will spend some months studying the principal gold mining regions of the world. More complete announcements will be made later. In the meantime Mr. W. H. Storms, at various times in the past connected with the editorial staff and recently superintendent for the California Consolidated Mines Company, will temporarily assist in the editorial work.

AMONG coal trade journals *The Black Diamond* of Chicago is one of the best. Its increasing and deserved prosperity is reflected in the excellent special number with which it celebrated its twenty-fifth anniversary July 2.

CLAIM JUMPING on a large scale is said to be impending in the Midway oil district of California where recent investigations are reported to have shown much land to be held improperly. This is a striking commentary on the inadequacy of the present oil-land laws. Now that prices of oil have dropped a little and development is not so swift, it would be economical for the oil men to get together on a plan for a rational revision of the law.

FINAL PLANS for the Canal Zone meeting of the American Institute of Mining Engineers have now been announced. The party will leave New York October 29, returning about November 25 and visiting Havana, Kingston, and other West Indian ports en route. As accommodations are limited reservation should be made promptly.

THE International Congress of Mining, Metallurgy, Applied Mechanics, and Practical Geology at Düsseldorf, Germany, June 20 to 23, was well attended and particularly well managed. The discussions and papers were numerous and valuable. Interest centred in coal, iron, and steel as would be but natural in a meeting held at the home of the German Steel Syndicate.

DISCUSSIONS during sessions of the American Chemical Society meeting in San Francisco this week have been both interesting and helpful. Of especial interest to metallurgists was the symposium on smelter smoke which was on the program for Thursday morning. Of this we will give more account later. Friday the members of the Society visited the plant of the Selby Smelting & Lead Company where such excellent work has been done in solving the smelter smoke problem.

RECENT tests of the evaporative power of California oil under boilers at various points on the Isthmus of Panama have shown a minimum of 7.12 pounds of water per pound of coal, from and at 212° F., and a maximum of 14.22. The average was 12.31, and the majority of the tests gave results near this average despite great variety in the types of boilers. Even at the minimum efficiency, oil at $1.10 per barrel is cheaper than Pocahontas coal at $6.25 per ton, the price obtaining at most Isthmian points.

FROM an article on silver production at Cerro de Paseo, Peru, by Mr. Lester W. Strauss, which appeared in the *Inca Chronicle* of May last, we learn that the total output from the wonderful mines in and around that city of the clouds has amounted to three hundred million ounces of the white metal. The highest production for any single year was 3,100,000 ounces in 1842. At present silver ore is no longer treated in the native *ingenios*. The high-grade ores, containing more than 70 per cent silica and exceeding 30 ounces silver, are sold to the Cerro de Paseo company for converter lining.

PLANS for the work of the State Geological Survey of Tennessee have been announced and are excellent. The Survey is organized on a non-political basis, the Commission consisting of the Governer, Commissioner of Agriculture, Chief Mine Inspector, President of the University of Tennessee, and Chancellor of Vanderbilt University. As associates to the State Geologist, Mr. George H. Ashley, Mr. L. C. Glenn of Vanderbilt University and Mr. C. H. Gordon of the University of Tennessee, have been selected. Both these gentlemen are excellent geologists, and the plan secures to the Survey a close connection with the Universities at the same time that it remains independent, the offices being at the State Capital. A considerable amount of work is already under way in co-operation with the United States Geological Survey, the Department of Agriculture, and other Government agencies, thus not only supplementing the State's funds, but securing most effective correlation of studies. Thorough work is evidently to be done and a plea has been made for time before publication be demanded. In the meantime studies of oil and gas, of the Ducktown copper deposits, and of other resources are going forward in competent hands. An exhibition of the resources of the State will be made at the Appalachian Exposition at Knoxville, September 12 to October 12, and in every proper way the new organization will bring the light of science to bear on the problems of development of the State's resources. The thoroughness with which the preliminary work is being done augurs well for the results.

Bureau of Mines and Its Critics.

A recent editorial in the usually accurate and informed *Engineering Magazine*, forecasts dire results from the organization of a Bureau of Mines. In this instance our contemporary is seriously misinformed as to facts. How the conclusion is reached that the new Bureau is to be "distinctively administrative, regulative, apparently a part of the inquisitorial and hostile attitude toward corporations which is now so popular," is not apparent. Certainly no such conclusion can be drawn fairly from a reading of the law establishing the Bureau. This requires that the Director shall be a technical man and the technologic character of the investigations is not only emphasized directly in the wording of the act, but indirectly by the transfer to the new Bureau of the Technologic Branch of the Geological Survey. It should be noted that the statistical work was not so transferred nor was any of the work of any of the Bureaus of the Department of Commerce and Labor. There is written into the law an express disclaimer of any authority in the matter of mine inspection, and in every reasonable way, as it seems to us, it was made clear that the Bureau of Mines is to be a technical investigative organization, designed to take up the problems of mining at the point where the proper activities of the Geological Survey ceased. There has been persistent effort to misrepresent the facts in this particular and we are sorry to see that the *Engineering Magazine* has been made a victim. We furthermore differ as to the "political origin and character of the Bureau" or the "extremely small part, if any, that has been taken by representative mining men, responsible mining interests, or the representatives of distinctive mining States, in the demand for the establishment of the Bureau." Again we say our contemporary is clearly misinformed, as a perusal of our own news columns will show. It is true that a considerable number of mining men and mining engineers resident in New York have opposed the establishment of the Bureau or been lukewarm in its support. In this, as in some other things, New Yorkers have confused their own opinion for that of the country at large.

Growth of Reverberatory Smelting

Reverberatory smelting of copper ores is becoming more general in this country. The success attending the use of furnaces of this type already in operation at Cananea has led to the building of an additional furnace which will soon be placed in commission. The practice is the result of demonstrated economies in operation. If water-power were available the same commercial advantage would not obtain. It is mainly because the waste heat can be utilized in the development of power that the reverberatory shows marked economy as contrasted with the blast-furnace. As shown in a recent article published in these columns 0.77 barrel of oil is burnt in the fire-box for every ton of charge smelted. Of this amount only 0.33 barrel is chargeable to actual smelting while 0.44 barrel represents recovery in the form of steam generated in the boilers through which the flue-gases are conducted. At Anaconda and Salt Lake a like warrant for employing the reverberatories exists. An additional advantage consists in the greater flexibility of the reverberatory in taking care of sudden changes in the composition of the charge. The blast-furnace needs to be operated with great uniformity in order to yield the best results. Though it can be operated with wide variations in the percentages of silica and bases it is not economical when sudden changes occur. This statement may be debatable, but there is no doubt that the reverberatory is less sensitive in this regard. On the other hand it is true that the reverberatory will successfully smelt fine ore and flue-dust, while these materials when put into the blast-furnace produce an excessive amount of flue-dust, and herein lies another reason for the rapid growth in favor of the former type of furnace. The present situation of the custom copper smelters inclines the balance in the same direction. The quantity of concentrate offered is steadily increasing, while smelting ores are becoming scarcer. Furthermore siliceous ore is not so abundant as formerly, because of the expansion of milling and other forms of local treatment. Basic ores usually make considerable fine material, and this is not adapted to the blast-furnace. Thus the reverberatory finds a large field of usefulness, in spite of the fact that it is more particularly applicable to charges of relatively high siliceous content. It is easier to secure a serviceable acid than a basic fettling, and the dust from basic charges tends to corrode the arch and walls. The utilization of highly siliceous fine ore has been suggested as a means of overcoming this difficulty, the plan being to introduce a certain amount of such material at the beginning of each charge so as to give the arch and walls a protective coating of acid dust. Less basic dust would then adhere, and corrosion would probably be lessened.

It is stated that the Garfield smelter near Salt Lake may soon be using reverberatory furnaces almost exclusively. An addition to this part of the plant is already being made. This is being done in anticipation of the larger deliveries of concentrate from the Utah Copper Company's mills that will follow the reconstruction of the mill acquired from the Boston Consolidated. At the same time it is noteworthy that other custom ores are not being offered in such abundance to the Garfield smelter as to insure a supply sufficient for its blast-furnace plant. The new smelter of the International Smelting & Refining Company in Pine Canyon contains five reverberatories and no blast-furnaces. This is the first large plant to be constructed in America in which blast-furnace smelting plays no part. The reverberatories at Pine Canyon are 102 feet long, by 19 feet wide, and each will treat about 250 tons of charge per diem. It will be noted that the length of the furnace is less than that of the old furnaces at Anaconda, and it is considered open to question whether even this length is not greater than is actually required for economic work. There is a limit of size beyond which no gain is experienced. In the opinion of some experienced metallurgists no advantage is obtained by making a reverberatory longer than 80 or 85 feet. The smelting is finished at that distance from the fire-bridge, the remainder of the hearth serving only to admit of further separation of matte from the slag, and it is doubtful whether equally good results might not be obtained in a shorter furnace. This would apparently render it possible to recover a larger amount of heat from the waste gases, and make the smelting costs proportionally less. The Pine Canyon smelter, while built primarily to treat the ores of the Highland Boy mines, will also do general custom work. This makes all the more interesting the fact that no blast-furnace smelting will be attempted. All ores received will be crushed in the sampling mill to a maximum size of ⅝ inch. The crushing plant is exceedingly compact, and contains Blake crushers and rolls exclusively. The converter house contains one stand for each reverberatory, but it is doubtful whether more than two converters will be required. The furnaces and converters are all connected to a dust chamber 120 by 140 feet, and 40 feet high, the roof being of brick held by I-beams sustained by trusses on the outside, and further supported by steel columns surrounded by hollow masonry, the latter serving partly to keep the columns cool and partly to draw air into the tunnel beneath, where the dust will be dumped from hoppers into cars. The draft will be induced by a stack 350 feet high, 36½ feet diameter at the base and 25 feet at the top.

The present tendency is distinctly toward a more extended use of the reverberatory furnace, and important developments in practice are likely to follow. Modifications in size and in the lines of the furnaces are to be anticipated, all having for an object the introduction of higher economy. Conditions in this country do not favor the adoption of the Mansfeld practice with tall blast-furnaces and a closed top. By that means the waste gases may be utilized for the development of power, and the dust losses are kept within narrower limits. In America, however, ores suitable for smelting under such conditions are not abundant, and the reverberatory seems to offer a better solution of the problem where dependence upon fuel instead of water-power is necessitated.

BY THE WAY.

Under the title 'A Man of the East and West,' Edgar B. Bronson, long private secretary to Clarence King, pays a tribute to the great engineer in the July *Century*. From it the following abstract has been made.

King's keen sense of humor was ever kindly; and his shrewd, searching wit, while it spared no one, never descended to hurtful sarcasm. He had tenderness, charity, and the broadest of sympathies, yet at bottom the heart of an untamed Viking, happiest when battling with elemental nature and her creatures in their wildest moods. With a learning so comprehensive and profound that he stood among the foremost savants of his generation, the hours dearest to him were those spent in absolute or semi-savagery, listening to the droning songs of squaws about old Winnemucca's lodge-fire; idly dreaming about a Paiute village, watching its primitive tasks and games; garlanded in a merry Kalakauan fête or breasting the breakers on a Hawaiian beach, himself as daring and swift in the water as the lithest or sturdiest islander of them all; vying with the best *vaqueros* of Visalia in broneo-riding contests; wandering through the corridors of the San Luis Obispo Mission with a bent Franciscan, absorbed in tales of Junipero Serra's heroism and sacrifices, and mentally reconstructing the stirring scenes of the ecclesiastical conquest of California; trailing grizzlies into their Sierran lairs and there fighting and killing them; scaling untrod mountain-peaks; listening to the croonings of a turbaned black grandmother, hungry for some hint of voodoo mysteries—such were the experiences he best loved. With never more than an indifferently lined pocket, his was ever the generosity, and often the magnificence, of a prince. With an artist's adoration of color, a musician's love of harmonies, and a poet's worship of the beautiful, the exactions of his profession as geologist held him so fast that he was left little leisure for the exercise of talents and genius that might easily have placed him among the most brilliant devotees of the arts.

His father was James Rivers King, son of Samuel Vernon King, one of the first commercial adventurers in the China trade; his mother, Florence Little King, a woman of rare intellectuality. Early in his youth he showed such fondness for nature that his mother determined to direct him into the paths of science, soon choosing geology as his specialty. Prepared in the endowed High School of Hartford, in 1859, when seventeen, he entered the Sheffield Scientific School of Yale, where he was a pupil of the great Dana. The winter after his graduation, he spent studying glaciology under Louis Agassiz. Preparations for his scientific work finished, the spring of 1863 found King and his classmate Gardiner, with a party of pioneers, plodding the old Overland Trail from St. Joseph to California. Stopping in Virginia City to see the famous Comstock Lode, the burning of their lodging-house destroyed all they owned, but did not impair their pluck. Working as laborers in a quartz mill, in a few weeks they earned enough money to enable them to finish their journey. On the boat from Sacramento to San Francisco, they met Professor William H. Brewer, then assistant to Professor Whitney, the chief of the Geological Survey of California, with whom a little later King won his degree as mountaineer by a successful ascent of Lassen's Peak. For three years the two friends remained with the California survey, King as assistant geologist, Gardiner as assistant topographer.

At a large dinner at the Pacific-Union Club in San Francisco as late as 1891, attended by a score of the leading business men of the city, I well remember a remarkable scene in which all joined in acclaiming and toasting Clarence King as the savior of the reputation of California. "But for King," said one bank president, "the free flow of capital for developing our mineral resources would have been set back twenty years." The incident referred to was the famous diamond swindle of 1872.

Great as were the opportunities for his brilliant talents on the California survey, Kings' audacious ambition conceived nothing less than a transcontinental geological and topographical survey. In 1866, therefore, he resigned and returned East to undertake, single-handed, the task of winning approval and adequate appropriations from the President and Congress. The Fortieth Parallel Survey, begun in 1867, was finished in 1878.

The work finished, King planned a rest, surely much needed after twenty years of unremitting toil. But it was not yet to be. In 1879, several independent surveys were consolidated into one bureau as the United States Geological Survey, of which King reluctantly accepted the directorship. This post he held until the new bureau was effectively organized, when, two years later, he resigned.

The three years next following he spent abroad, studying the geology of Switzerland and Great Britain; reveling in color and ryhthm with Ruskin; discussing physics with Sir William Thomson (later Lord Kelvin); comparing mountaineering notes with his great compeer, Tyndall; dipping deep into the secrets of crystalline rock structure as revealed by Zirkel's microscope; chaffing bar-maids with Bret Harte; seeing all sides of English and Continental life; collecting art-treasures; buying Fortunys, laces, embroideries, old furniture, and a barber's basin, the famous 'Helmet of Mambrino'.

Returning home at the end of 1884, King's later years were spent in the care of his mining and cattle-ranch interests and in pursuit of his profession as a mining engineer, largely in Cuba, Mexico, and the Klondike. Many were the disappointments and sad the trials of his later years, unhappily; but the harder the blows, the bolder he faced them; the darker his horizon, the brighter he smiled.

At the very end, on his death-bed that sad Christmas day of 1901, his last recorded words were the expression of a witticism as gay and brilliant as any he ever flashed across a dinner-table. His doctor had remarked that perhaps the drug *heroin*, recently administered, had gone to his head. "Very likely," King whispered. "Many a heroine has gone to a better head than mine is now."

Economics of Secondary Enrichment—I

By A. M. Finlayson

GENERAL PRINCIPLES

Introductory. It may be taken as a truism that the process of formation of an ore deposit embraces not only its primary deposition, but the whole sequence of later events through which it has passed, up to the advent of man. Only on such an understanding do the vital processes of secondary alteration receive adequate notice in the study of the natural history of ore deposits. This is the more essential in view of the great importance to man of secondary and superficial processes in the alteration and re-arrangement of ores.

The principles of secondary enrichment were established ten years ago by S. F. Emmons, W. H. Weed, and C. R. Van Hise. Little has since been added to our knowledge of these principles, except in respect of chemical reactions. Detailed observations, however, have since multiplied enormously, and given data for deducing generalizations of practical value. The recognition, at the present day, of the great part played by meteoric waters in concentrating many ores, is an eloquent testimony to the spirit, rather than to the letter, of Van Hise's work. At the same time, it is a matter for surprise that so little practical use has been made of the work of the American geologists, and that the application of the principles involved has made comparatively little headway with a large portion of the mining profession, as was remarked many years ago by H. C. Hoover, in discussing oxidation at Kalgoorlie.[1]

The result is that many of the data now available have been collected from the geological 'obituary notices' of the important mining districts.

Economic Effects of Secondary Enrichment. These are twofold. In the first place, lean ores that might otherwise be worthless are concentrated into valuable products; and secondly, the alteration of ores is often of great metallurgical import, as seen in the formation of lead-carbonate ores, oxidized copper ores, and free-gold ores. In some cases, the primary deposit has been completely disguised by secondary processes, notably at Mount Morgan, Leadville, Butte, and Bingham. Further enrichment often involves as its correlative a zone of impoverishment, as in the case of the leached gossan overlying the enriched sulphides of copper. The great industrial significance of secondary alteration clearly demands an effort to grasp the criteria by which these effects can be foretold with reasonable accuracy.

It is advisable for the present to confine attention to the metallic ores, though it should be noted, in passing, that among non-metallic deposits, many of the important phosphates are the result of secondary concentration by meteoric waters, with removal of valueless gangue. Such are the leached guanos of the West Indies, the nodular phosphates of Doullens, the phosphatic coralline limestones of Barbuda and Aruba (West Indies), and the white bedded-phosphates of Perry county, Tennessee.

Alteration of Metallic Ores. As P. Krusch has pointed out,[2] metallic ore deposits are divisible into two general classes. In those of the first class, the superficial chemical changes, owing to the refractory nature of the ores, proceed more slowly than the physical processes of erosion, with the result that no secondary alteration takes place, the primary ore outcropping at the surface. Under this head come ores of tin, tungsten, chromium, platinum, aluminium (as corundum), manganese, and iron (as oxides). These same principles, however, which preclude superficial alteration result in the formation of valuable placers, as in the case of tin, platinum, and gems. Thus the formation of placers is a true enrichment accompanying processes of erosion. Primary deposits of these metals, moreover, are liable to relative enrichment near the surface, whereby, with the removal of gangue, valuable deposits may result. A notable example of this is at Mount Bischoff, Tasmania, where the gossan of the tin stockwork has lost much of the decomposed gangue by weathering in place. Local subsidence has taken place, producing a pseudo-stratified structure. To this fact are due the famous 'brown face' and 'white face', carrying layers of sand that in places contain as much as 10 or 15% cassiterite. A similar relative enrichment has been observed on a small scale in the gossans of Cornish lodes.

In deposits of the second class, the chemical processes normally outstrip the physical processes of denudation, and there results a zone of oxidation, succeeded by a zone of cementation beneath the ground-water level. This is illustrated by the ores of iron (carbonate), manganese (carbonate or silicate), lead, zinc, nickel, cobalt, mercury, silver, gold, and copper. Whether alteration and enrichment take place in such cases depends, however, on the relative activity of erosion. Thus, in recently glaciated areas, like Canada and Scandinavia, and in districts of active stream-erosion, the oxidation zone, and often the succeeding cementation zone, may be shorn off, and the primary ore will then appear at the surface, as in the other class. In the case of gold also, where denudation is active, a large proportion of the valuable ore will be found in the alluvium.

It is evident then that the character of the ore on the one hand, and the relation between erosion and oxidation on the other hand, determine whether an ore shall be enriched in place, or by transport.

Classification of Secondary Processes. Secondary alteration and enrichment embraces several distinct, though related, processes, for which the following scheme of classification is proposed:

1. Concentration by erosion and sedimentation.
   (a) Sedimentary or bog ores: Iron, manganese.
   (b) Placers: Gold, tin, platinum, gems.
2. Concentration from a disseminated condition in rocks: Nickel silicate ores, manganese, some lead and zinc ores.
3. Oxidation.

[1] *Trans. Amer. Inst. Min Eng.*, Vol. XXVIII, 1898, p. 758.

[2] *Zeitschrift für Prakt. Geol.*, Vol. XV, 1907, p. 129.

(a) Gossan enrichment: Many hematite and limonite ores, gold, silver (haloid ores), oxidized copper ores, etc.

(b) Residual deposits (with relative enrichment): Tin, manganese, iron, aluminium (bauxite).

4. Cementation and sulphide-enrichment: Copper, silver, gold.

The Water-Zone. The simplest conception to serve as a basis in interpreting secondary alteration is that of the water-zone, as defined by T. A. Rickard.[3]

The upper limit of the water-zone is the ground-water level, a level which is dependent on the local factors of climate and topography, and the physical and chemical nature of the rocks. The ground-water level marks—in principle, rather than in practice—the lower limit of the zone of oxidation. The lower level of the water-zone, or basement-level, is the level of maximum water-inflow in freshly opened mine-workings. Beneath this point, mines become gradually dry, until at depths of 2000 ft. or more, water ceases to circulate. Fissures and fractures, and subsequently shafts and adits, depress this basement-level, so that it sends projecting tongues down into the dry 'tight' region, as has been figured by Rickard. In general, the depth of the water-zone, as existing prior to mining operations, determines the depth of secondary alteration. Thus ore-shoots of secondary origin, or 'vadose' shoots, run horizontally in the longitudinal section of the vein, and, like the water-zone itself, send down tongues or teeth of altered ore like wedges into the primary ore beneath. Beneath the point of maximum water-inflow, the mine is in general working on primary ore. The depth at which this occurs is dependent, like the ground-water level above, on climate, on the character of the country-rock, on the occurrence of fissures and faults, and on other factors. Thus, in the Lake Superior region the basement-level varies between 600 and 900 ft., at Butte—a highly fissured area—it is nearly 2000 ft., at Cripple Creek it is 500 ft., at Rossland, 300 to 350 ft., and at Kalgoorlie, about 600 ft. The depth of oxidation is determined in the first place by the depth of the water-table, but owing to disturbing causes, the two are seldom coincident. In the first place, oxidation frequently extends below the water-level, as at Kalgoorlie and at Waihi. At Umkondo, in the Victoria district of Rhodesia, cupriferous shale contains malachite and azurite to a depth of 600 ft., while the ground-water level is at 100 ft. In the second place, the ground-water level is often much deeper than the base of the oxidized zone. This is the case in rugged mountainous districts with abundant rainfall and vigorous erosion. Thus in the Silverton district of Colorado, oxidized ores were shallow and of minor importance, while the ground-water level is from 50 to 200 ft. deep. It also results in arid regions, such as the Great Basin of western North America, which formerly enjoyed a humid climate. The climatic change to aridity is accompanied by a depression of the ground-water level, which then outstrips oxidation. Thus, in Sonora, Mexico, where the average rainfall is only 11 inches per annum, rich silicate ores occur to a depth of from 200 to 400 ft., while the ground-water level is considerably deeper. At Ely, in Nevada, the oxidized zone is from 100 to 150 ft. deep, and the water-table is at 335 feet.

ENRICHMENT OF TYPICAL ORES

Iron. The bulk of the iron ores mined today owe their value either to oxidation in the presence of circulating meteoric waters or to processes of denudation and sedimentation. Examples of the former are the ores of Lake Superior, which supply 80% of the United States output, and nearly three-fourths of the world's iron, and the Cleveland and Cumberland hematites of England. Important sedimentary ores are the Clinton ores in the United States, and the black-band ores of Scotland and South Wales. Most of the western European deposits are the result of superficial processes. Carbonate ores, such as are abundant in the United States, are of little value at the present day, though they are to be reckoned as a future source of supply. The Bilbao deposits owe their great value to the oxidation of spathic replacement deposits, and, with the mining of the unaltered carbonates of late years, the end of this supply appears to be in sight. Primary deep-seated ores, such as the titaniferous magnetites, have not yet been turned to account. The magnetites of middle Sweden, and the magnetites of Swedish Lapland, on the other hand, do not owe their importance to superficial processes, at least in late epochs. The specular iron ores of Elba, which have been generally regarded as allied to contact deposits, are considered by De Launay[4] to be due to the oxidation of pyritic ores by circulating waters energized by later igneous intrusions following fracturing.

If this be the case, it is a striking instance of secondary oxidation by an unusual combination of agencies.

Manganese. The principal sources of manganese ore are conspicuous examples of secondary concentration, sometimes by normal weathering processes with the concentration of residual ore, and sometimes by sedimentation, with the formation of lake or bog ores. Notable instances of the former process are the great deposits of maganese ore in India, those of the Bukowina in Austria, Minas Geraes, Georgia, Virginia, and the Batesville region of Arkansas. The ores of Kutais in the Caucasus, and of Nikopol on the Dneiper are Tertiary bog ores formed from the erosion of manganiferous rocks.[5]

Aluminium. The bauxites of Pûy de Dome and Antrim, the Westerwald, the Vogelsberg, and Silver City (New Mexico) are due to the weathering and decomposition of basaltic rocks by atmospheric waters charged with suitable solvents. Many laterites, such as those of India, and of west and southwest Africa, have had a similar origin. The formation of bauxites and laterites is a phenomenon of secondary altera-

[5]J. H. L. Vogt, *Zeitschrift für Prakt. Geol.* Vol. XIV., 1906, p. 217.

tion dependent on special climatic conditions.

Mercury. Secondary ores play a small part in the economic geology of mercury deposits, which in practically every case owe their value to primary cinnabar. Oxidation above the ground-water level results in the formation of native mercury and calomel, and some oxychlorides of mercury. These last have been a remarkable feature of the Terlingua quicksilver deposits, but in general, oxidation products are of minor importance. The formation of such oxychlorides is probably, like that of silver chlorides, a result of the salinity of the ground-water in arid regions.

Nickel and Cobalt. Secondary alteration is a variable factor with ores of these metals. The nickeliferous pyrrhotites, such as those of Sudbury, have undergone no superficial enrichment. This is indeed the case with the majority of magmatic segregations or similar deposits of deep zones, owing partly to their refractory nature, and partly to their massive unfissured structure. On the other hand, the nickel-silicate ores of New Caledonia and elsewhere owe their value entirely to concentration from a disseminated condition by circulating waters of meteoric origin. The ore first mined in New Caledonia carried from 5 to 10% nickel; in 1901, at greater depths, the average content was 4%. The cobalt ore (asbolite), of New Caledonia, associated with the nickel deposits, affords a striking example of concentration of residual ore by weathering.

In the case of nickel and cobalt veins, the chief effects of secondary alteration are the formation of bonanzas of native silver, and enrichment of nickel and cobalt in the gossan. At Cobalt the masses of silver found at and near the surface appear to be of secondary origin, but owing to recent glaciation, the gossan has been removed from the upper parts of these veins. At Silver Islet, in Lake Superior, similar bonanzas of native silver were found, and at Annaberg, secondary silver chlorides with native silver contributed largely to the wealth of the mines. In the famous veins of Schneeberg, oxidation in places reached a depth of 550 ft. while the maximum depth of mining was not more than 1500 ft. In the upper parts of these veins, erythrite and asbolite were abundant and furnished the supply for the cobalt industry when it began in the 15th century. Since the characteristic sulphides of nickel and cobalt are end-products, they alter directly to oxidation-products, and there is thus no sulphide-enrichment beneath the zone of oxidation. Further, the gossan enrichment of these ores is the result of aggregation of the ore rather than of an actual increase of the metal in the mineral formed, as in copper ores. Thus, smaltite and cobaltite carry respectively 28.2 and 35.5% cobalt, while pure erythrite carries no more than 37.5%, and asbolite considerably less.

Lead and Zinc. In the case of ores of these metals, the important phases of secondary alteration are three, namely, the formation of cerussite, of calamine, and of secondary silver. The first two processes owe their economic significance to the fact that the enrichment is not a mere increase of metal but an aggregation of ore into comparatively pure masses, while the secondary ore is much more amenable to smelting.

The oxidation of lead ores was well shown at Leadville, where the 'sand carbonate' and the 'hard carbonate,' accompanied by from 20 to 70 oz. silver per ton, were of great extent and value. Masses of similar ore, often extending to considerable depths, are a feature of the Sierra Mojada and Santa Eulalia mines, in Mexico. In these districts and in many others, the chief factors determining the alteration have been the soluble nature of the limestone country-rock, and the comparatively arid climate with slow erosion, which resulted in deep oxidation.

Calamine ores, formed by the removal of blende from the upper portions of veins, and re-deposition of the ore with more or less replacement of limestone or similar rocks, embrace some most valuable zinc deposits, such as those of Iserlohn in Prussia, Raibl in Carinthia, Upper Silesia, Spain, and many of the Belgian and Westphalian deposits. At Aschen, secondary calamine extends to a depth of 300 ft., where it gives place to blende. As a rule, calamine deposits show a preference for dolomite, owing to the greater porosity of that rock. As a result of the ready solubility of zinc ore, the upper portions of lead-zinc veins show an impoverishment of blende, accompanied by a relative enrichment of galena, while in the unaltered portions of the veins, blende may be the predominating ore.

Secondary silver ores have been a striking feature of most great silver-lead districts. Thus bonanzas of haloid ores are characteristic of desert regions, and were a remarkable feature at Broken Hill, where the gossan was deep, and at Santa Eulalia. Rich complex sulphides, formed in the zone of cementation were equally important at Neihart, Montana, and at Aspen, Colorado. In the Smuggler and Mollie Gibson mines of the latter district, rich polybasite ores with native silver occurred to depths of from 500 to 900 ft., in connection with cross-faults, and these secondary shoots were the main source of wealth of the two mines mentioned.

The secondary enrichment of argentiferous galena has a bearing on the loss of silver in the wet concentration of lead ore. Unaltered galena shows generally, under the microscope, no recognizable silver mineral, the silver being probably in a state of combination with the sulphide. Ore, on the other hand, that has been altered or enriched in its silver content, shows abundant fine threads of native silver following the cleavage-planes of the mineral. The occurrence of such ore may account for the notable loss of silver during dressing, much of the silver, freed by crushing, going off in the finest slime. The problem merits further examination at mines where highly argentiferous galena is worked and dressed.

Silver. The silver supplies of the world are obtained from silver-cobalt ores, silver-lead ores, and silver-gold ores. The alteration of these types is considered under the head of the respective associated metals. In general, native silver and haloid ores occur in the zone of oxidation, and complex silver sulphides in the zone of cementation beneath. Secondary silver ores have furnished some of the biggest

bonanzas in the history of metal mining; they are most characteristic of arid regions, where oxidation extends to a considerable depth, as at Broken Hill, and in the mines of Chile, Mexico, and the Great Basin. The abundance and value of haloid ores of silver in arid climates is a feature of great economic importance, and emphasizes the part played by climate in secondary alteration. It has been attributed by R. A. F. Penrose[6] to the salinity of the ground-water in such regions, and Charles R. Keyes[7] has referred cerargyritic ores to the presence of salt carried by wind-blown dust in these districts.

Gold. It is significant that practically all the world's great gold mines at the present day owe none of their value to enriched ore, but have depended upon primary ore persistent in depth. Mines and districts that thrived on secondary bonanzas have been short-lived, and have been scenes of disastrous booming and speculation, so that the secondary alteration of gold ores has often done more harm than good to mining. In the oxidized zone, the gold is freed from association with refractory sulphides and frequently becomes coarser by accretion. While these processes make extraction easier, they have also been the cause of failure, small concerns having been unable to treat the ore or save the gold from the deeper unaltered ore by means of unsuitable plant, only fitted for the outcrop ore. A notable effect of secondary alteration has been to raise the tenor of the bullion in the oxidized zone, as well as in the alluvium, by solution and removal of silver. Thus, at Mathinna, Tasmania, the alluvial gold has a fineness of 953.5, the vein-gold to the 360-ft. level is 900 to 955 fine, and at 1000 ft., 850 to 950. At Waihi, the gold of the primary ore is 645 fine, while Coromandel gold on the same field, which has been largely enriched, has a fineness of 750 to 800 per thousand.

Kolar, the Transvaal, and Kalgoorlie are three instances of localities where all the mines owe their success to unaltered ore persistent to a great depth. Secondary alteration has played only a small part in these cases, except perhaps at Kalgoorlie, where the occurrence of rich patches of oxidized ore, passing down into lean ore, led to the collapse of several concerns in the early days of the district.[8]

The great geological antiquity of the lodes, the subsequent metamorphism of the rocks that has rendered them highly resistent to weathering agencies, the dense quartz gangue, and the 'tight' unfissured structure of the country, are the chief factors hindering superficial alteration in these three districts.

Another great group of goldfields is the grano-diorite group, with which are associated the chief alluvial districts. The deposits occur along the older mountain chains of the Urals, western North America, eastern Australia, and the south island of New Zealand. They have been subjected to prolonged and vigorous erosion in temperate or cold climates, with the result that denudation has proceeded faster than the chemical processes, and a large portion of the valuable content has been removed, and concentrated in placer deposits. The outcrop ore of the lodes is practically unaltered, and the ground-water level, though shallow, is commonly deeper than the range of oxidation. In most of these districts the economic value of the lodes depends upon the unaltered ore. If this extend deeply, as at Bendigo, a long-lived industry is assured. Elsewhere the lodes carry rich patches near the surface, succeeded below by lean ore occupying the roots of highly denuded veins, as in Otago, New Zealand. In some deserted parts of Otago veins have been stoped from the surface to the ground-water level, a depth of from 20 to 40 ft., and rich patches mined, while the primary ore beneath has been left almost untouched. Whether alteration plays any important part in these grano-diorite regions is, however, largely dependent on climate and topography, that is, on the rate of erosion. Thus the ores of Rossland and of the Alaska Treadwell are practically unaltered at the surface. On the other hand, at Charters Towers, where the climate is arid and the surface flat, oxidation, with enrichment, has occurred to depths of 200 and 300 ft., and Mount Morgan, under similar climatic conditions, was once the world's greatest gold mine, owing to the effects of deep oxidation (180 to 300 ft.) in freeing the gold from the pyritic gold-copper ore of the lower zones. There also, the zone of cellular oxidized gold ores was succeeded by a prominent zone of secondary gold and sulphide ore.

A distinct type of deposit embraces the gold-silver veins of Tertiary age, associated with andesites or similar volcanic rocks. These lend themselves readily to alteration and enrichment, owing to the thermal alteration and ready decomposition of the enclosing rock, and to the frequent occurrence of the veins in areas of disturbance and fissuring, whereby ground-waters may circulate to great depth. In these districts the influence of climate is often strikingly displayed. The primary ore is commonly high in silver, and oxidation processes raise the tenor of the bullion, and frequently form silver bonanzas.

An instructive comparison is afforded between the Thames and Waihi districts of New Zealand. At the Thames, bonanzas occurred to a depth of about 500 ft. These were intimately related to the occurrence of cross-faults, and were probably largely of secondary origin. In depth, the veins become lean, so that prospects are not bright. At Waihi, on the other hand, though oxidation extends to a depth of 500 ft. beneath the outcrop, there is little or no enrichment, and the gold in the lodes is almost wholly original. The Mexican mines show effects of enrichment closely dependent on climatic conditions. Thus in the El Oro district, the ground-water level is deep, and the San Rafael lode has an extensive zone of oxidation, in which the proportion of gold to silver in the ore has been raised from 1:15 to 1:6. At Pachuca the oxidized zone carried free gold, and horn-silver, while the zone of sulphide enrichment beneath contained corresponding bonanzas of silver sulphides. In Nevada, similar conditions obtain. Goldfield owes practically all its importance to rich irregular ore-shoots in the oxidized zone. The ground-water level

[6] *Journal of Geology*, Vol. II, p. 314.
[7] *Economic Geology*, Vol. II, 1907, p. 774.
[8] H. C. Hoover, *Trans. Amer. Inst. Min. Eng.*, Vol. XXVIII, 1898, p. 758.

here (150 to 200 ft. deep) is shallow for an arid region. At Tonopah, oxidation reached a maximum depth, on the Mizpah vein, of 700 ft., and the oxidation zone has been characterized by silver chlorides, together with native silver and pyrargyrite. Oxide and sulphide ores are more or less intermixed, the two zones not being sharply separated. The groundwater level is extremely irregular owing to complex fissuring, one shaft being dry to a depth of 1100 ft. The Colorado goldfields of this type are mostly in regions of bold topography and heavier rainfall, with consequently more rapid erosion, and enrichment is of minor importance. At Cripple Creek there is no evidence of enrichment either in the oxidized ore, which extends to a depth of 200 to 400 ft., or in the telluride ore beneath; nor is there any enrichment at the Camp Bird, which is at a high altitude in a region subject to snowslides. A question of much practical importance is the subject of telluride enrichment of gold ores, corresponding to sulphide enrichment. The question has been raised by Malcolm Maclaren,[9] but no very definite evidence has so far been forthcoming.

ELECTROLYTIC COPPER REFINERY

The method of designing an electrolytic copper refinery may be illustrated by the following figures for a 12-ton plant. According to European practice one ampere-hour of current will deposit 1.183 grams of copper. One ounce equals 28.35 grams, and in a 12-ton plant the deposit of copper should be:

$$\frac{12 \times 2000 \text{ lb.}}{24 \text{ hours}} = 1000 \text{ lb. per hour.}$$

hence $\frac{1000 \times 16 \text{ oz.} \times 28.35 \text{ gm.}}{1.183} = 383.432$ ampere hours.

If the whole work has to be accomplished in one plant and plans for 90 vats in three series of 30 each be adopted, then the generator would have to furnish:

$$\frac{383.432}{90} = 4260 \text{ amperes.}$$

The voltage required per vat should not, in a well designed plant, exceed 0.6; but allowing for impurity of the anodes and other local conditions 0.8 will be a safe maximum. For 90 vats, then, $90 \times 0.8 = 72$ volts, will be needed, and $72 \times 4260 = 306{,}720$ watts $= 411$ horse-power to deposit 12 tons per 24 hours, or 34.25 hp. per ton as a maximum figure. But, as noted above, a voltage of 0.6 per vat should be ample under perfect conditions, and if this figure be adopted $90 \times 0.6 = 54$ volts will be needed and $54 \times 4260 = 230{,}040$ watts $= 308.3$ hp. to deposit 12 tons or 25.7 hp. per ton of copper deposited.

Suppose a current density of 12 amperes per square foot anode and cathode surface be figured, and for a generator maximum figures, 411 hp., be taken, with 10% added for loss in efficiency, the total will then be 452 hp. which, divided among three generators of 151 hp., calls for 150 hp. each. Assuming 12 amperes current density to be correct, $\frac{4260}{12} = 355$ sq. ft. anode surface will be needed in each vat. This may be taken as 360 sq. ft. in round numbers. Allowing a superficial area of 8 ft. per anode, 45 anodes $\frac{360}{8}$ will be needed in each vat. Figuring the size of the anodes to be 16 by 36 in., will just give 8 sq. ft. area for both sides. Anodes should be made about one inch thick, and should have a lug cast on each with a hole suitable for a hook. The width of a vat depends upon how many anodes are placed in it and connected on each single positive conductor bar. Suppose three to be arranged on a bar, and a 2-in. space be left between them, with 3 in. between the anodes and the sides of the tank, then the width of the tank will be 58 in. Dividing the 45 anodes by 3 gives 15 as the number of rows of anodes. A space of 2 in. should be allowed between the electrodes, and as there should always be one anode between two cathodes, it follows that there must be in this case 15 rows of anodes and 16 rows of cathodes. Fifteen rows of anodes, 1 inch thick equals 15 in.; 16 rows of cathodes, ⅛ in. thick equals 2 in., and 32 spaces of 2 in. equals 64 in. These added make the total length of a vat, 81 in. Allowing 10 in. space below the anodes will give a depth of 46 in. The size of the vat therefore should be 7 ft. long by 5 ft. wide by 3 ft. 10 in. deep.

At each series of vats the positive terminal of the generator is connected with two copper bars, well insulated, resting on the vat. Slightly elevated above these two bars are placed two negative copper bars, which at the end of the vat are bent and extended into the next vat as positive bars in line with the terminal bars in the first vat; and so on from vat to vat until the end of the series, where the last pair of bars is connected with the negative terminal of the generator. Iron cross-bars from which the anodes are suspended rest on the positive conductor bars, and iron bars supporting the cathodes rest on the slightly elevated negative conductors. The vats are filled with the solution $H_2O + CuSO_4$, and it is important to have this solution circulate both rapidly and quietly in order not to disturb the mud collected. All the anodes and cathodes in a vat should be raised and lowered in a battery and transferred by help of a traveling crane or overhead crawl. The anodes may be cast in the copper converter plant in sizes as given above, transferred to the electrolytic refining plant, and placed in the vats. The cathodes should be of the purest commercial sheet-copper of the same sizes as the anodes. The electrolytic process transfers all the copper in the anodes, less the impurities, to the cathodes, and the copper accumulated on the cathodes varies but a small fraction from 100% pure. The plant should, by preference, be housed in a steel building on stone or on a concrete foundation.

[9] 'Gold,' London, 1908, p. 114.

Exports of iron and steel manufactures in the past fifteen years exceeded imports thereof by $1,400,000,000, while in the fifteen years immediately preceding the imports exceeded exports by $300,000,000. Meantime the United States has become by far the world's largest producer of pig iron, domestic production having advanced from 4,000,000 tons in 1885 to 25,750,000 in 1909, and exceeding in that year the combined product of her principal rivals, Great Britain and Germany. This large excess of exports represents a development in the domestic industry brought about in comparatively recent years.

Boise Basin, Idaho

By W. A. Scott

The name 'Boise Basin' is applied to an area of nearly 300 square miles in Boise county, Idaho, which is drained by Moore, Elk, Grimes, Wolf, and Granite creeks, the waters of which flow southerly into Boise river. The basin, as outlined by the contour of this drainage system, is nearly fan-shaped. Idaho City is situated at the confluence of Elk and Moore creeks, Centerville and Pioneerville are on Grimes, Placerville is on Wolf, and Quartzburg is in Granite creek canyon. Idaho City is close to the southeastern rim of the basin, Quartzburg is at the western extremity, with Centerville in the central part.

Placer Mine on Grimes Creek, Boise Basin, Idaho.

From 1863 to 1875 there was intense activity in placer mining on these creeks, and the production of gold was such as to give Boise Basin a high place in the annals of this kind of mining. Those years of bonanza production have been succeeded by thirty years of steady uneventful work on the same creeks and their adjacent banks, and while there has been, undoubtedly, a steady decline in the annual clean-up of placer gold, the production today is relatively good. Much of the tailing that resulted from hydraulic work has been re-worked by dredging, and some of the dredging operations now in progress are in virgin ground. The period of hydraulic work with giants is limited to about four months, as the water supply usually runs short in July. This is especially true as to Moore, Elk, and Wolf creeks, but the season on Grimes creek is longer.

The Boston & Idaho Gold Dredging Co., for which W. H. Estabrook is manager, is operating one dredge of the Risdon type, having 5-cu. ft. buckets, open-connected, handling about 2000 yd. per 24 hours, digging to a depth of 20 to 30 ft. This is being operated on Moore creek, seven miles down stream from Idaho City. The same company is having a new dredge built on Elk creek, half a mile up stream from Idaho City, which will have a chain of 13-cu. ft. buckets, close-connected, giving as great capacity as that of any dredge in the country. It is being built by the Yuba Construction Co. The Elk creek material to be handled by this dredge was sluiced in early days. This company owns the electric power-plant, situated on Payette river, below Horseshoe Bend, current from which is transmitted to all places in Boise Basin where power is needed for dredges, mills, and hoists.

The White Quartz Mining Co., made up of Ohio and Pennsylvania men chiefly, purchased the H. L. Woodburn placer property last April at $125.000, and in 1909 purchased the Mann & Hanson holdings. These purchases give the new company all of the Gold Hill placer grounds, including the former Plowman placers. It comprises the area between Bear run and Lincoln gulch, a part of it facing Elk creek; as well as all water rights and ditches controlled by the former owners. There are said to be 100 miles of ditches by which water is taken from Moore and Elk creeks. The Mann & Hanson ditch, which carries 500 in. of water, is to be enlarged to carry a much greater volume; the Plowman ditch is also to be made larger. The workable gravel of the Gold Hill area has a depth of 60 to 70 ft. At present four giants are being operated in two pits facing Elk creek. C. F. Herrick, by whom the purchases were made, is the company's manager.

The Centerville Mine & Milling Co. has an extensive area of placer ground on Grimes creek, both

above and below Centerville. It consists of placer tailing in the bed of the stream, and both worked and unworked ground on the adjacent banks and benches. It has been demonstrated that there is here a considerable yardage of virgin ground covered by tailing. The company has hydraulic giants at work on tailing and new ground in the stream, and on the higher benches. The work on the creek is supplemented by a hydraulic elevator by which the material is raised from the bedrock to the sluiceway, a height of 17 ft. It has been known for several years that monazite in liberal quantity is disseminated throughout the placer ground of this creek, not only in the creek bed but the material of the banks and bluffs. It is found slightly concentrated close to the bedrock in the tailing deposited by giants and dredges. The company, under the management

of S. K. Atkinson, has erected a milling plant at Centerville for concentrating this hydraulic tailing and for separating the monazite from the magnetite, silica, and other minerals. By screening and table-concentration a product is obtained which is said to contain 25% monazite. This is first dried in a revolving dryer, then passed through a rotating magnetic machine of low intensity by which the magnetic iron particles are taken out, after which it passes through the field of a magnet of greater intensity by which particles of ilmenite and garnet are taken up; and finally the residue is passed through a still more powerful magnetic separator which takes up the monazite, leaving a non-magnetic residuum consisting of zircon and silica. The monazite concentrate thus obtained is said to be 90% pure, and carries 5% thorium, the extraction of the latter being the ultimate object of mining and milling the monazite-bearing sand. The magnetite and zircon, however, are considered valuable by-products. The milling plant contains an elevator, revolving screens, 12 Wilfley and Card tables, a dryer, and five electromagnetic machines, and has the capacity of 100 tons per day. Additional equipment to be provided is to consist of arrangements for conveying the material from the bedrock of the stream to the mill by hydraulics. The magnetic separators in use were designed by members of the company's staff. These monazite-bearing deposits resulted from the disintegration of the granitic bedrocks, which contain some pegmatite, the monazite being closely associated with the latter. It is estimated that the virgin ground contains from 0.01 to 0.1% monazite; and that in the tailing the latter is more concentrated and runs from 0.1 to 1%. The new ground, therefore, is being worked for placer gold by the ordinary methods, and the plan is to concentrate the tailing, both old and new, for the recovery of monazite.

The monazite production of the United States for the year 1908 was 422,646 lb., worth $50,718 at 12c. per pound; and the imported article, which pays a high duty, for that year amounted in value to $173,239. The domestic product heretofore has been mined in the Carolinas, the foreign product in Brazil, the importers being Germans mostly. Thorium nitrate, obtained from monazite, is largely used in the manufacture of incandescent gas mantles. The Centerville M. & M. Co. has expended $150,000 thus far in equipping the property.

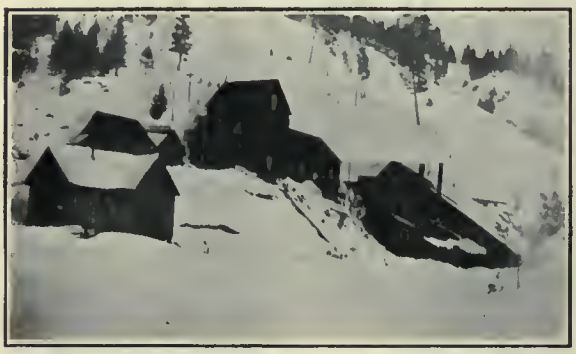
The Moline Mining Co., for which E. F. Blaine is manager, has a 5-cu. ft. Risdon dredge at work on Fall creek, close to its confluence with Granite creek. The latter empties into Wolf creek below Placerville. This dredge, which has a record of successful operation, is performing its fifth season's work and is in direct charge of Bird Will, formerly of Oroville. In this period about 80 acres have been dredged on Granite and Fall creeks. After passing through a deposit of tailing the fore part of the season the boat is now pushing up Fall creek in virgin ground, which runs from 35 to 40 ft. deep. The dredge handles about 1200 yd. per day and operates by steam-power, using wood as fuel.

The Boise Basin Hydraulic & Power Co., concerned in which are Albert Burch, of San Francisco; M. A. Folsom, of Spokane; E. S. Robinson, of Placerville; and others are interested, has 19 placer claims lying between Wolf and Ophir creeks, east of Placerville. The company has hydraulic giants in operation in two or three pits, and usually operates from the latter part of March to July 15. Mike Leary, his sons, and associates, have been hydraulic mining on Wolf creek, at Placerville, for forty years, and they are still operating profitably. They have other ground on Granite creek. A 14-mile ditch from Granite creek carries the necessary water to their gravel banks at Placerville.

The Columbia Mining Co. has locations covering a lode parallel to that of the Gold Hill and Iowa. Its vein is opened by a 250-ft. shaft on the west side of Granite creek, and by three adit levels on the oppo-

site side, all these openings being on the vein. A mill was built last year which is idle at present. It is equipped with a crusher, Chilean mill, plates, and tables, and the plan is to cyanide the concentrate. I. H. Friar, the manager, states that arrangements are being made to resume work. This property is known locally as the Last Chance.

The Golden Age mine, owned by Spokane and Portland people, is situated at Grimes Pass, six miles northeast of Pioneerville. There are two veins which are opened by an 1800-ft. cross-cut that gives a depth of 300 ft. Considerable driving has been done in ore on this level. A winze is to be sunk on the main vein from the cross-cut level. The vein varies in width from 1 to 12 ft., and is said to have an ore-body that averages 30 in. wide. The ore contains free gold and sulphide material. A 15-stamp mill, equipped with plates and tables, is operated by water-power, there being two Pelton wheels having the pressure of 110-ft. head of water from Grimes creek. E. R. Abernethy is superintendent and there is a force of 30 men on the property. The Golden Rod M. Co., owning the Mineral Hill property north



Pioneer Shaft, Gold Hill Mine, Quartzburg, Idaho.

of Placerville, has considerable development, which shows a series of small veins in altered granite and porphyry, the ore containing gold and silver in sulphide of iron, but with some free gold, and bismuth. The mill, which has a crusher and Chilean mills, is to have a tube-mill and filter-presses added, to adopt the all-slime process. A. C. Gallupe, who has charge, states that arrangements have been made to start work again.

Quartzburg is the home of the Gold Hill and Iowa mines, now consolidated under the ownership of the Gold Hill & Iowa Mines Co., for which E. E. Carter is manager and W. L. Bowron is superintendent. The two original mines were on a strong northeast vein, which stands almost vertically in a porphyry dike, cutting through a granite country. The ore occurs in shoots from 7 to 30 ft. wide, and 30 to 100 ft. long; within these shoots are chimneys and lenses. The vein boundaries are not in all places sharply defined. The gangue is largely porphyritic, but it contains a great many stringers of quartz. It carries gold in free state, and in association with stibnite, both crystallized and massive. It carries 2 to 3% iron and a still lower percentage of lead and zinc. The principal work is carried on through a 3-compartment shaft, which is now 500 ft. deep. The main workings are on and above the 400-ft. level; but driving is to begin from the 500-ft. station to get at the ore beneath the old workings. The mill which is in operation is equipped with 20 stamps, a Lane mill with amalgamating plates below it, six Bartlett tables, three vanners, and two Pachuca agitating tanks. A Richards pulsator classifier is in use between the plates and tables. The table and vanner concentrate, which is about 50 mesh, is elevated to the Pachuca tanks for agitation and cyanidation. The recovery on the plates is said to be 55% of the total saving. The mill, air-compressor, and double-drum hoist are electrically operated, this power costing the company $5.40 per horse-power per month.

The Idaho-Elkhorn Mining Co., managed by E. F. Fitzhugh, owns part of the old Elkhorn group and has a bond on the other part. This is an old mine which was active and productive from 1865 to 1870, having produced at that time half a million dollars. It is at the head of Elk creek, 12 miles northeast from Idaho City. There is a 1500-ft. cross-cut that strikes 250 ft. below the old workings. The formation is faulted, making a complex vein system. However, the lead has been found by driving from the old cross-cut, and drifting thereon is in progress. The ore in the old workings is a gold-bearing quartz, and the vein is in granite.

The Edna Mines Co. has a developed and producing mine close to the north fork of the Boise river, 22 miles northeast from Idaho City. While this property is outside of Boise Basin, all the travel and freight destined for the Edna is by way of Idaho City, which is 36 miles north of Boise. The principal vein of the Edna consists of a fissure in a granite formation, having a width of 7 to 14 ft. It is opened to a depth of 340 ft. by a 1400-ft. cross-cut, and by 1000 ft. of driving on the vein; also by a 3-compartment raise from that level to the surface whereby the stopes were opened. A 100-ft. winze was sunk on the vein from the main level. The ore runs 98% silica and carries chloride and sulphide of silver, accompanied by some gold. Charles R. Watson, manager for the company, states that the ore contains $10 in silver to $1 in gold. The iron in it amounts to less than 1%, and copper and lead about the same. The ore runs 22 oz. silver and $2 gold per ton. The new mill, now nearly finished, is expected to be in operation by July 1. It is equipped with a Blake crusher, 11 by 15 in.; 8 Nissen stamps, making two 4-stamp batteries, with mortars having 10-mesh screens. The stamp-crushing is to be in cyanide solution. The pulp will pass from the batteries to a double Dorr classifier, the slime from the latter to six 8-ft. Callow tanks. The overflow from the tanks goes to the mill sump; the dewatered slime passes to one of a series of Gordon tanks, making a continuous process. The Dorr sand is reduced to 150 mesh by an 8-ft. Hardinge conical mill, after which it passes by a launder to the Gordon agitating and aerating tanks, which are each 15 ft. high, 20 ft. diam. The slime solution in those tanks is drawn off to Moore filters having 5280 sq. ft. of filtering surface. The solution is passed to zinc boxes for precipitating the metals. According to 250 tests which were made, the cyanidation of these ores will require 3 lb. cyanide to the ton of ore.

Iron Ores of California

By E. C. Harder

*Iron-ore deposits are abundant in different parts of California, yet until recently no ore had been mined. The only iron-ore furnace in the State is an experimental Heroult electric furnace installed in 1907 by the Noble Electric Steel Co. at Heroult, on Pit river, Shasta county, and operated intermittently in 1907, 1908, and 1909. During 1909 a commercial furnace was erected. The ore used is mined in the vicinity of the plant. Besides the Noble furnace there are only four iron-ore furnaces in the Western States—the Minnequa coke furnaces at Pueblo, Colorado, consisting of six stacks; the Irondale charcoal furnace at Port Townsend, Washington, consisting of one stack; the Black Sand & Gold Recovery Co.'s electric furnace at Hood River, Oregon, and the Oswego charcoal furnace at Oswego, Oregon, consisting of one stack. The Oswego furnace has not been active since 1894 and the electric furnace at Hood River is only in an experimental stage. The Pueblo furnaces, however, have been operated regularly for many years, their ores being obtained largely from Wyoming, Colorado, and New Mexico. The furnace at Port Townsend has been active intermittently, its ores coming from Texada Island, British Columbia, and from Washington. No California ore has been used in any furnace outside of the State.

The principal iron-ore deposits of California are the Pit River or Redding deposits, Shasta county; the Gold Valley deposits, Sierra county; the Minaret deposits, Madera county; the Iron Mountain, Cave Canyon, Providence Mountain, and Newberry deposits, San Bernardino county; and the Eagle Mountain deposits, Riverside county. Of minor importance are the Patamocas or Beegum deposits, Tehama county; the Newtown and Indian Springs deposits, Nevada county; the Hotaling deposit, Placer county; the Detert deposit, Calaveras county; the Mount Raymond deposits, Madera county; the Perfumo Canyon deposit, San Luis Obispo county; and the Owl Holes, Kingston Range, Garlic Springs, and Iron Age deposits, San Bernardino county. Numerous other small deposits are known. The Minaret deposits, situated near the summit of the Sierra Nevada, are said to be the largest in California, and perhaps in the West. Of nearly equal size are the Eagle Mountain deposits, situated near the boundary of the Mohave and Colorado deserts; all the rest are much smaller. The only ores which have been worked with the intention of producing pig iron are the Hotaling deposit, operated some years ago unsuccessfully on account of the high cost of fuel, and the Pit River deposits, operated intermittently for the last few years to obtain ores for use in the Noble electric furnace. Practically, therefore, the iron ores of California are untouched.

The Perfumo Canyon iron-ore deposit is in San Luis Obispo county, about five miles south of west from San Luis Obispo, in the San Luis or Los Osos mountains. It consists of a nearly vertical bed of limonite interlayered with dark shale and sandstone of the Franciscan formation (Jurassic). The bed strikes in general a little north of west and is said to be traceable for more than a mile, but was followed by me through only about half of its extent. Its thickness varies from 8 to 12 ft. The ore is largely a dark brown or black glossy limonite, finely banded and laminated parallel to the strike of the bed. Numerous fractures run through the bed, so that the ore breaks up into small variously shaped blocks with plane surfaces. This condition is characteristic of the bed throughout its extent. The following are analyses of the ore and the highly ferruginous shaly sandstone.

ANALYSES OF IRON ORE AND WALL ROCK FROM PERFUMO CANYON, CALIFORNIA

(Dickman & Mackenzie, analysts, Chicago)

		Iron, %	Phosphorus, %	Silica, %
1	Ore outcrop near creek, 11 ft. of ore.	44.80	0.500	15.41
2	Ore outcrop 2000 ft. southeast of No. 1	47.60	0.530	11.20
3	Ore outcrop 3000 ft. northwest of No. 1	46.10	0.510	13.10
4	3 ft. of ferruginous shale underlying No. 1	16.30	....	....
5	Ferruginous shale, average	13.30	....	....
6	Ferruginous shale, selected	13.40	....	....

It seems clear that the iron ore of Perfumo Canyon is an original sedimentary deposit formed during an interval in the deposition of the inclosing sandstones and shales. It is probably of the nature of a bog deposit which has been consolidated during the compression and folding of the accompanying strata. On the assumption that the bed has a fairly regular thickness of 10 ft. there would be a great tonnage of low-grade ore left in the ground. For commercial purposes, however, it must be considered that the bed may vary in thickness beneath the surface, may pinch out altogether for long distances, or may grade into ferruginous standstones at slight depths. A depth greater than 100 ft. should not be assumed without exploration, and this would reduce the probable available quantity to a few hundred thousand tons of low-grade ore, which is a fairly safe commercial estimate.

Several small deposits of brown iron ore occur in Calaveras county as replacements in slate or schist. They are in the central part of the Mother Lode district, in the western foothills of the Sierra Nevada. There are three localities at which iron ores are known in Calaveras county, one and one-half miles northeast of Valley Springs, half a mile north of Esmeralda, and one mile north of Murphy. All the bodies are small and consist of low-grade ore, so that they are of little or no commercial importance.

The Hotaling iron-ore deposit is six miles north of Auburn and three and one-half miles northwest of Clipper Gap, Placer county. The workings, consisting of several trenches, pits, and shafts, are on a small wooded knoll extending southwestward from a higher ridge. One shaft has an engine house in connection. Ore was mined and smelted here some

*Abstract from Bull. 430-E, U. S. Geol. Survey.

years ago and considerable ore is still in the dumps. A band, perhaps several hundred feet wide, of fine-grained basic igneous rock, probably diabase, crosses the knoll in a northwest-southeast direction. Northeast of it, forming the higher ridge, is a mass of granodiorite; to the southwest, on the slope of the knoll, are sediments of the Calaveras formation (Carboniferous), here largely quartzite. The granodiorite is later than the diabase, and both are later than the Calaveras formation. The iron ores occur at the contact of the diabase and the quartzite and within both formations, though more generally in the diabase. The ore is magnetite, both fine grained and coarse grained, and with it are associated a large number of minerals, such as garnet (andradite), epidote, pyroxene (augite), amphibole (anthophyllite), calcite, pyrite, chalcopyrite, and quartz. The workings extend along the contact of the quartzite and diabase through a distance of 150 or 200 ft.,

Map of Portions of Southern California, Nevada and Arizona Showing Iron Ore Deposits

and the extent of the ore beyond this in either direction is problematic. Most of the ore is thoroughly intermixed with the metamorphic minerals and later vein minerals and is therefore of low grade. The orebody is small and as a whole of low grade.

The Iron Age iron-ore deposit is six miles east of Dale and a mile or two north of the boundary line between San Bernardino and Riverside counties, in a barren desert region. It is in the eastern part of a range of bare mountains extending east and west along the boundary line and connected by an area of low hills with the Pinto mountains to the southeast. The deposit may be reached from Dale by a direct trail through the mountains or by a circuitous wagon-road along the edge of the desert area to the north, a distance of ten or twelve miles. The Dale pumping station, about six miles north of Dale, is the nearest watering place, and there is no other spring or well within a radius of twenty miles. The mountain range in which the iron ores occur consists of intrusive dioritic, granitic, and syenitic rocks of varying texture. In the southern part of the Pinto mountains metamorphosed sediments are associated with these rocks, but elsewhere no sediments occur.

The Iron Age iron ores are largely hematite altered from magnetite, in the form of veins cutting intrusive granite and granite porphyry. Metamorphic minerals, chiefly garnet and epidote, are locally associated with the ore and rocks. The principal iron-ore veins occur over an area about half a mile square, the larger veins, on account of their resistant nature, forming the summit of a large hill. Several small veins occur in the area between the Iron Age deposit and Dale. The ores are very pure and of high grade, but the veins are not of sufficient extent to make the deposit especially attractive commercially. The iron-ore veins composing the Iron Age deposit undoubtedly originated from hot deep-seated solutions, being formed after the cooling and consolidation of the igneous rocks in which they occur.

CLASSIFICATION OF PETROLEUM AND NATURAL GAS FIELDS BASED ON STRUCTURE

By Frederick G. Clapp

*The main divisions of the classification proposed are as follows: (I) Anticlinal and synclinal structures: (*a*) strong anticlines standing alone, (*b*) well defined anticlines and synclines alternating, (*c*) monoclinal slopes with change in dip, (*d*) terrace structures, (*e*) broad geanticlinal folds. (II) Domes, or quaquaversal structures (Salines). (III) Sealed faults. (IV) Oil and gas sealed in by asphaltic deposits. (V) Contact of sedimentary and crystalline rocks. (VI) Joint stacks. As examples of subclass I (*a*), the fields on the Eureka-Volcano-Burning Springs anticline of West Virginia and certain California fields are given. In subclass I (*b*) are placed most of the fields related to anticlines and synclines in the Appalachian province, the Caddo field of Louisiana, the Coalinga and Los Angeles fields of California, and the Burma and other well known fields in other countries. The majority of the oil and gas pools of southeastern Ohio belong in division I (*c*), or in I (*d*), which is an exaggerated form of I (*c*). The best example known of subclass I (*e*) is stated to be the extensive field on the Cincinnati anticline in Ohio and Indiana. Class II includes the fields of the gulf coastal plain. Class III is exemplified by certain pools in the Lompoc field and perhaps other fields of southern California. Class IV is somewhat hypothetical so far as oil and gas accumulations of economic value are concerned, but it may be exemplified by the pitch lake of Trinidad. Class V is known to exist in the Province of Quebec and to some extent in northern New York, where natural gas is found in the arkose zone of the Potsdam sandstone resting on prominent knobs in the underlying crystalline rocks. Class VI was added after the discussion in accordance with a suggestion by M. R. Campbell. An example of it is a part, at least, of the Florence oilfield in Colorado.

*Proposed in a paper read before the Eng. Soc. Western Pennsylvania and the Wash. Geol. Society.

Mine-Rescue Work

Now that the Bureau of Mines is about to begin work, attention is being sharply directed toward mine accidents and their prevention. Incidentally mine-rescue work and first-aid training for miners seem likely to receive some of the attention they long have needed. In the United States the work so far done has been mainly in the coalfields. The anthracite coal companies have taken the lead in systematically training their men in first-aid work, while the U. S. Geological Survey, through the Technological Branch, has done most important work in the study of explosions, and in mine-rescue work. Because of a limitation in the act making appropriations for this work, attention has been concentrated on accidents in coal mines. Under the new law these studies can be expanded to cover metal mines as well. That there is room for such expansion is clear to everyone familiar with the subject. While figures covering accidents in metal mines are notoriously inaccurate, it is clear that in many districts they rival in number those in coal mines, despite the greater frequency in the latter of dangerous gases.

The mine-rescue work of the Geological Survey grew out of attempts to determine the causes of coal mine explosions. In order to get at the facts it was necessary that the engineers should make prompt investigation of each accident, and this in turn gave them active and honorable part in mine-rescue work. A general testing laboratory has been equipped at Pittsburg and branch rescue stations have been established at Urbana, Illinois, Seattle, Washington, and Knoxville, Tennessee. So important and successful has been the work done at these stations that Congress has now appropriated money which will allow the establishment of nine more, and the General Assembly of Illinois has provided for three others. The Colorado Fuel & Iron Co., the Pittsburg Coal Co., and other corporations have opened stations of their own.

The equipment and work of such stations has been discussed by R. Y. Williams, the mining engineer in charge at Urbana, Illinois, in connection with plans for the new Illinois stations. From his paper, presented to the Western Society of Engineers, May 4, the following notes are condensed.

"The station building should contain a gas-tight room, 40 ft. long by 20 ft. wide and 10 ft. high. (Fig. 1.) The interior of this room should be fitted to resemble a mine and to afford opportunity for the practising miner to do work similar to that required in the event of an actual disaster. In a number of stations already built in this country, it has been the practice to divide this room longitudinally and to construct an overcast on one side, the aim being to present a passageway about the room, the travel over which would represent the journey of a rescue party through the entries of a mine. This room should be furnished with mine props and a frame consisting of four pieces of 6 by 8-in. timbers joined together in the shape of a square and tied with two iron rods, in which props may be set and capped with wedges; also brattice cloth, stretchers, and a canvas dummy filled with sand and sawdust so as to weigh about 165 lb. In order that the men may gain confidence in working in the presence of gas, sulphur candles may be burned in this room to form a choke-damp; charcoal may be fired in open salamanders yielding black-damp; hydrogen disulphide may be generated producing stink-damp, or ordinary dense smoke may be obtained by burning dampened excelsior. Adjoining the smoke room and separated from it by a glass partition, should be an observation room where visitors may sit and view the work of the miners. Here, too, the instructor may observe and record the performance of each member of the rescue squad. In this room there should be wall-cases in which the rescue apparatus may be hung

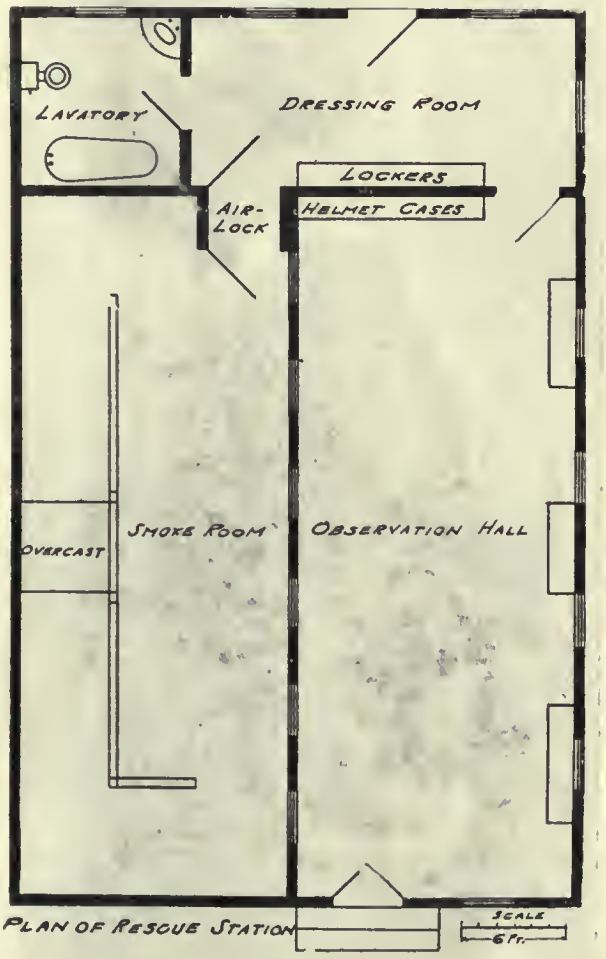


Fig. 1.

and protected from dust; there should be work benches to facilitate the cleaning of instruments and the charging of electric safety lamps; and a place to store the cases in which the apparatus is shipped. Back of the smoke room there should be a lavatory containing toilet, shower-baths, and lockers for the accommodation of the miners coming to the station for practice.

"The equipment of the station should include oxygen helmets, or other suitable breathing appliance furnishing a dependable supply of pure air, with the aid of which men may safely enter any kind of foul and most poisonous atmosphere in order to perform rescue work. Apparatus and supplies for recharging these machines, portable electric safety lamps with a convenient device for recharging, a supply of some standard make of oil-burning safety

lamps, and one or more resuscitating cases for use in reviving men overcome by the afterdamps of mine fires or explosions should be furnished. Special cases or trunks of convenient size for handling, in which the above apparatus may be quickly packed and safely transported to the scene of an accident are also necessary.

"The character of the training given should include a general study of the conditions that obtain during and after a mine fire or explosion, with special detailed reference to concrete cases. With these actual occurrences in mind, plans should be

Fig. 2.

discussed for sussessfully solving the problems according to modern rescue practice. The principles on which the machines used at the station are constructed and operate should be explained; and a thorough first-hand knowledge of the manipulation of the various forms of apparatus should be acquired by the miner. The actual training of the mind and body to do work similar to that required in the actual recovery of a mine and in the presence of deadly gases should be given by means of drills in the smoke room. In this way, men become acquainted with the possibilities and limitations of the machines, gain knowledge as to their own prowess as rescuers, and learn to work in squads under the leadership of one of their comrades. For mental and physical ability shown in the work, a certificate of competency should be awarded. This would tend both to keep up interest in the work of the station, and to be of especial value as a reference card when a disaster occurs.

"The advantages that obtain from such stations are in a large measure obvious. It often happens in an explosion that the ventilation machinery is thrown out of commission or totally destroyed. Also it is often necessary after an explosion to stop the fan to prevent a series of subsequent blasts and to control a mine fire by cutting off all ventilation. Previous rescue methods have afforded only a choice between two evils; either close the mine with concrete stoppings and leave it sealed indefinitely, or start the fan, send in the men and trust to luck, with the result of the loss of many lives and much property. With the introduction of modern practice, however, rescue work assumes a decidedly different aspect. With the aid of the breathing appliances, trained men may enter the mine at once with comparative safety and begin the task of recovery, without aid of air-supply from the fan. As the work progresses, each step may be taken with a complete knowledge of the situation gained from the careful reconnaissance of the helmet men. Not least among the advantages that accrue from the employment of rescue stations, is that in cases of emergency there are available squads of men trained for the undertaking, accustomed to working together and obedient to the commands of their leader. A further advantage is that such rescue stations may become centres for the dissemination of knowledge among the men. In addition to the usual studies and lectures, local institutes may hold their meetings in the observation hall of the station; and talks and demonstrations on first-aid work may be given by the town or company physician with a view to forming First Aid Corps similar to those that are meeting with such success in the anthracite fields of Pennsylvania.

"A station may be built for $5000, and equipped with a complete line of apparatus for a like sum, itemized as follows:

12 oxygen helmets, or other suitable breathing appliances.
12 portable electric safety lamps.
12 oil-burning safety lamps.
6 oxygen tanks or reservoirs.
1 oxygen pump.
2 oxygen reviving outfits.
200 potash cartridges.
1 chemical cabinet for gas analysis.
15 cases or trunks for transporting the above apparatus. Furniture, including chairs, tables, wall cases, etc., tools, and supplies.

"Three stations, as proposed, may be completely installed for $30,000. In charge of each of the central rescue stations there should be a man whose experience in coal mining has been large and varied—someone who can maintain the interest of the miners who visit the station, care for the apparatus, and keep the records. Over the entire rescue work, with power to purchase supplies, direct the course of training, and assume the entire charge in case of a mine disaster, there should be a man who is a mining en-

gineer by profession, one who has had experience in all phases of coal mining, including mine-rescue work, and upon who may be thrown with confidence the welfare of the whole proposition. Each operator should be asked to send a small number, say 4%, of his employees to the nearest of the central rescue stations at least twice a year for training. These men should spend at least three days at the station on each visit. In return for the operator bearing such expense for the safety of the lives of his miners, the men so trained should agree, in cases of emergency, to assist in the work of mine rescue, with the understanding that they are to receive only the 'inside wage scale' for time devoted. The central stations could be made of great value to both miners and operators."

In the work at Urbana and the other American stations a number of different types of helmet have been tried. The one most frequently used is the Draeger (Fig. 2), a German helmet supplied with compressed oxygen tanks and a device for precipitating the carbon dioxide breathed out by the wearer, the nitrogen being used over and over. With this helmet men can work in the most noxious gases as much as two hours. In Western Australia, where in the gold mines much attention has been devoted to mine-rescue work, the Vajen-Baden and Fleuss-Davis-Hall helmets are the favorites. They are lighter than the Draeger and are supplied with compressed air rather than oxygen but they only permit of one hour's work without renewal of supply. When account is taken of the time necessary for getting to and from the place of work, this is seen to be a serious limitation.

One of the facts which has been made most clear by the work so far done is that to fight fires and gas underground with the new apparatus, will require new tactics as well. In the recovery of the Majestic mine in Illinois, Mr. Williams cut off the endangered portion by air-locks and then, wearing a helmet, went into the gas-filled part of the mine and made an inspection which permitted the recovery of the mine without further accident. It was plainly apparent afterward that attempts by the old methods of bratticing and carrying an air current, would have resulted in serious disaster. In one of the Pennsylvania mines J. W. Paul, by making a quick traverse through the workings immediately after an explosion, was able to put out incipient fires and even to save lives.

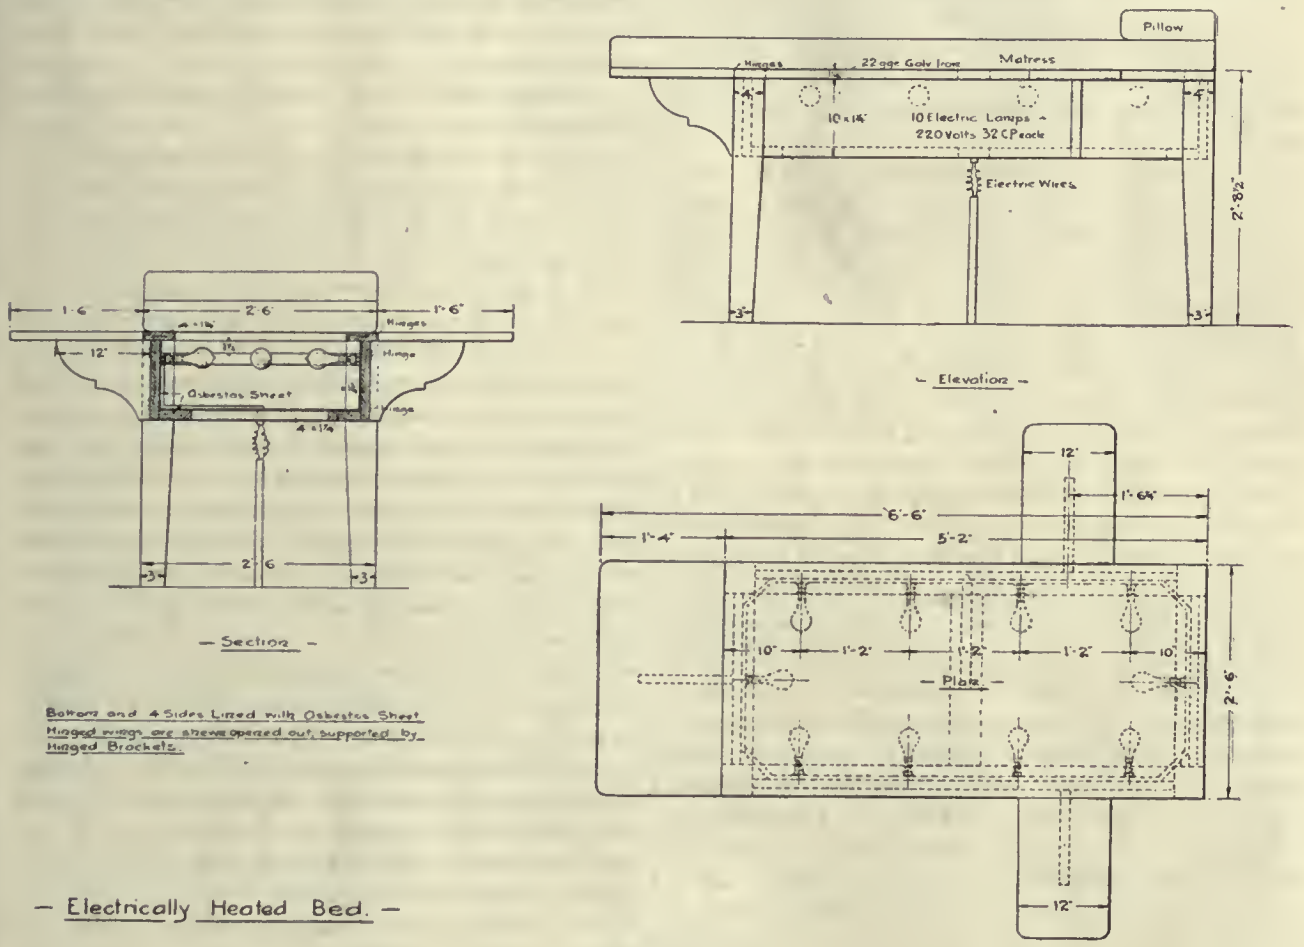

Fig. 3.

Not only are new tactics called for but trained men are needed. Scientific apparatus may be dangerous rather than helpful when placed in the hands of unskilled men. The new rescue stations will be especially valuable in training men. It is proposed that first-aid methods as well as other rescue work shall be taught. In Australia and Africa the importance of such work is recognized and at Kalgoorlie the St. John Ambulance Association has done much in aid of men injured in the gold mines. In 1906 when the work began on the goldfields, with the exception of a few obsolete stretchers at some of the big mines, practically no provision had been made for the proper handling of the injured. Since then casualty wards have been erected and equipped with up-to-date appliances, and on some of the mines a special ambulance corps is always at hand. Anyone familiar with

accidents underground knows how difficult it sometimes is to extricate a miner from beneath the fallen rocks, and it is in such cases that the rescue corps is of invaluable assistanee. After the rocks have been removed the patient is immediately treated for whatever injury he has received and then strapped in a Lowmoor jacket attached and brought to the surface in a vertical position.

The casualty wards are fitted with electrically-heated beds (Fig. 3) hot and cold water, medicine chests, splints, and bandages, and it is here that much can be done to relieve pain before the arrival of a doctor. The electrically-heated bed is a valuable acquisition to an accident ward, seeing that a man brought up from underground wet and cold can be placed between warm blankets immediately, if necessary. The beds are inexpensive and can be made at the mine.

The Association has given great attention to transport work and the mines are gradually being equipped with proper ambulances and litters. It has also instructed a number of men and maintains training quarters for the use of members. Lectures are given by medical men and every effort is being made to induce the mining companies to prepare to care properly for their injured employees. From statistics it is apparent that the majority of fractures that occur underground are simple and if those first on the scene of accident apply suitable splints, the possibility of a more serious fracture is prevented. The broken ends of the bone are so sharp that any attempt to remove the patient without first securing the limb in splints is likely to lead to serious injury. A good improvised method of splinting is to use parts of the side of a candle box or similar pieces of wood tied by means of handkerchiefs, braces, or string. Extreme cleanliness should be exercised in regard to wounds of every description as by thoroughly washing and treating the wound with some antiseptic the possibility of blood-poisoning is considerably lessened. This applies not only to large, but to small wounds.

The pamphlets published by the Mines Departments of Western Australia and South Africa fully describe the proper methods to be adopted when men are overcome by gases underground. The suggestions made by the writers of these pamphlets have been tested, and no difficulty has been experienced in treating bad cases. It has been found that the electrically-heated tables in use are of great assistance in restoring patients suffering severely from shock. Too much precaution cannot be taken in cases of men overcome by gas and the old idea of giving large quantities of alcoholic stimulants is dangerous. The brandy bottle which was so much in evidence in the early days has given place to readily prepared doses of sal volatile. In the United States but little has been done along these lines and it is expected that the new Bureau of Mines will point the way to effective organization by companies or by districts so as to decrease as much as possible injuries and loss of life. In Nevada, the Goldfield Consolidated Mines Co. has recently taken the matter up and has provided apparatus and planned systematic training on a large scale.

HYDRO-ELECTRIC POWER FORMULAE

James H. Wise

*Formulae for quickly determining approximate results in all branches of engineering work are quite essential not only for making rapid mental determinations, but for checking more precise calculations which are not infrequently of many operations and are thus subject to error. Knowing the quantity of water and static head in feet, four very simple rules for determining the hydro-electric output of a power-plant have been developed and are herewith also expressed as equations. It will be noted that three units of water measurement are embodied and the output can, therefore, be calculated direct without conversion.

A miner's inch (m. i.) is taken as 1.5 cu. ft. of water per minute.

(a) 1 m. i. will develop 2 hp. with 1000-ft. head.
(b) 1 min. ft. will develop 1 kw. with 1000-ft. head.
(c) 1 sec. ft. will develop 8 hp. with 100-ft. head.
(d) 1 sec. ft. will develop 6 kw. with 100-ft. head.

(a) Q (miner's inch) $\times$ H (feet) $\times$ 0.002 = hp.
(b) Q (cu. ft. per min.) $\times$ H (feet) $\times$ 0.001 = kw.
(c) Q (cu. ft. per sec.) $\times$ H (feet) $\times$ 0.08 = hp.
(d) Q (cu. ft. per sec.) $\times$ H (feet) $\times$ 0.06 = kw.

The conversation of kilowatt to horse-power or *vice versa*, can readily be made in the usual manner. The value of these equations lies in the fact that losses such as friction or head loss in the pipe, generator, water-wheel, and transformer losses are all taken into consideration, that is, at the values usual in high-head installations of Western practice.

Assuming a pipe-line efficiency of 95%, a water-wheel efficiency of 80%, a generator efficiency of 96%, and a transformer efficiency of 98%, the plant efficiency is 71.5%. Allowing a still further loss of 1.5 to 2% for inefficiency in regulating nozzle losses, etc., the switch-board output will be 70%. Assuming well known constants, the following deduction from one of the formulae may be given:

w = 62.5 lb. weight of 1 cu. ft. water.
1 hp. = 33,000 ft. lb. per min.
1 m. i. = 1.5 cu. ft. of water per min.
Q = quantity of water.
H = static head from forebay to centre of nozzle for impulse wheels and from surface of head-water to tail-water surface in the case of turbines.

From the well known equation P = QwH may be calculated P or hp. $= \frac{1.5 \times 62.5 \times 1000 \text{ ft.}}{33{,}000} \times 0.70 = 1.990$, or practically two horse-power. The approximation being large by one-half of 1%, the other formulae are obtained directly or deduced from the foregoing.

A practical application of the formula is as follows: Assume the Chalf Bluff ditch is furnishing the Deer Creek power-house continuously with 3500 m. i. of water, the head is known to be 830 ft. Therefore $3500 \times 830 \times 0.002 = 5810$ hp. or = 4360 kilowatt.

Laterite is a rock containing free aluminium hydrate usually associated with hydrates of iron and manganese and oxide of titanium. Being a product of weathering, its formation requires a moist climate and abundant vegetation.

*From *Pacific Gas and Electric Magazine.*

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Decrease of Value in Ore-Shoots with Depth

The Editor:

Sir—My attention has recently been called by a prominent mine manager to the fact that in nearly all great gold mines there is a gradual decrease in the tenor of the ore as depth is attained, with a suggestion that this has been overlooked by economic geologists. I do not remember to have read a comprehensive discussion of it, and I desire information on the subject. It is, of course, a well known fact that a gold mine is first opened on the oxidized ore near the surface, which has commonly been enriched by mechanical concentration. Then in some veins the upper portion of the sulphide zone may have had its average tenor increased by the secondary enrichment process. But after the mine workings have penetrated beyond the influence of the surface, is there, as a general rule (of course recognizing many exceptions), a further gradual decrease in the gold content of the vein as depth is attained? I have generally attributed the decrease in tenor of the ore mined as the operation attains age to the reduction of working costs and increased capacity of plant, enabling and often requiring the mining of lower-grade ore, and also to the fact that as the commercial ore is usually in the form of shoots limited vertically as well as horizontally, it becomes increasingly more difficult to find new shoots at depth. In large veins a shoot of ore may extend down 1500 ft. or more and then pinch out. A new shoot may begin at about that level somewhere else on the vein, and it may or may not be found by the exploratory work carried on. In the meantime the mill crushes a lower and lower grade of ore from reserves until some time after the mine has ceased to be profitable. These facts, which I believe no one will dispute, tend to obscure the problem. In not a few veins even where the ore-shoots are vertically elongated, there is a sort of horizontal banding, certain levels being much richer than the levels above and below. It is also quite common for the tenor of ore to greatly change upon a vein passing from one formation to another. I have in mind at this moment the fact that at many old mines in the Great Basin region veins have become of much lower grade upon passing from the Tertiary volcanic rocks to underlying granite. This may be anticipated by a geological study of the locality. The question is whether in the majority of large gold-quartz veins, if 5000-ft. depth of the vein below the enriched portion near the surface be divided into 1000-ft. vertical sections, it will be found to be a rule that there is a progressive decrease in tenor of all the ore in each successive deeper section; in other words, as most gold-quartz veins have been filled from below, is it a rule that their primary ores decrease in tenor toward the source of the gold? This has a practical bearing, for if it be true it is necessary in judging a partly developed mine to take it into account (in addition to the decrease in tenor of ore mined we naturally expect for the reasons given above). If there be such decrease, it may be possible to determine approximately the average rate and apply this in investigating prospects, the only question remaining being as to whether any given prospect is one of the exceptions; the safe way would be to assume that it is not, except where the known geology presented evidence that it is. I believe this is a subject worthy of extended study.

OSCAR H. HERSHEY.

Kellogg, Idaho, June 30.

[The problem Mr. Hershey suggests is most important. We think he is right in his surmise that the apparently lower grade of ore mined with increasing depth is to be referred to secondary agencies having enriched the surface ore, or within the limits of usual mining, decreasing costs having permitted the handling of leaner material. We doubt whether, in the case of a primary orebody, there is sustained evidence of a general change in richness in any direction. However, the matter is open to question and authentic data are much needed. Who will present some tangible evidence? Only from a multiplicity of observations can any rule be deduced.—EDITOR.]

Crushing by Stages

The Editor:

Sir—The suggestion made editorially in the current issue of *The Mining Magazine*, based on the views held by Edward J. Way, that a combination of heavy and light stamps should prove to be advisable, seems to me a valuable one, and it would not surprise me to see, before long, not only a combination of two, but possible also of three, and, in exceptional cases, more sizes in operation, to be followed by tube-mill grinding. The modern practice of comminution has been a source of astonishment to me for many years, believing, as he does, that the weight of the tool should be proportioned to the size of the material. To grind rock down to 40-mesh with a 100-lb. stamp, or a 1000-lb. muller, seems as unscientific as it would be to cut a watch wheel in a 48-in. lathe. There is no getting around the fact that for correct grinding it is necessary to select the weight of the hammer, or rather its energy, so that it is just sufficient to crush the particles to be ground, and, as a corrolary, that all particles smaller than those suitable for each machine be removed before admission to it. This principle is interestingly illustrated in the construction of the Hardinge conical tube-mill (to use this, apparently unavoidable, misnomer), the ingenuity and efficacy of which the mining fraternity is so slow in recognizing. To what extent these principles can be carried economically into execution can only be determined in each case individually, but it is safe to say that they are capable of application to advantage in almost every existing plant, and the nearer approach to perfection in design and workmanship of machinery, and the greater in experience gained in connecting and operating the independent units, the more

of the latter will it be profitable to use, thereby coming closer to the theoretical efficiency. One of the reasons why the stamp-mill, in spite of its faults, has so long maintained its supremacy in competition with other milling devices, is because of its superiority in discharging the ground material. If, then, stamps were chosen so that their weight did not exceed that required to accomplish the breaking of the ore, they would make as economical a crushing machine as can be expected for the smallest sizes, where stamps would become impracticable, and tube-mills, preferably of the conical shape, would take their place.

Fundamentally the stamp which automatically stores a certain energy and re-delivers the same at each blow, regardless of the power required, may not be an ideal machine, but its simplicity of construction and operation will probably assure it the foremost place among medium-sized crushing devices, provided it is adapted to the work to be performed on the lines that have been suggested.

F. Cremer.

Los Angeles, July 6.

Wet Gold-Assay

The Editor:

Sir—I have read with considerable interest Mr. Howson's letter (which appeared in your issue of June 25), on Mr. De Luce's wet method of gold assay. In his experiments 7a, b, c, and d, in which a telluride ore is treated with aqua regia and then evaporated to dryness, I should be a little afraid, in so rich an ore as the one he used, that there might be a danger of loss of gold by volatilization of its chloride. It would have been interesting to know if Mr. Howson assayed the final residue and whether he found the whole of the missing 10.6% there.

While on the subject, the following method of assay may be of interest. Though not an assay in the proper sense of the word, it has merit, and, as I have never seen an account of it in any text book, I give it to your readers for what it is worth. It was shown to me by a prospector named Cohen, and, as when he found anything worth while he was in the habit of bringing it to me for accurate assay, I know that he made some fairly close guesses by the process. He was working on low-grade ores, and he took for each test a pound of ore that had been crushed to pass a 100-mesh screen. He first roasted the ore, then added one ounce of doubly-distilled mercury, sufficient water to make a thick mud, shook well in a bottle, and then by careful panning recovered the mercury. Having obtained the mercury, Cohen placed it on a hard-glass watch-crystal and evaporated it gently over a spirit lamp, finally, when all the mercury was evaporated, bringing the glass to a red heat. The gold was left in a thin film on the glass, to which it adhered tenaciously. For the purpose of comparison, he took ores of known assay value and treated them in the same way. The watch glasses—of which he had some dozens—with the gold on them, he carried around with him to compare with tests he made of ores of unknown value. Not only quantity, but fineness—from color—had to be judged.

Of course I am not putting this forward as an accurate test, but for the prospector, as I have said before, it has merit. The only kit necessary is a spirit lamp and support; watch-glasses, which may readily be cleaned after the test with a few drops of HCl and a crystal of $KClO_3$ or $K_2Mn_2O_8$; mercury: an iron pan for roasting, which operation may be done over an open charcoal fire; and the comparison watch-glasses.

F. H. Mason.

San Diego, California, June 29.

Thawing Giant Powder

The Editor:

Sir—I have used a common chicken incubator for the past two years for thawing giant powder, with most gratifying results. It has the following advantages: (1) there is a dry even heat, just what is wanted for powder; (2) no danger of overheating; (3) the powder is always ready; (4) the time saved is worth many times the cost of the machine; (5) always having the powder in prime condition for firing, you will get the very best results; (6) the cost of fuel is low; (7) last, but not least, it is perfectly safe.

Now, Mr. Miner, or powder user, don't laugh at this method, but just try it, and be convinced that an incubator can't be beaten for a safe and economical method of thawing explosives. Don't rush off and buy a new one, but enquire of your neighbors. Most likely you will soon find one that will answer your purpose just as well as a new one, that can be secured at a very moderate price. I have never had to change the regulator on my machine, and my powder is always in the very best condition for use. I feel sure that if incubators were used for the thawing of explosives the number of accidents would be greatly lessened.

A. L. Lamb.

Ashland, Oregon, July 6.

The Cheapest Mining.—The cheapest mining and milling of gold ore in California, that has been recorded, was done at the Spanish mine, near Washington in Nevada county. The ore was mined in an open-cut, trammed through a tunnel to the mill, which consisted of a Blake rock-breaker and three Huntingtons. There were employed 3 white men, one of them as foreman; and 8 Chinese. This crew broke all the ore and sent it to the mill, handling 4000 tons per month, and milled it at a cost of 58½ to 60½c. per ton, the ore assaying about $1. This statement includes only the actual cost of breaking the ore, tramming and milling it, no account being taken of the cost of the tunnel 1200 ft. long which had been run previously, at a probable cost of $6000, nor did it take into consideration the cost of a raise 350 ft. high, which no doubt cost $1500 more. Had the total cost of this 'cheap mining and milling' been charged with the cost of the work previously done by others, the operation would have been at a loss, but as it happened, one set of men paid for the preliminary work, another set for the mining and milling—the latter at a profit. This instance illustrates how comparisons of costs to be valuable must take into account all the circumstances.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Coal dust ground to pass 200 mesh will explode on contact with flame or an electric spark.

Nitroglycerin is prepared by slowly running glycerin into a mixture of the strongest nitric and sulphuric acids, the whole being stirred and kept cool during the process of mixing.

Exports of manganese ore from Russia during the year 1909 amounted to 611,000 tons, as compared with 440,000 in 1908, and 608,000 in 1907, showing an advance last year of 171,000 tons over the previous year, and of 3000 over 1907.

Rope drives have replaced both belts and gears in a number of large plants, both efficiency and economy being claimed by the advocates of the drive. Flexibility and lack of broken gears due to sudden changes of load are probably the main reasons for the use of rope in power transmission.

Time spent in loading and unloading forms a considerable portion of the expense of shipping when a large amount of ore is to be handled, and a number of manufacturing companies are now building all-steel cars with both side and centre dumps to facilitate rapid handling of the material.

Black blasting powder comes into the market in the form of grains whose edges have been rounded off by rubbing together in a revolving barrel and which are usually coated on the surface, or glazed, as it is termed with graphite, or black lead. The object in rounding and glazing the grains is to render them free running, and the glazing also serves to delay somewhat the taking up of moisture from the air by the grains.

Where the floor of a mine tunnel is very wet and is the cause of much annoyance or expense, drainage may be accomplished by laying common drain tile in a trench cut on either side of the track. The tile need have no flanges and should be laid about an inch apart in order that the water may seep in, which it could not do if the tile sections were closely joined. Where this expedient has been tried it has been found to work satisfactorily.

Explosives should not be exposed for any length of time to direct sunlight, because this may lead to decomposition in those containing nitroglycerin, nitrocellulose, nitrostarch, or substances of that kind. Explosives should be stored in a dry place, for many of them contain considerable quantities of ammonium nitrate or sodium nitrate and will take up moisture from damp air. This not only makes them harder to fire, but causes a weaker explosion.

Lubricants are tested in six ways: (1) by chemical analysis; (2) for specific gravity; (3) for relative viscosity when new; (4) for gumming action; (5) for flashing and burning points; (6) generally, by the testing machine. The last is the most efficient and in its essential features consists of a pendulum hanging on the test journal, whose brasses can be adjusted for any pressure by a screw. The journal being rotated to the right, the pendulum moves to the left and a scale at once indicates the friction per square inch of journal.

Steel mine-timbers were placed in the Foxdale mine, Isle of Man, in 1890, and gave great satisfaction. Adjacent sets of Irish larch and Norway pine, put in at the same time, failed utterly in less than two years, while the steel under the same conditions was as good as new. They cost twice as much as the timber, but as they would last at least twice as long, they were undoubtedly superior on the score of economy, to say nothing of their other advantages. In the mining districts of Michigan and Minnesota there are a number of mine shafts timbered with steel and lagged with plank. These shaft-sets are made similar to timber-sets and are lowered into position as the excavation proceeds. Every 50 ft. or more steel beam bearers are placed transversely, after which the hangers are removed.

Zinc dust used in cyanidation in this country comes mainly from Germany, though some is now being made at Pueblo, Colorado. The material is the 'blue powder' of the zinc smelters, and consists of finely divided metallic zinc in part covered by a film of zinc oxide. The individual particles are often in a state of tension as in 'Prince Rupert drops,' and hence the material is explosive under some conditions. Blue powder is a troublesome by-product in zinc smelting, and since zinc dust is bought in carload lots by the companies that have adopted the Merrill process, there would seem to be an opening here for a good American business. The ideal zinc dust would consist of 97% metallic zinc and 3 of metallic lead. The freer it is from oxide the better, and it is particularly important that it should be even in composition. Dust from new sources should not be used without thorough preliminary tests.

Tonnage crushed in mills is often estimated merely by count of cars dumped per week or month. This gives at best only a rough approximation to the truth. If a fair proportion of the cars are weighed daily, if moisture samples are taken when the material is not quite uniform in this respect, and if a correction is made periodically for the differences in the volume of the ore in the storage bins, the results are reliable within about 2%. A slightly higher degree of accuracy is claimed for the continuous-weighing devices, which are operated by the pressure on a belt-conveyor, and the accuracy of which can be checked by occasionally comparing the record obtained with a carload of ore weighed by reliable scales. When using these devices the corrections for moisture and fluctuations in mill-storage must not be neglected. When 'mill-time' is used in reckoning tonnage, the time lost while repairing must be carefully recorded, and the results are reliable only when based on past experience of the average duty performed with a particular ore.

Special Correspondence

NOME, ALASKA

Winter Work and Spring Clean-up.—Costs and Labor. — Season Opens Late.—Pioneer Mining Co. Absorbs Miocene Ditch Co. —Seward Peninsula R. R. not Operating.—Stuart-Weatherly makes Heavy Investment for British. — Dredging Plans. — Iditarod News Good.

Although prospecting has been actively carried on in many localities, no new finds of any importance have been made during the past winter. The attractive, but always disappointing belt of tundra lying west of Nome between Snake river and Cape Rodney, was the scene of two or three stampedes during the winter based upon the finding of ancient beach deposits which were the supposed westerly extension of the third beach. Further development, however, proved in each case that while the indications were favorable, the elusive pay-streak was not there. About 300 miners have been steadily employed during the winter by the operators in the immediate vicinity of Nome, and about 250 have been engaged in prospecting by shafts and drifts and in extracting small dumps on their own account. The Pioneer Mining Co., Scandia Mining Co., and the Bessie mine were the leading employers of labor, having on their payrolls more than half the total number employed in this vicinity. The Wild Goose Mining & Trading Co., which has been such a large employer of labor in the years gone by, did not attempt any operations during the winter. The season is opening late. The weather has been steadily cool during May, and thus far, up to the tenth, in June. The hills about Nome are still covered with snow and the water for spring sluicing started two weeks later than usual. The result is that sluicing of winter dumps is just now in full swing, whereas most years this work has been finished by the end of the first week in June. I estimate this spring's clean-up in the immediate vicinity of Nome at about $1,000,000. This is the smallest for several years. Driving operations during the past winter have been carried on in much lower-grade ground than formerly, and while some large dumps have been extracted they do not contain the quantity of yellow metal that similar dumps formerly contained.

The labor union, carefully sizing up the situation early last winter, with rare good sense fixed the winter wage scale at one dollar per day less than had prevailed during the three previous winters, and thus without any friction or dissatisfaction operators were able to secure good labor at $3 per day and board. This condition undoubtedly encouraged some of the operators to attempt the extraction of gravel that has been heretofore considered too low grade to handle. The average cost of working a 2 to 3-ft. pay-streak in frozen ground in the Nome district, placing the pay-gravel in a dump on the surface, and ground sluicing and shoveling it into sluice-boxes in the spring, has been about $4 per yard, and operators have hesitated to attempt to mine ground that sampled less than four or five cents per pan, which is equal to $6 to $7.50 per cubic yard. During the past winter, however, much of the material hoisted averaged only three cents per pan or $4.50 per yard. Louis Stevenson, superintendent for the Pioneer Mining Co., informs me that he has several thousand cubic yards of gravel in dumps this spring mined from a pay-streak seven or more feet thick which averages only $1.875 per yard and yet leaves a profit of $0.625 per yard, allowing for the usual cost of sluicing. This case, however, is exceptional, as pay-streaks of this character are usually only three feet or less in thickness, which necessitates handling about two feet of waste, and as the work was done near an established camp it does not take into consideration the cost of equipment, nor make any allowance for depreciation. Making all due allowances, however, it is still the most creditable showing yet made in this district and brings into the class of profitable ground much territory that has been heretofore considered too low grade to handle.

Though I am not rellably informed as to operations in the Kougarok and Candle Creek districts during the winter, general reports have it that Candle will sluice about $200,000 and Kougarok and Inmachuk about $75,000 from their winter dumps. Gold Run and other outlying districts will probably yield $50,000, making a grand total of $1,325,000 for Seward Peninsula from winter work.

Among the changes in the larger affairs of the Peninsula which have taken place during the winter, one of the most important is the absorption of the Miocene Ditch Co. by the Pioneer Mining Co. The latter company has owned a minority interest in this enterprise for several years, but it has lately acquired control, and henceforth this ditch system, which embraces more than sixty miles of ditches and is capable of delivering between 2500 and 3000 miner's inches of water to the vicinity of Anvil creek, will be entirely in the hands of the Pioneer Mining Co. The price paid and other particulars of the deal have not yet been announced here. The rudest shock which the district has received for a long time was delivered by T. A. Davies, local manager for the John J. Sesnon Co. and the Northwestern Development Co., upon his arrival here on the *Corwin* June 2. The Northwestern Development Co. controls the Seward Peninsula railway, which runs from Nome to Lane's Landing on the Kougarok river and is the only means by which either freight or passengers can reach the Kougarok district early in the season before the ice is out of Port Clarence bay or late in the fall after ice begins to form in the river. Mr. Burroughs, local superintendent for the railroad, started the trains as usual this spring as soon as the track was clear of snow, but Mr. Davies promptly ordered all engines into the sheds the day of his arrival and the road ceased to operate. Whether this stoppage is temporary or is indefinite is not known. The reason assigned by Mr. Davies is that Col. Lionel Stuart-Weatherly, British vice-consul at Nome, and who for some years has been a familiar figure here operating mines on Buster creek and elsewhere, and who is said to have heavy British backing, has secured control of the Northwestern Development Co., and until his arrival here on one of the later boats the railroad and all other Northwestern Development Co.'s holdings will remain in *statu quo*. It is said the railroad has long been losing money, and it is feared by those who have interests in the interior that the tie-up may be indefinite. Col. Stuart-Weatherly is also said to have become the controling factor in the John J. Sesnon Co. This company has a monopoly of the lighterage business of Nome and is the chief purveyor of fuel, both coal and crude oil to Seward Peninsula. It has a monopoly of the crude oil business. Col. Stuart-Weatherly has also taken over the Nome Mining Co. assets, including its electric power plant on Bourbon creek, near Nome, having a 500-kw. generator driven by a steam-turbine engine, and having boiler and building capacity for an additional unit of the same size. With the plant has gone the much discussed Bourbon Creek dredge, which was completed in 1908 and sank after running only a few days. The bucket line caught in the side of one of the pontoons and tore it out, the boat sinking in a few minutes. The hull rested on an uneven bottom and was warped out of shape, so that most of the season of 1909 was spent in re-building and strengthening the various parts of the dredge. It made a short run last season and was said to have made a creditable showing. Seward Peninsula, and especially the Nome district, evidently looks good to the Colonel and his backers, and it is to be hoped that his various enterprises will prove remunerative. His first move was made early in the winter when he acquired by purchase the Nome Electric lighting plant which was owned by the John J. Sesnon Co. Shortly after his arrival in Seattle on one of the last boats from here last fall, word was wired in here to turn over the lighting plant and all stores and equipment to Arthur Gibson, with whom he had arranged to be his superintendent of the plant. This purchase has been followed by the others enumerated, according to our best information here, and it is believed to be the intention of Col. Stuart-Weatherly to greatly enlarge the power-plant and to build and operate dredges in this vicinity and sell power to others.

A. J. Stone, promotor of the Taylor Creek Ditch Co. in the Kougarok district, and who for several years has been its general manager, has been succeeded by Charles A. Ferrin, formerly president and general manager for the Northern Mining & Trading Co., which had valuable mining claims on Anvil creek in its palmy days. Mr. Stone will devote his energies to the construction of his great hydro-electric plant at the northern base of the Saw Tooth mountains, the details of which were published in the *Mining and Scientific Press* in the issue of November 20, 1909.

The dredging possibilities of Seward Peninsula are evidently to receive a thorough test in the near future. Our advices are that at least ten new dredges are being shipped to Nome and outlying districts on the first fleet of boats with a probability of two or three more to follow later. Of those assured, one is to be constructed on upper Ophir creek by the Wild Goose Mining & Trading Co. One on Solomon river near the mouth of East Fork, for which Frank I. Reed of Nome is general manager, and one on Solomon river near the mouth of Big Hurrah creek, which is being built by Claes. Flodine and associates of Chicago. Jere Wilson, who last year installed two dredges in the Council district, is now to install one on the Casadepaga creek. A. J. Soupje is shipping one for Melsing creek near Council City. C. Sievertson is shipping one for Spruce creek near Solomon. John A. Webb is shipping one for Shovel creek, a tributary of Solomon river. The Pileu Dredging Co., in which Joseph F. Pileu of Nome is a large stockholder, and for which he is general manager, is shipping one for Otter creek near Nome. Roland Sutherland, Colin Murray, and Pete Hogan are shipping one to be installed on Moss gulch, a tributary of Nome river, and R. L. Braucht, treasurer of the Gold Beach Dredging Co., which last year installed a dredge on Dry creek near Nome, is shipping one to be operated on the Casadepaga creek. These dredges are all modern substantially constructed machines and of a capacity suited to the character of the ground in which they are to operate. As stated in a former letter there is no doubt among those familiar with Seward Peninsula that there is a splendid field here for dredges of moderate capacity. The most suitable dredging areas are comparatively shallow, ranging between 10 and 30 ft. deep, and dredges having 3 to 5-ft. buckets are likely to be most successful. A danger to be feared by those having the welfare of the dredging industry at heart, is that too much haste will be shown by those in a position to raise money for dredge construction and boats will be installed upon ground which is unsuited for dredging. No one should invest any money in a dredging scheme in any country until the area proposed to be dredged has been carefully drilled or otherwise tested, and in this country it should not only be tested for gold, but also for permanent frost which may make an otherwise rich dredging area worthless. The larger stream beds are almost invariably thawed ground, but many small streams rich in gold are so spotted through with frozen patches as to spoil them for dredging purposes.

From the fact that so many promoters have been successful in raising money for dredge schemes during the past winter it is evident that such enterprises are looked upon with much favor by the investing public. In order that the industry may be developed along legitimate lines and attain the success warranted by the natural conditions which prevail in this field, it is to be hoped that the public will discriminate between the flamboyant, automobiling, stock peddler, and the legitimate promoter, who represents a meritorious proposition that has been carefully tested and proved. Investors should insist upon having an engineer's report covering all the essential facts necessary to the success of the scheme before placing one dollar within the control of the promotor of a dredge scheme.

Unloading Freight on the Ice at Nome.

Favorable reports come from the Iditarod country. Paydirt has been found on several creeks, including Otter, Flat, Black, Glenn Willow, and Chicken. Flat creek, a tributary of Otter creek, is said to contain a pay-streak 400 to 500 ft. wide, and good prospects have been found along its full length, which is about four miles. A correspondent writing from there recently says: "There is great uniformity of pay. No big pans, none better than 25c., but many holes have shown good prospects, such as nine feet of 6c. dirt and ten feet of 8c. dirt." Of the gold-bearing material he says: "It is a sort of glacial mud, not unlike gumbo, and is most difficult to pan. The rocks are rough fragmental pieces showing but little water wear and these are embedded in the gumbo. The creek is very flat and is not frozen. It will be difficult to get drainage. The average depth is about 17 feet."

TORONTO, CANADA

Porcupine.—High-Graders Convicted.—Cobalt Shipments.

R. W. Brock, Director of the Canadian Geological Survey, has returned from an inspection of the Porcupine Lake area, and his report is on the whole decidedly favorable, though he anticipates a wild boom and many losses through the exploitation of worthless claims. Of the 9000 claims that have been located in this district the majority have no present or prospective value, and many change hands on a purely speculative basis; but there are some really good-looking prospects. Quartz is remarkably widespread, and visible gold in abundance has been found at numerous and widely separated points. The camp is fortunate, he says, in having a number of strong interests take hold in its initial stages, to insure thorough development and testing of the more promising prospects. The prevailing rocks of the district are greenstones (including old diabase), quartz-porphyries, and schists, presumably of Keewatin age, with some slates, greywackes, and conglomerates probably of Huronian age. The quartz seems to occur in any of the rocks, and in all manner of forms. It is sometimes found in well defined veins, and also in large apparently isolated masses, the so-called 'domes', and again it occurs as irregular stringers which may swell out in places to large masses. The quartz holds many inclusions of country rock more or less altered in and along which pyrite is extensively distributed. The gold, which is often coarse, is distributed similarly to the pyrite with which it is usually rather closely associated, but some may be found in the pure quartz. A little galena, blende, and chalcopyrite may also be present. Next to quartz a ferruginous carbonate, probably ankerite or siderite, is the most abundant gangue mineral and it weathers deeply to reddish yellow iron oxide. The properties attracting most attention are the Timmons, Dome, and Foster. The Timmins has a substantial camp, buildings, and good equipment with three shafts down on the largest vein which has a maximum width of 20 ft. The deepest shaft is down 90 ft. at which depth the vein is 12 ft. in width yielding good ore carrying free gold. There are some 300 tons of ore on the dump, several lots of which sent for sampling are said to have yielded high results. The ore now being taken from the bottom is equal to that on the surface. Several other veins have been stripped, one of which has been traced 300 ft. and shows gold at several points. At the Dome two large masses of quartz 60 ft. or so in width and of considerable length have been opened. The surface of the quartz shows coarse gold and sampling is reported to give satisfactory results. Several shafts have been sunk and diamond-drilling is being undertaken to determine conditions at depth. A small test-mill is being erected. The Foster vein is a belt of iron carbonate filled with transverse masses and veins of quartz, containing many inclusions of the carbonate, in which sulphides and gold have been deposited. The vein where exposed has a width of from 6 to 20 ft. and has been traced for nearly half a mile. Fine showings of gold occur. The development of the camp during the next few months, which will furnish some indication of conditions at depth, will be watched with much interest. The district is now comparatively easy of access, the route generally taken being from Kelso at Mile Post 222 on the Temiskaming & Northern Ontario railway by stage for 12 miles to the inlet of Frederickhouse lake, and the rest of the way by gasoline launches. A service is also being established from the Canadian Pacific railway at Bisco down the Matagami river to a point near the Timmins mine.

The mining men of Porcupine and Gowganda have been for some time urging on the Temiskaming & Northern Ontario Railway Commission the need of an extension of the system into those districts. The Commission after giving the matter full consideration has decided in the negative, and Mr. Englehart, the chairman, a few days since announced that the extensions would not be undertaken at present or in the near future, as both camps had yet to prove their worth, their present stage of development not being such as to warrant extension as a business proposition. The number of high-graders, prosecutions against whom have been hanging fire for some months owing to legal technicalities, were finally disposed of on June 22. The charges of theft were dropped and convictions of illegally buying or selling ore were recorded. J. E. Wilkinson, president of the J. E. Wilkinson Co., the principal offender was fined $300 or six months in jail, three others received sentences of $200 or six months, and two more were let off more easily. These proceedings took place under the old law under which it is difficult to obtain a conviction and most of the prisoners pleaded guilty of the lesser offence. The present provisions are much more stringent and future offenders will hardly escape so lightly. A still more flagrant case has just come to light resulting in the arrest of George E. G. Rogers, accountant of the Lucky Godfrey, of Elk Lake, and an ore-sorter in the employ of the company. Last April a shipment of 18 tons of high-grade ore was made to the smelter. It was valued at $40,000. When the bags were opened they were found to be largely filled with country rock and low-grade vein matter to the value of about $5000.

Cobalt ore shipments are increasing, the consignments for the two weeks ended June 24, amounting to 1750 tons. A good find is reported at the Peterson Lake where a 5-in. lead of smaltite carrying native silver was struck in a cross-cut at 200 ft. The O'Brien has opened high-grade ore in a winze sunk from a drift in No. 16 shaft. The Bailey is down 160 ft. at which depth a station is being cut. The Victoria vein of the Crown Reserve, intersected in May to the south of the main vein, is holding out in width and value. It contains high-grade ore, one assay showing 6000 oz. Another important ore-shoot has been found on the Lawson property of the La Rose in a drift at the 50-ft. level on No. 1 vein. A new vein of high grade has been discovered at the Temiskaming on the 400-ft. level.

The University of Toronto has added a professor of mining to its staff and appointed H. E. T. Haultain to the position. Mr. Haultain's work as a mining engineer and lecturer on mining has amply proved his fitness for the post.

LONDON

Radium Exploitation.—Rezende Gold Mine.—Brakpan Plant.

Some time ago I recorded in these columns that the National Minerals Corporation was exploiting radio-active pitchblende found in the St. Ives mines, Cornwall, and had formed a company with a large capitalization called the British Radium Corporation for the purpose of conducting extraction under the general direction of Sir William Ramsay. We have had another company of similar indefinite promise before the public this week. The name is the National Radium Trust, and the capital is £150,000. The list of directors is headed by Earl Russell. The objects of the company are two-fold: first, to sell or lend radium to medical men and scientists generally, and second, to acquire and develop uranium mines in Portugal. As regards the first object, the price to be charged for the sale is £16 per milligram of pure radium bromide; and for the loan of it the charge will be £4 for 10 mg. for the first 24 hours and 16s. for every succeeding 24 hours. The mines to be acquired are in the State of Veira-Baixa, Portugal, and the mineral containing the radium is variously given in the prospectus as uranite and autunite. Presumably both occur. The green uranite is the phosphate of copper and uranium, and the yellow autunite is the phosphate of lime and uranium. The crude ore is to be sold to a firm in Paris dealing in uranium and radium. Later it may be concentrated and treated at the mine. The actual value of the ore as far as radium content is concerned is not clearly put, though it is stated that the company expects to receive £32 per ton of concentrate containing 3% of U_3O_8. The minerals seem to be disseminated in minute quantities throughout cracks in granite and the uranium content is only a small fraction of one per cent.

The Rezende gold mine in Rhodesia is one that has given English shareholders much anxiety and has for years been a sink for capital. During the last year or two the energies of the Farrars have put a better complexion on affairs. The mine is situated in the Penhalonga valley, in the Umtali

district. It was first worked in 1892 when the United Goldfields of Manica undertook its development, and the company has been reconstructed several times under different names. More recently control has been acquired by the Farrar-Anglo-French group and the company was reconstructed in December 1908 under the name Rezende Mines, Ltd. The capital then issued was 48,990 shares of £1 each, 26,600 being allotted to the shareholders in the old company, 16,645 to pay for additional property, and 5738 for cash to subscribers to the debentures, of which £47,500 was subscribed for the purposes of working capital. These debentures carry 8% interest and are redeemable by ten annual drawings commencing in 1912. The report now issued covers the period from the reconstruction in December 1908 to December 31, 1909. During this period, the attention of C. R. Pinder, the manager, has been largely devoted to development in the mine and to overhauling the plant, and the mill did not resume operations until the middle of October. A new hoist, an air-compressor, and three centrifugal pumps, all operated electrically, have been installed, and the company has also provided funds for the extension of the Penhalonga company's electric generating plant from which current is bought in addition to the company's own plant. A sorting belt and an aerial ropeway have been erected. The ore reserve on December 31 was estimated at 52,270 tons averaging 7.7 dwt.; in addition 72,742 tons in the old workings averaged 4 dwt. and 43,430 tons is partly developed. During the 67 working days in October, November, and December the 30-stamp mill crushed 9000 tons averaging 8⅛ dwt., and produced 1823 oz., an extraction of 4.05 dwt. Treatment on Wilfleys yielded 106 tons assaying 108 dwt. gold and 89 dwt. silver per ton, which were treated by cyanide. The yield from concentrates was 575 oz. In addition 4838 tons of sand assaying 2.28 dwt. and 1286 tons of slime assaying 2.2 dwt. were cyanided and yielded 436 oz. The total recovery was 2834 oz. or 6.3 dwt. per ton. The percentage of recovery was low, but the plant has not been running long and the directors hope for an improvement later on. The revenue was £12,099 or 26s. 10d. per ton milled, and the cost of mining and treatment was £10,074 or 22s. 6d. per ton, which includes £1800 toward redemption of the development account. During the year £11,872 was spent on development work and £6050 on sinking a new incline shaft. Operations are rendered difficult by sudden and unexpected inflows of water. Since the close of the year development has disclosed other bodies of ore and the outlook is continually improving. It has been decided that it is best for the company to confine itself to the quartz veins and not to undertake the exploitation of the reserve of schistose ore in the old workings. These have therefore been let to tributors.

The Brakpan mine is one of the most interesting of the deep levels in the Far East Rand. It belongs to the Consolidated Mines Selection group and the gold deposit possesses the unusual characteristic of being situated below coal mines. W. L. Honnold is consulting engineer and C. B. Brodigan manager. The deposit has been developed by means of two vertical shafts, one below the other on the dip, nearly a mile apart, and connected by means of an incline. The depths of the two shafts are 3100 ft. and 3700 ft. The reserve on March 31 was 905,726 tons assaying 6.3 dwt., over stoping widths varying from 40 in. to 77 in. and averaging 52 in. Blocks totaling 428,824 tons averaging 2 dwt. have also been developed and are included in the reserve. A decision as to the metallurgical plant was postponed in order to enable the engineers to take advantage of trials of recent improvements, and the final plans were only adopted in March. The work of excavation has been started, and the orders for the machinery have been given. The battery will consist of 160 stamps weighing 2000 lb. and the buildings and bins will be made large enough for an extension of the stamps to 200. The exact coarseness of crushing has not yet been decided. The initial cyanide plant will have a capacity of 60,000 tons per month. Other features of the plant will be classifying cones, air-agitation, vacuum-filters, and zinc-dust precipitation. A year ago development was hindered by the sudden inflow of water at several levels simultaneously. A special pumping plant has been provided at No. 2, the deeper shaft, and the water will be raised in three lifts. The capacity is 1,000,000 gal. per day, and the pump chambers have been made sufficiently roomy to admit of the plant being made half as large again. The balance sheet dated December 31 shows that £115,133 has been spent on No. 1 shaft and its equipment, and £166,739 on No. 2 shaft; the connecting incline has so far cost £54,568. Development has cost £52,889, and £52,560 has been spent on buildings and surface plant. On December 31, the company had £372,333 cash in hand.

SALT LAKE, UTAH

Utah Copper Co.—Ohio Consolidated.—Yosemite Mine Drained.—Beck Tunnel.—Stock Market Depressed.

The Utah Copper Co. now claims the distinction of being the largest producing mine of copper in the world. While there are other companies composed of various subsidiaries, notably the Amalgamated, which produce more than this company, Utah Copper is producing from one mine and has outstripped Anaconda and the famous Calumet & Hecla. The production for May was well above 8,500,000 lb., and for June bids well to pass the 9,000,000 mark. The work of enlarging the mill capacity will be carried on until the three plants are treating 20,000 tons of ore per day, about 8000 tons more than is mined daily at all of the Butte mines. During the past week the Utah Consolidated began shipping its ore over the new tramway to the Tooele smelter. The company still has a few days' run on its old tonnage contract with the Garfield smelter and will deliver the ore by shipping to Tooele and thence over the new Tooele Valley railroad and the San Pedro instead of by the Denver & Rio Grande, as formerly. As soon as this contract is completed the International will commence receiving the ore. The first reverberatory furnace is now completed and unless something goes wrong the company should be treating ore by the first of August.

F. Augustus Heinze and Colin MacIntosh, manager for the Ohio Copper Co., have gone to Europe in their endeavor to finance the company. It was their intention to visit several of the great financial centres, but it is reported that their mission has so far been successful in London, and that it may not be necessary to proceed farther. The company should have about $1,000,000 to complete its mill and put it in first-class shape.

A drift from the Mascotte tunnel has penetrated the porphyry dike which has held the water in the Yosemite mine, and for the first time in eighteen years the lowest levels in the mine are accessible and the property is in shape to allow of deep development. The Yosemite was worked to the 800-ft. level as a lead mine, but no attention was paid to large low-grade deposits of copper, as the smelters at that time did not accept ore running less than 8%. Two of the old Tintic mines are in hard luck. Much surprise was occasioned when the announcement was made that the directors of the Mammoth had levied an assessment of 10c. per share. The Mammoth is one of the old mines of the district and has paid dividends of about $2,000,000. Some of its ore was sensationally rich and one car marketed a few months ago netted the company $100,000. The ore is pockety and apparently played out. Then the suit which the Mammoth has been fighting with the Grand Central for nearly ten years was decided in the United States Supreme Court and the Mammoth was forced to pay $175,000 damages. A few days ago an accident wrecked the cage and the hoisting engine, and these things occurring one after the other has brought the company to the point of calling on the stockholders for help. The annual report of the Beck Tunnel Co. has been issued, showing that the company operated during the last fiscal year at a loss of nearly $22,000. The Tintic deposits are irregular in their occurrence, and in the case of the Beck have been pinching out, so that the company has been much disappointed in the quantities of pay-ore found. An assessment was levied last May, but the management announces that unless the present search for ore on the 100-ft. level is successful the

property must close down. Work of re-timbering the old Victoria shaft has been begun and when it is completed the shaft will be continued downward from the 550 to the 1000-ft. level. When it is in working order the mine will be operated from Eureka, whereas it is now worked through the Grand Central on the Mammoth side of the mountain.

The Kearsarge, one of the early mines of the State, has commenced shipping after an idleness of years. This is one of the mines of Dry canyon, adjacent to Stockton and one of the richest districts of this part of the country at one time. The nearby camp of Ophir is another that has been much neglected, but one of its old mines, the Buffalo Consolidated, is now shipping. After many annoying delays the Gold Springs Mining & Power Co. has succeeded in getting its producer-gas electric plant at Modena in operation. This will supply power for the mines at Gold Springs and Fay, Nevada, and should go a long way toward solving the difficulties with which these districts have been obliged to contend.

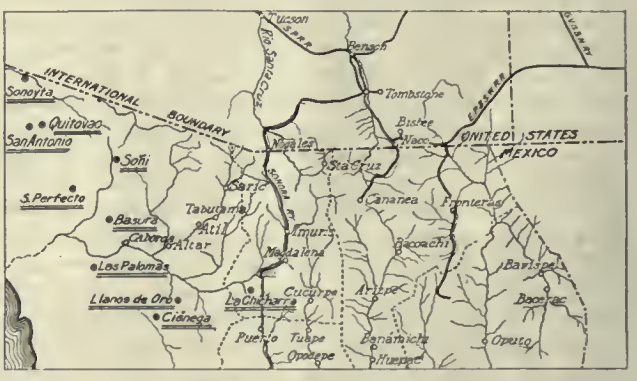
As an indication of the way the stock market has been affected by the present conditions, the report of the Salt Lake Stock Exchange is of interest. During the first six months of 1910 the total number of shares sold was 9,526,785, at a value of $2,856,191.75, against, for the corresponding period of last year, 21,205,035 shares of a market value of $11,681,354.97.

MEXICO

Moctezuma Copper Co.—Greene-Cananea Report. — Mines Co. of America Consolidation.

The Moctezuma Copper Co., the Phelps-Dodge organization that owns the great Pilares copper mine in the Nacozari district of Sonora, is at present operating only one of the two units of its 2000-ton concentrator at Nacozari, due to a scarcity of water, though the mine production is being kept up and and some high-grade ore is being shipped direct to the Copper Queen smelter at Douglas. At the concentrator, which was finished at the end of 1908 and is unquestionably one of the finest in the world, experiments with Deister tables are now being conducted with a view to their possible installation.

With the completion of improvements now under way, the possible capacity of the Greene-Cananea reduction works will be 6,000,000 lb. of copper per month. This is the statement of L. D. Ricketts, president and general manager of the Cananea Consolidated Copper Co., in the 1909 report, only recently issued and containing interesting details of Mexico's largest copper enterprise. A second reverberatory furnace is now building, and a battery of five additional boilers will be installed in connection with it; six additional McDougall roasting furnaces have been ordered; two additional 1200-kw. turbines are under contract, and the mines not yet equipped with electrical hoists and pumps will soon have them. The report shows that the 1909 production was 44,547,689 lb. of copper, 933,549.15 oz. silver, and 5877.468 oz. gold. A total of 1,016,536 tons was treated in the year, and the average copper recovery was 2.206%, silver 0.750 oz., and gold 0.0046 oz. per ton. The development during the year amounted to 46,911 ft. The total earnings from copper, silver, and gold, and net earnings from miscellaneous revenues, were $5,510,845.99, with total expenditures of $4,408,286.74, leaving net earnings for the twelve months of $1,102.559.25. The charge against the net earnings for depreciation of construction and improvements was $558,451.87, leaving a net profit of $544,107.38. The present management of the Greene-Cananea is striving for the highest possible efficiency at the minimum of cost, and every move made is with this in view. In 1909 the total cost of mining and beneficiating a ton of ore, including every item of expense until the refined product was sold, was $5.459, as against $5.976 during the six months of operation in 1908, $7.625 in the fifteen months preceding the shut-down at Cananea in October 1907, and $10.21 in the fiscal year 1905-6. The smelting cost per dry ton of new copper-bearing material was $3.09 in 1909, as against $3.86 in 1908, and $6.82 in 1907. However, the cost of producing a pound of copper last year was $0.116, while in 1908 it was but $0.105, but in 1909 the construction charge was higher than in the previous year and there was a big increase in development. The cost of mining was $2.22 per ton, an increase of 9c. over the cost in 1908, but of the sum 9½c. consisted of improvements and equipment installed and charged off, and the money spent in development amounted to at least 20c. per ton more than the same expenditure in the previous year. The introduction of fuel oil has been of great advantage to the Greene-Cananea, resulting in a cut of 50% in power expense per ton of ore. A concession for the free importation of fuel oil was obtained from the Mexican Government



Northern Portion of Sonora.

before smelting operations were resumed in 1908. Mr. Ricketts states that the power costs have dropped in the last two years from over $16 to under $8 per horse-power-month, and that a cost of less than $7, possibly not over $6, per month can be safely expected. Due to the fact of outstanding stock, the Greene-Cananea merger has not yet been perfected, and there exists some misunderstanding as to the present relations of the various companies. The Greene-Cananea Copper Co., the $60,000,000 merger concern organized by the Cole-Ryan interests, owns control of the Greene Consolidated Copper Co. and the Cananea Central Co., two American corporations. The Greene Consolidated, in turn, owns all the capital stock of the Cananea Consolidated Copper Co., the Mexican organization that has the smelter and other reduction works and the principal mines at Cananea, and 60% of the stock of the Sierra de Cobre Copper Co., the Mexican concern holding title to the Indiana-Sonora mines, purchased last year from the Phelps-Dodge interests. The holdings of the Cananea Central consist of all the capital stock of the San Pedro Copper Co., a Mexican holding concern; control of the Cananea Duluth Copper Co., an American concern, and 40% of the Sierra de Cobre. The Mexican holding company of the Cananea Duluth is the Cananea Development Co. If the merger is perfected the Greene Consolidated, Cananea Central, and Cananea Duluth will pass out of existence, the Greene-Cananea controlling all holding companies in Mexico.

The latest Mexico mine merger is one of much importance, concerning as it does the Mines Company of America, owning the Creston Colorado mines in Sonora; the Dolores Mines Co., operating the Dolores gold mines in western Chihuahua, and El Rayo Mines Co., with producing properties in the Parral district of the latter State. The merger plan calls for an increase in the capital of the Mines Company of America from $2,000,000 to $9,000,000, and the exchange of this new stock for stock of the other companies, 10 shares for each one of Dolores and 7 for each one of El Rayo. Dolores has 400,000 shares, par value $5, all of which stock is outstanding, and El Rayo 500,000 shares, par value $2, 352,000 shares of which have been issued. In 1909 the Mines Company of America paid in dividends $340,000, and the Dolores $462,896, and in the year ended with last October, El Rayo distributed to stockholders $137,089. Men interested in the U. S. Steel Corporation and the U. S. Realty Co. are principally interested in the Mines Company of America and the Dolores, while El Rayo is controlled by William B. Thompson and W. Hinckle Smith, of Philadelphia.

AUSTIN, TEXAS

Revision of State Mining Law. — Leasing System Probable for Coal and Oil Lands.

The demand for a revision of the Texas mining law, or rather the enactment of an entirely new measure, is so great among the men who are interested in bringing about the mineral development of the State that it is probable Governor Campbell will submit the subject to the legislature at its special session which will convene July 19. J. T. Robison, commissioner of the General Land Office, who has charge of the sale of the State's mineral lands, is urging the Governor to give the matter consideration, and it is stated that the latter has promised to do so. If the legislature acts speedily upon the specific matters for which it has been called, the subject of mining legislation will be submitted. Under the present law even the minerals upon the land sold for grazing or agricultural purposes are reserved by the State. This fact precludes prospecting or developing work being carried on by the present owners of the land or others. The statutes make no provision for the land owners buying the minerals upon their respective tracts of land, and an enormous amount of ground is therefore lying idle for want of an incentive to develop it. In order to further encourage the development of the State's mineral resources, Mr. Robison recommends that where the State owns mineral lands that have been sold to private individuals provision be made in the law for the prospecting of these lands by any person who may desire to do so in the event the person owning the land does not seek to develop the minerals thereon. He favors the operation of coal and oil lands on the royalty basis, the State to receive a certain percentage of the revenue obtained therefrom. He does not believe that it would be feasible to apply the royalty basis to gold, silver, copper, or quicksilver, and he advocates the State selling its title to these minerals outright. Mr. Robison is now employed in drafting a bill embodying his various suggestions, and it will be submitted to Governor Campbell for approval and recommendation to the legislature.

KALGOORLIE, WESTERN AUSTRALIA

Impoverishment of Ore with Depth. — Lake View Consols-Hannan's Star Consolidation.—Experiments with Wood Stave Pipes.

In consequence of poor developments in some of our mines the share market is depressed and there is anything but a satisfactory feeling. Diamond-drilling from the 1900-ft. level in the Associated has so far resulted in no payable ore being cut and ordinary stoping operations do not reveal much good ore. After making a loss for three months, a profit of $6800 was made during April. Only 60 men are now employed on the Associated Northern Blocks against 130 who were employed during the past six years. The mine may last for a few months longer. The South Kalgurli has a drop in its yield this month due to a temporary impoverishment of the stopes. The Lake View Consols profit is down. About $4200 of its usual profit comes from the retreatment of old dumps. The diamond-drill at the 2650-ft. level in the Edwards shaft of the Great Boulder, cut ore at 117 ft. west of the shaft, being 21 in. worth $5.04 per ton; and being about 5 ft. from the Golden Horseshoe boundary. At the main shaft, the west cross-cut at 2650 ft. cut ore 63 ft. from the shaft, being 6 ft. wide worth $3.48 per ton. These results are not very satisfactory, but further driving will probably open a better grade. The Ivanhoe publishes its ore reserves as 1,007,798 tons, averaging $10.96 per ton; the South Kalgurli 156,939 tons at $6.72; and the Golden Ridge 60,000 tons at $11.52 per ton. The Kalgurli is now sinking from 1750 to 1950 ft., and the Perseverance is also sinking to 2200 ft. from 2050. The Lake View Consols-Hannan's Star Consolidated amalgamation is now complete. The former has a 75-head mill, embodying concentration, tube-milling, bromo-cyanide treatment, and filter-pressing, while the latter has an out-of-date plant. The mines are not close together, being about one-half mile apart, so an aerial tram will probably be necessary to transport ore to the Lake View mill. As a result of an investigation into the prevalence of phthisis among miners in some of the northern goldfields, it is shown that the disease is not noticeable to any extent. Investigation in other districts will follow.

J. M. Maclaren's investigations on the rocks at Leonora and Day Dawn show that the greenstones in these localities contain gold in appreciable quantities, and should be actively worked. Producer-gas plants continue to be installed on many small mines on the goldfields with really fine results. The engines require a minimum of attention, and fuel costs are low. There is much rivalry between the various makers, the most prominent being the Crossley, Hornsby, National, Ruston Proctor, and Tangye.

The water used about the mines seems to corrode iron pipes very quickly, especially in the mills, where hot water is always in circulation for the roasting plants, etc. Trials of wood pipe, made by a firm in Sydney, New South Wales, are being started; and it would seem from experience in other places that, provided the outside of the pipe is protected, the water will not harm the inside in any way.

During April the principal mines yielded as follows:

Name	Tonnage	Value	Profit
Associated	11,575	$ 76,000	$ 6,800
Associated Northern Blocks	2,765	19,500	5,500
Chaffers	4,128	32,300	3,400
Golden Horseshoe	25,577	216,000	47,000
Golden Ridge	2,400	31,000	14,000
Great Boulder Proprietary	17,741	240,000	127,500
Great Fingall	10,561	78,000	11,500
Hainault	6,115	40,500	7,500
Ivanhoe	19,325	204,500	100,000
Kalgurli	10,760	140,000	76,000
Lake View Consols	9,850	66,000	7,000
Oroya-Brownhill	20,520	28,000	15,000
Oroya-Black Range	4,550	45,000	14,000
Oroya Links	11,186	75,000	16,500
Sons of Gwalia	13,492	116,000	46,500
South Kalgurli	9,270	52,000	4,200

BUTTE, MONTANA

Barnes-King Closed. — North Butte-Tuolumne Suit Started.

The Barnes-King gold mine at Kendall has been closed, and it is believed the last effort to secure any return for the money invested by the stockholders has been made. Stock can be purchased for less than 50c. per share, although it is estimated that with the cash in the treasury, amounting to something over $250,000, machinery, and other assets, it is worth about 53c. Three years ago the promoters of the Barnes-King came in for much abuse, and it was claimed that fully $400,000 was made by those on the inside in the purchase and flotation. Sellers Largey, president of the State Savings Bank of this city, recently sold at public auction 15,000 shares of Davis-Daly stock and 2500 shares of Mexican Consolidated Mining & Smelting Co. stock owned by J. A. Coram, which he placed in the hands of Mr. Largey to secure a loan, the total sum for which the stocks were held amounting to $101,000. The Davis-Daly stock brought $1.05 per share and the Mexican stock 50c. per share, so it will be seen that Mr. Largey's investment was not a very profitable one.

The long expected litigation between the North Butte Mining Co. and the Tuolumne Copper Mining Co., over what is known as the Jessie vein, has been started in the District Court at Butte by the North Butte company, which demands an injunction against the Tuolumne to stop it from mining on the Jessie vein anywhere outside of the little strip of jointly owned ground, and for an accounting of the ore taken out from the strip in question. In a voluminous complaint the North Butte company sets up its title to the Jessie claim and vein, and describes the various underground workings upon the vein to show the continuity of the body from the lowest workings to the apex within the side lines of the Jessie claim of the North Butte company. The complaint relates the points of controversy and says that unless a court of equity grants an injunction a great multiplicity

of suits will be necessary, and that even then the controversy could not be determined thereby. Therefore the court is asked to issue an order on the defendant company to appear and show cause why a temporary injunction should not be issued pending the final determination of the controversy. The court is asked to quiet the North Butte company's title to the vein and to decree that it owns the apex, but no preliminary restraining order is asked for. In a second cause of action the North Butte company sets up its title to a three-eighths interest in what is designated as the Jessie Strip, a long narrow triangular strip in the northeast corner of the Tuolumne claim, which was purchased by the North Butte from one of the original owners of the Tuolumne about a year ago, the Tuolumne company not having been aware of the fact that the interest was outstanding. The complaint relates that although the North Butte is a joint owner of that strip, the Tuolumne company has been mining it without the consent of the North Butte, and has taken out large quantities of ore since September 16, 1909. On March 26 last a demand for an accounting was made on the Tuolumne, and on April 18 a refusal was made, the Tuolumne at the same time denying the rights of the North Butte as to the Jessie Strip. The North Butte therefore demands an accounting through the courts, a judgment for its portion of the profits, and for a decree quieting its title to three-eighths of the Jessie Strip.

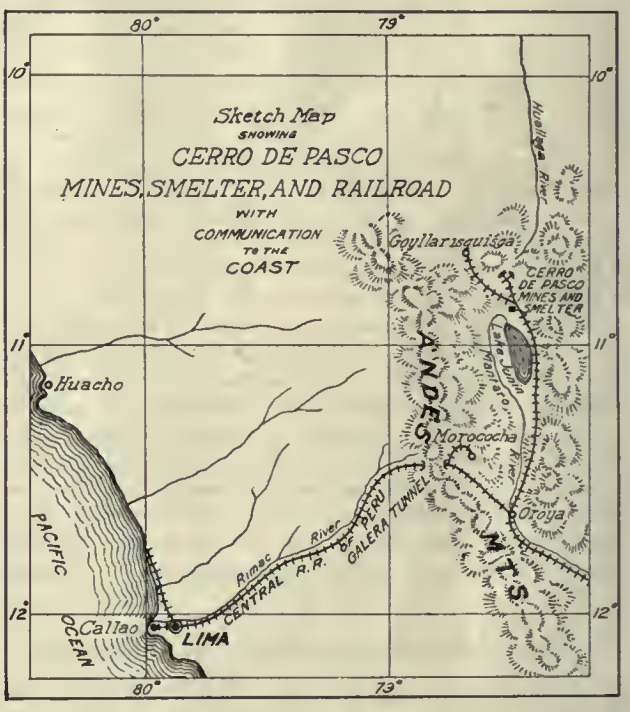
Stephen R. Dow, president, R. M. Edwards, general manager, and A. L. Wyman, secretary, of the Corbin Copper Co., are making an inspection of the property of the company, and advices from Wickes are to the effect that the officers are well satisfied with the progress being made in development. The 100-ton concentrator recently constructed is in operation and is doing good work. The Bonanza adit, at the mouth of which the mill has been built, has been opened into a fine body of ore and a winze recently sunk to a depth of 20 ft. below the adit-level, has opened a body of silver ore assaying over 150 oz. per ton.

NEW YORK

Shrinkage in Leading Stocks.—Arizona Copper Co.—Chino.—Ray Con.-Gila Merger.—Hedley Gold Mining Co. Stock Listed. — Cerro de Pasco.

The market condition here is becoming acute, the shrinkage in values is appalling. Granby, one of those that started the big declines in copper, sold down to $20 this week, as compared with its recent price of $112½. There are declines all along the line, the aggregate running into fabulous sums. Utah Copper sold at a high market of $66 last year; a recent low mark of $39⅜ means a market loss of $41,000,000 on its outstanding stock. The shrinkage in Amalgamated from its high mark of last year, $96½, as against a present low of $57, shows a loss in market value of $60,265,590. Taking the principal copper companies handled in the New York and Boston markets, comparisons between high marks of last year and the present low prices, the staggering total, in round numbers, is $335,000,000. In making this calculation only thirty-eight issues were included. How many times this total must be multiplied to cover the entire industry is beyond practical calculation. Whether or not a combination is being patched together is unknown, but the general impression is that war has been declared with the oft quoted proviso as to fighting along this line if it takes all summer. No important deals are known to be under way, though some little importance is attached to the presence of John Gill, of Edinburgh, in New York. Mr. Gill is chairman of the board of the Arizona Copper Co. He is accompanied by William Exley Miller, secretary of the board, and is thought to be negotiating further with J. D. Ryan, who desires to obtain the Arizona if the price can be agreed upon. Mr. Ryan and Mr. Gill were close to making a deal last February, when Mr. Gill was in New York, about the time the copper merger was thought to be completed. The deal was called off at that time because of the failure of the merger plans. The Arizona Copper Co. is known among engineers as the 'scrap heap' or the 'junk pile' on account of its antiquated equipment. It produces about 30,000,000 to 35,000,000 lb. annually which is sold by the United Metals Selling Co. With its plant rebuilt it would be an important addition to the chain of Cole-Ryan-Amalgamated Copper properties. Mr. Gill's presence in New York is said to be partly due to a contemplated plan for the erection of a new smelter to be owned jointly by the Arizona, the Shannon, and the Detroit. It is said that the officials of the three companies have been in consultation in reference to the plan. In view, however, of the well known fact that the Arizona is for sale and the further fact that the Phelps-Dodge company is amply prepared to treat all of the ores from the properties it controls, this story is thought to be mostly an excuse to hide the real negotiations which may be on.

The first annual report of the Chino Copper reveals some very modest claims as compared with the statements of Thomas W. Lawson, of Boston, made just after the com-



pletion of the deal which took the Santa Rita from his hands and converted it into the Chino Copper Co. The present partly and wholly developed ores amount to about 12,000,000 tons, the average copper content being 2.59%. Transportation is to be provided by the Atchison, Topeka & Santa Fe, with which road a contract is just being completed for the construction of nine miles of road to carry the ores from the mine to the mill. The output is expected to amount to between 35,000,000 and 40,000,000 lb. when the mill and plant are completed. Copper costs are figured at nine cents as a maximum. Good progress is reported in the Ray Consolidated-Gila merger. Of the 600,000 shares of Gila outstanding it is said that all of it has been exchanged save about 40,000 shares which is held abroad. The time in which to make the exchange has been extended thirty days to allow this stock to be sent in. The shares of the Hedley Gold Mining Co., which owns the Nickel Plate mines at Hedley, British Columbia, have been listed on the Boston Stock Exchange. The company has paid three dividends aggregating $108,000; it is controlled by officials of the United States Steel Corporation. The Cerro de Pasco Mining Co., of Peru, reports a production of 35,000,000 lb. for the year ending June 30. This company is backed by a group of prominent financiers, including J. B. Haggin, J. P. Morgan, H. C. Fricke, and the estates of D. O. Mills and W. R. Hearst. The Cerro de Pasco has cost its owners a great deal of money, estimated at possibly $20,000,000. The property is at present under the management of A. B. W. Hodges, who was formerly in charge of the Granby. Some stories are beginning to come down from Porcupine which have the ring of a boom camp. The Timmons shaft is said to be down 100 ft. with the richest ore yet discovered in the bottom of the shaft.

General Mining News

ALASKA

(Special Correspondence).—Shipments of ore from the mine of the Mt. Andrew Iron & Copper Mining Co. have aggregated 55,000 tons. They now amount to 2500 tons per month to the smelter at Ladysmith, British Columbia. The ore samples 50% magnetic iron, 5 to 6% copper, 3½% lime, and 8 to 10% silica. It was formerly believed that the Mt. Andrew had a blanket vein, but development in the last year has demonstrated that the orebody, first opened on the 60-ft. level, is equally strong in width and grade at a depth of 185 ft. Much of the ore being shipped now is taken from the 150-ft. level. The ore is so even in its iron content, as well as copper, that a ready market is afforded. It is said there will be bids on this ore for one of the Utah smelters.

Alaska.

The marketable copper-iron ore is found here in bodies as wide as 150 ft. below an iron cap. The property has two steam boilers, two air-compressors, and a hoist which is operated by compressed air. The ore is transported from the mine to the ore-bunkers over a 3600-ft. aerial tramway, by which 200 tons per hour can be delivered. Henry Ballou, formerly of Butte, became superintendent last May. M. D. Haynes and S. Lichtenstadter of Seattle are among the most heavily interested in the company. There are 127 men on the operating force.

Ketchikan, July 9.

ARIZONA

COCHISE COUNTY

Four feet of ore assaying about 10% copper shows in the face of the drift on the 120-ft. level of the Whitetail at Paradise, the drift having been run 45 ft. from the shaft. In the east drift the ore is 6 to 18 in. wide and is lower in grade. ——A small force had been started at the Bermoudy.—— In the face of the cross-cut at the 110-ft. level of the shaft on the Cummings and Walcott claims near Courtland, a 4-ft. vein of lead-silver-gold ore has been opened.

MOHAVE COUNTY

The shaft at the C.O.D. mine is expected to reach the 300-ft. level in a few days when drifts will be started to block out the ore on that level.——The smelter at Needles received a carload of high-grade ore from the Redemption recently. ——Nine tons of ore shipped to the smelter by Robert S. Roe from his property in the Weaver district assayed 29% copper with a high silver content. Another lot is on the dump at the mine and will be forwarded in a short time. ——Construction on a 900-ft. spur from the Western Railway of Arizona to the town of Mineral Park is under way, and it is understood that it may be built to Mineral Park canyon, where an ore-bin will be erected.——The drift on the 150-ft. level of the Keystone mine is being driven west into new ground and it is now in the best ore found on the property.

PINAL COUNTY

The Copper Queen Consolidated Mining Co. of Bisbee has secured a bond on the Maverick group at Florence for $100,000. The option runs for one year and during that time the company is to sink two shafts with suitable development on the ore. If the property proves satisfactory the bond calls for the payment of the purchase price in three installments of $10,000, $20,000, and $70,000. The orebody is reported to be several thousand feet long and about 300 ft. wide, the ore being a disseminated chalcocite that assays about 3% copper with occasional streaks of high grade.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence).—The reopening of the Lincoln mine, at Sutter Creek, will be watched with great interest by all mining men on the Mother Lode. The mine in its early history was famous, producing $2,500,000 to a depth of 350 ft. at which point the rich orebody was cut by a fault, and the downward continuation of the vein has never since been found, although the shaft was sunk to a depth of 2000 ft., and thousands of feet of driving and cross-cutting has been done. There is a difference of opinion among those familiar with the mine as to the probable position of this ore-shoot below, some believing it to lie to the eastward, while others think it is in the west country. Geological indications point strongly to the west as the probable region in which it will be found.

Sutter Creek, July 11.

CALAVERAS COUNTY

The adit at the Peck ranch near Mokelumne Hill has opened a vein of free-milling ore.——The 40-stamp mill which the Utica Gold Mining Co. is building at the Golden Cliff mine at Angels Camp is rapidly nearing completion and will be in operation in a short time.

MODOC COUNTY

Brown & Bassler have installed a whim at their Big Four lease in the Hoag district and are sinking on ore that assays $20 to $40 per ton. They have just completed a wagon-road to the new Wall mill and will soon be shipping their ore.——McClearly & Schauer have opened a $60 shoot on the Mountain Sheep claim.

NEVADA COUNTY

Special Correspondence).—F. O. Parker, representing the Golden Eagle Gold Mining Co. of Los Angeles, has purchased the Mitchell claims on Deadman flat, and a half-interest in the West Point mine. The West Point adit will be retimbered and driven ahead. It is also planned to sink a central shaft to a vertical depth of 500 ft.——James Neal of Butte, examined the Polar Star, adjoining the North Star properties, last week, and is understood to be considering the resumption of activities.——The North Star Mines Co. is working on its holdings on Cincinnati flat, in addition to the regular development.——The California stockholders of the Black Bear Mining Co., owning property near Grass Valley, have commenced suit against the company for the return of 150,000 shares of stock, claimed to be illegally held.——The Champion Gold Mining Co. has filed suit against the Champion Mines Co. to recover the property, also for damages amounting to $50,000. The plaintiff company is composed of Chicago men, and was dispossessed last spring, following a dispute regarding the question of payments on the bond.——A shoot of milling ore has been opened near the 400-ft. level of the Prescott Hill property of the Sultana group.

Grass Valley, July 13.

Samples of the ore at the bottom of the 90-ft shaft at the Lucky Star mine near Rough and Ready assayed about $15 free-milling gold with considerable concentrate. There are nine men working at the property and good progress is being made in the shaft which is being sunk on the vein. The ore has averaged four feet in width.——The new compressor at the Fruitvale mine at Moores Flat is being installed at the plant and will be ready to run by the first of August. There is a large vein in the face of the adit and

the installation of the compressor will be of material aid in development.

PLACER COUNTY

There are about 40 men on the payroll at the Big Dipper group. The old mill has been put in good running order and is handling gravel drawn from chutes No. 15 and 16. ——A new mill is being erected at the Brun mine.——Work was suspended at the Hidden Treasure for a few days on account of a cave.

SHASTA COUNTY

The Mammoth Copper Co. at Kennett has completed the bag-house that is designed to destroy the smelter smoke, and resumed operations. The structure is 250 ft. long and 75 ft. wide, and divided into five compartments each containing 600 bags. These are 30 ft. long and have a diameter of 18 in. Two 400-hp. motors will be used in operating the plant.

SIERRA COUNTY

The Independence mine on Wolf creek three miles east of Alleghany has been bonded to a group of Eastern capitalists. The Independence is one of the old mines of this portion of the county and was a profitable enterprise in early days. The shaft will be unwatered, and a new hoist and pump installed.——J. D. Beggs, manager of the Kate Hardy, brought three sacks of ore valued at $1000 to Forest from the rich shoot that was opened a short time ago.——Owing to the failure of the brakes on the hoist at the Alaska mine near Pike City the skip was dropped from the 400-ft. level to the bottom of the shaft killing two miners who had started to the surface.——The last payment of $10,000 on the bond of the Bear Creek mines was made in Alleghany a few days ago by J. W. Evans and associates.——A crew of men has been put to work at the Bullion mine near Sierra City which was bonded recently to Charles R. Thompson. ——At the Carson mine in Slug canyon sinking has been resumed in the bottom of the 30-ft. shaft. A drift was run at this point opening free-milling ore.——A gasoline engine has been installed at the Uncle Sam mine above Forest, and the shaft is being unwatered and retimbered.—— Charles Brown has secured a bond on the Watson claims in Coyote canyon.——The drift on the vein at the Tightner opened a shoot of high-grade ore portions of which are almost pure sulphide at a distance of 400 ft. from the adit.

TRINITY COUNTY

A 7-ton motor truck has been installed to haul the freight from Delta to the Headlight mine at Carrville. Up to this time all freighting has been done with teams and the installation of the truck is expected to cut down expense and hasten the work.——The Larsen brothers have commenced work at the Quimby mine in the northern portion of the county and are erecting a cyanide plant to treat the pulp from the 30-ton mill.

YUBA COUNTY

The Natomas Consolidated Gold Dredging Co. has commenced work on the new construction camp on the Yuba river where it will build the largest dredge in the world. The hull will be five feet longer than that of the Natomas No. 8 which is 150 ft. long and carries a chain of buckets having a capacity of 13½ cu. ft. each. The new boat will be known as the Natomas No. 13 and carry the same size buckets as No. 8.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—The new buildings at the Homestake property on Lincoln mountain have been completed and a contract will be awarded to drive the adit 100 ft. farther. A. L. Stephens the manager is preparing to start the construction of a milling plant that will have an initial capacity of 25 tons per day.——Machine drills were brought into use last week by the Clear Creek Mining & Leasing Co., which is putting through a raise on the Frostberg vein to connect with the upper workings. There remains 250 ft. of ground to be broken.——The mill at the Wilcox adit in East Argentine district was temporarily closed July 1. A number of improvements are to be made in the adjustment of the machinery. The Chilean mills are to be taken out while a set of rolls will be provided.—— David Kennedy, owner of the Brazil mine at Freeland, has started development. The lower adit is to be driven ahead as a small streak of high-grade ore is exposed.—— Machine drills are to be brought into use at the Hoosac adit, situated on lower Fall river. E. T. Quigley of Denver has been appointed manager.——A 240-ton shipment of ore recently made from the Refugee mine to the Hudson mill resulted in a clean-up of 107 oz. gold from the plates, as well as 30 tons of concentrate that brought $1200.

Idaho Springs, July 10.

GILPIN COUNTY

(Special Correspondence).—Large development is in progress at the Baxter mine on Quartz hill. Operations are being centered on the 100 and 200-ft. levels, shipments of both mill and smelting ore being maintained.——Development is in progress on the Ashtabula property situated in the Nevada district. A new shaft-house is in course of construction, while a 50-hp. boiler and a 25-hp. hoist has been purchased. W. T. Wells is manager.——Work was resumed on the Rockford mine in Russell district. Lowe & Harris, the owners, state that the shaft will be sunk another 100 ft. ——The south vein of the Gunnell mine has been intersected by the Newhouse tunnel.——Heavy shipments have been in order during the past two weeks by Shearer & Co., who are leasing on the Old Town mine. The product is sent to the Golden pyritic smelter, but no settlement has yet been effected.

Central City, July 12.

LAKE COUNTY

Chloride ore in considerable quantity has been opened at the Anona property on Long and Derry hill by H. B. Collins and Tony Hurn, the drifts have been started in the hope of opening a continuous orebody.——A company composed of Denver capitalists has secured a bond on the Fourth of July claims in Big Evans gulch and will sink a shaft to prospect the ore.——Work has been resumed by George F. Champion on the Little Bob property and the adjoining Volunteer will be prospected from the bottom of the Little Bob shaft.——St. Louis interests have secured a lease on the north 750 ft. of the Fanny Rawlings, and the shaft is being unwatered and retimbered.——Stoping is in progress on both sides of the Highland Mary shaft and 30 tons of ore per day is being shipped to the smelter.——Local operators have secured a lease on the President claim and started cleaning up the property.

OURAY COUNTY

Joseph H. Tumbach, manager for the Colorado Smelter Co., has taken possession of the pyritic smelter north of Ouray, and it is reported that the plant will resume operations. This will mean much for the properties of that district as it is only possible for a number of them to run when local treatment can be obtained.——The Guadalupe at Ironton has been put in shape for active mining, and shipping will be resumed in a short time. There is considerable high-grade copper-silver ore blocked out in the mine.——Arrangements have been completed for the resumption of work at the Micky Breen in the Poughkeepsie district.

TELLER COUNTY

An 8-ft. vein assaying from $40 to $50 per ton has been opened on the 800-ft. level of the Golden Cycle Mining Co. on the Legal Tender claim. The company is now installing a 30-drill Ingersoll-Rand compressor.——The Modoc Mining & Milling Co. is continuing development and shipping considerable ore from the old Frakenburg vein. Plans are now in preparation for the installation of a mill patterned after the Portland plant.——John Kilday is shipping ore that assays about $30 per ton and screenings that go as high as $275 from his lease on the sixth level of the Blue Bird mine.——Ore assaying $40 per ton was opened within 10 ft. of the surface on the Last Dollar claim by sub-lessees.—— The Roosevelt Deep Drainage Tunnel was advanced 373 ft. during June, leaving 570 ft. still to reach the El Paso shaft. ——The new machinery is being installed as rapidly as

possible at the Cresson and work has been resumed in the mine.——A new 4-drill compressor has been installed at the Jefferson and operations resumed on a larger scale by the Strong Extension Mining & Leasing Company.

GEORGIA

MC DUFFIE COUNTY

Leo Von Rosenberg who is consulting engineer for the Columbia Mining Co. has made arrangements to subdivide a large amount of the land owned by that company into small parcels and open the ground to prospectors. The land thus prospected may be purchased after mineral has been discovered, held by lease and the ore treated at the company's mill on a royalty basis, purchased outright, or worked on percentage. The company will determine the size of shafts, workings, and methods of timbering.——The management of the Hamilton mine situated in the same district will sink a new working shaft. W. H. Fluker is manager.——Operations will also be resumed at the Columbia mine and the mill enlarged. The shaft is now down 450 feet.

IDAHO

BLAINE COUNTY

In the Wood River district the Nay-Aug Idaho Mines Co., of which W. W. Chambreau, of Portland, is manager, has succeeded to the ownership of the Nay-Aug mine, having purchased the interest of the Wood River Zinc Co. in the property. The Nay-Aug is an old mine, having been operated in the eighties. It is situated on Deer creek, ten miles from a railroad siding between Hailey and Ketchum. The principal vein is in granite, and the latest development has been from No. 7 adit level, on the vein. This adit has served for transportation and drainage; it gives 700-ft. depth, and the plan is to extend it 300 ft. farther. A raise will be made 270 ft. from this adit level to connect with a shaft. It is also intended to sink a winze from the adit. The orebody in the vein is from 10 in. to 2 ft. wide, the ore assaying 50% lead, 65 oz. silver, and 0.3 oz. gold. The company is spending $35,000 on development and equipment, the latter including a hydro-electric power-plant, situated one and one-half miles from the mine on Deer creek; also a hoist, air-compressor, and air-drills. W. S. Haskins was recently engaged as superintendent, and is now in charge. The company has five patented claims.——The Croesus mine and mill, three miles west of Hailey, belonging to the Croesus Gold & Copper Mining Co., and under the management of S. E. Rigg, is shipping five carloads per month of first-grade ore and concentrate.

IDAHO COUNTY

The Elk Mines Corporation is to install a boiler to supply power for the 5-stamp mill at the South Fork mine in the Elk City district, and thoroughly overhaul the plant.——The adit at the Cumberland is now in 50 ft. and is expected to cut the vein within the next 30 ft. The company is to install a power-plant and a machine-drill.——George H. Jennings, who is developing the Hope claims two miles east of Elk City under lease and bond, is opening ore in the bottom of the shaft that assays about $50 per ton.

SHOSHONE COUNTY

The Bullion Mining Co. will begin shipping from its mine, between St. Regis and Wallace, early in September, according to James H. Taylor, secretary and treasurer of the company, now in Spokane. He also announced that a 5-drill air-compressor will be installed at that time and that it is purposed to add a small mill early next spring. The company is to install jigs to concentrate the ore already taken out. The main shaft is down 180 ft., or 50 ft. below the main adit-level, with which it is connected. The workings on that level have opened two shoots of chalcopyrite ore.——John Winkle, president of the Idora Mining Co. and B. F. and S. E. Knudtson of Spokane, will begin work on the O. K. property in the St. Regis district early in August. August Paulsen of Spokane, one of the owners of the Hercules mine in the Coeur d'Alene district, has undertaken to finance the Puritan mine in the same neighborhood, and the property will be opened at once.

KANSAS

CHEROKEE COUNTY

(Special Correspondence).—The Galena camp is busier for the present time than it has been for several years. Among the most prominent recent developments are those on the Glick land. On this land Mr. Savage and associates have opened one of the best deposits found in years. One shaft sunk to 80 ft. opens a 20-ft. deposit of lead ore. At a short distance a second shaft is down 90 ft., the ore face in this being 30 ft. high. In this the ore is zinc and assays from 10 to 25%. The ore is being treated at the old Bonanza mill which has been leased by the company.——To the west of this land the Rohrbaugh brothers have opened a zinc run at 60 ft. which is proving freer in character than that found in the Savage shaft. Four drill-holes have been sunk, two of which cut rich ore.——The recent heavy rains caused Short creek to overflow and the shafts and drifts on the Lockport land were flooded to the surface. All workings below 20 ft. had to be suspended and the pumps have been heavily taxed to overcome the water. A new centrifugal pump together with an Emerson and two walking-beam pumps will all be used.——The large plant of the Diplomat company is almost completed and will be run by electricity. The mill was formerly the Lizzie D. moved from the Peacock district. There are at least 4000 tons of unsorted ore to be treated by the mill.

Galena, July 9.

MICHIGAN

The directors of the Osceola Consolidated Mining Co. have declared a semi-annual dividend of $4 per share. The dividend declared six months ago was $6 and and a year ago $4. Osceola dividend is payable July 28 to stock of record July 5. The declaration of $4 per share calls for the distribution of $396,600 and makes a total of $8,980,650 paid in dividends since the organization of the company. The following is a dividend record of the company since its organization:

Year	Rate	Amount	Year	Rate	Amount
1878.....	$1.00	$ 40,000	1895.....	$ 2.00	$ 100,000
1879.....	1.50	60,000	1896.....	2.50	125,000
1880.....	4.50	210,000	1897.....	3.00	191,000
1881.....	4.50	225,000	1898.....	3.00	277,250
1882.....	4.00	200,000	1899.....	6.00	558,450
1883.....	3.00	150,000	1900.....	6.00	571,200
1884.....	1.75	87,500	1901.....	6.00	576,900
1887.....	1.00	50,000	1904.....	2.00	192,300
1888.....	3.00	150,000	1905.....	4.00	385,600
1889.....	1.00	50,000	1906.....	10.00	961,500
1890.....	4.50	225,000	1907.....	13.00	1,249,950
1891.....	3.00	150,000	1908.....	2.00	192,300
1892.....	3.00	150,000	1909.....	8.00	769,200
1893.....	2.00	100,000	1910.....	10.00	973,509

NEVADA

CLARK COUNTY

The Homestead Mining & Milling Co. has given up its option on the Duplex ground and the property has reverted to the original owner, G. Fred Colton. Operations will be resumed on the ground by Mr. Colton and a large amount of development carried forward before any attempt at stoping is made. Over $300,000 worth of ore has been taken from the mine at various times.——Smith & Fessler who hold a lease on the I.X.L. ground recently ran 15 tons through the Knight mill from which they obtained a 41-oz. bar of gold.——The Square Deal Mining Co. is to install a new hoist and will commence sinking within the next few months. J. F. Booth is superintendent.——A 50-ton mill is to be installed at the Nevada-Eagle mine in Eldorado canyon. The return on a lot of test ore shipped recently amounted to $23 per ton, the ore showing no complex features. The plant will be only for amalgamation and concentration.——The concrete foundation for the Independence mill has been completed and the stamps will be installed at once.

CHURCHILL COUNTY

A number of properties in the Wonder district have added

to their working forces since the ground for the Nevada Wonder mill has been broken.——Notices of a special meeting of the stockholders of the North Star and the reorganized Alice Mining Co. to be held in Goldfield July 18 have been sent out, and these companies will elect new directorates and arrange for further exploration on the properties.

ESMERALDA COUNTY

The 100 stamps of the Consolidated mill at Goldfield are now dropping for the first time since the fire several months ago and the output from the plant should be increased about 20%.——The Combination Fraction Mining Co. has ordered a new tube-mill, classifiers, and other equipment for the plant of the Nevada Goldfield Reduction Co. and is treating 70 tons of ore per day.——The Morrison lease on Daisy ground is producing about six tons per day of $25 ore.——It is reported that the Goldfield Belmont will resume work on its property in the Diamondfield district on company account. The owners are keeping the water out of the Burke lease workings and the operations of the lessees in this portion of the mine have led the company to believe that a continuation of the shoot may be opened farther on.

LANDER COUNTY

The adit of the Pittsburg-Red Top in the Kimberly district opened the vein when in approximately 600 ft. showing it to have a width of 12 ft. Between 7 and 8 ft. of the ore is a concentrating material, the balance, smelting. The property is owned by the Kimberly Consoldated Mines Co. ——L. G. Sands who has a bond on the Grey Eagle has driven the drift 200 ft. on the vein and is opening a body of smelting ore.——A body of $15 ore is being opened on the Fuller & Mason group which is being worked under bond.

LINCOLN COUNTY

Fred Falkner, receiver for the Bamberger Delamar Mines Co. has sent out notices that the property of the company will be sold at public auction at Caliente September 13. The outfit to be sold consists of electrical equipment, hoists, air-compressors, and other machinery.——The Consolidated Pioche Mining Co. has retimbered the portions of the shaft that were in need of repair and is sinking from the 1200-ft. level.——The mining situation in the Pioche district has improved materially since the re-establishment of the railroad service, and a number of the properties are shipping ore and concentrate. Teams are hauling ore from the Mendha mine to the depot, and a carload of Mendha ore with a car of concentrate from the Poorman lease were forwarded to Salt Lake.——George Coxe, manager of the Golden Prince, has returned and is preparing to sink to the 700-ft. level.

NYE COUNTY

(Special Correspondence).—Development on the 1000, 1108, and 1166-ft. levels of the Belmont have exposed from 10 to 20 ft. of ore said to average $10 per ton. The east drift on the 1108-ft. level is about 40 ft. south of the new Belmont shaft and has opened 12 ft. of ore for over 300 ft. A carload of ore per day is being shipped in addition to the amount handled by the mill.——The MacNamara management has decided to install a diamond-drill on the 800-ft. level and explore the property to a depth of 1000 ft. below this. A large body of low-grade ore has been opened at this point.——The shaft of the Mizpah Extension has been repaired and sinking is progressing from the 800-ft. point. It is planned to drive south cross-cuts as soon as the shaft has attained the 1000-ft. level.——Machinery for the new mill of the Tonopah Liberty mine is arriving. T. S. Carrahan, general manager, reports good ore opened at several points.——The bullion return of the Round Mountain Mining Co. for June is $28,000 which is a little below the average. This is due to the fact that the company handled a large amount of low-grade ore preparatory to the installation of new machinery and development. The new plant is being hauled to the mine and will be installed within the next two weeks, when the ore from the eastern portion of the property will supply the material for the mill.

Tonopah, July 10.

WHITE PINE COUNTY

The station at the 1200-ft. level of the Alpha shaft of the Giroux Consolidated in the Ely district has been reinforced with concrete and when the pumps are installed cross-cutting to the east will be started. The station is 125 ft. long and 25 ft. wide, and the pumps will have a combined capacity of 1800 gal. per minute.——At the Nevada Consolidated everything is ready for the opening of the Liberty steam-shovel pit west of the present workings on Copper Flat. Two steam-shovels and three locomotives will constitute the initial equipment, the track for which is now being laid.——Four feet of copper ore has been opened in a winze from the adit on the North Star claim of the Ely Calumet which is leased to F. A. Strelhke. ——The main shaft of the Ely Central will be down 550 ft. in a few days and drifts will be started to explore the ground that adjoins the Nevada Consolidated.——There are 200 tons of ore on the dump of the Kinsley Consolidated that will be forwarded at an early date to Salt Lake.—— Work has been started at the property of the Bowen-Ely Gold Mines Co. and the vein will be opened in several places. W. N. Bowen is manager.——Johnson & Hastie, who have been operating the Sun & Moon claims under lease and bond for the past few months, have recently shipped a carload of silver-lead ore that is expected to net $30 per ton. ——Salt Lake interests have secured a bond on the claims of Thomas G. Watkins in the Blackhorse district for $37,000 and the deeds to ground have been placed in escrow in Salt Lake.——The Ohnana Mining Co., which owns a group of claims near Osceola, has completed plans for a 20-stamp mill and ground for the new structure will be broken within the next two months.——A raise in the main workings of the Minnesota Lead Co. on Duck creek opened a body of galena ore and teams have been started hauling the product to the McGill siding from which point it will be forwarded to Salt Lake.

NEW MEXICO

SIERRA COUNTY

(Special Correspondence).—Schiele, Chapman, and associates of Colorado Springs have exercised their option upon the Ivanhoe property in the Black range, and the first payment has been made, Kansas City interests providing the financial backing. It is understood that active operations will begin soon, with Mr. Chapman in charge at the mine. This property has the deepest shaft in the district, and the ore is chiefly bornite.——A large force of men is making rapid progress in the reconstruction of the old Phillipsburg mill. Portions of the old machinery, available for use with the new process, are retained and new machinery necessary to complete the plant will be installed. The operating company is the Black Range Reduction Co., which purchased the old mill and mill-site, and which owns considerable mining property in the district. In addition to treating its own ores, the company expects to do custom work, for which there is a distinct field here. The camp has many immense deposits of milling ore which can be made to yield a profit under local treatment, but which do not justify shipping under existing conditions of transportation. It is understood that the Black Range Reduction Co. will be prepared to receive ore within 90 days.—— Recent sampling of the workings at the 200-ft. level of the U. S. Treasury mine shows general conditions to be much better than they were at the 100-ft. level. It is understood that the sampling shows a general average of close to $22 per ton. The company is concentrating its work in the opening and blocking out a large tonnage in anticipation of the early erection of its own treatment plant.——The Silver Monument operators, after a long and practically barren line of development, have struck some fine ore, the first high grade they have found since beginning their long adit. It contains chalcopyrite, bornite, and native silver.

Chloride, July 11.

GRANT COUNTY

It is expected that the Chino Copper Co. will have its new mill plant, now in course of construction, completed

within a year. The steel has been bought, and some deliveries are being made at the site on the Santa Rita branch of the Santa Fe railroad. D. C. Jackling general manager is at the property now, and a day and night force is engaged in building a concrete dam across the arroyo below Holson's ranch, for impounding of flood water. A considerable tonnage of developed and partly developed ore is being added to the reserve of this mine each month. There is a large amount of ore on the property proved up at this time, and it is learned that at least 40% of this tonnage can be mined by steam-shovels. Some stripping of the steam-shovel territory has been started, and by the time the mill is in operation there will be ample ore exposed to feed the plant for a number of years to come. The initial capacity of the mill is to be 2500 tons per day, but it is understood that this capacity may be increased within a short time after the plant is started.

UTAH

BEAVER COUNTY

The Arrowhead Mining Co. in the Arrowhead district is driving its lower adit to open the shoots found near the surface and preparing the upper levels for a large production.——The King of the Hills mill is now turning out concentrate that assays 42% lead, 10% copper, and 10 oz. silver per ton.——The Cupric Mines Co. which owns 16 claims four miles northwest of the Horn Silver mine is working about a dozen men on the 400-ft. level and driving on the ore. The shaft is sunk on the contact between granite and a limestone and has cut a number of pockets of rich copper ore.——The Horn Silver is shipping from 1000 to 1500 tons of ore per month and working about 75 men. A small pocket of ore was opened a short time ago on the 700-ft. level that assayed from 300 to 800 oz. silver per ton.

JUAB COUNTY

At a recent meeting of the board of directors of the Mammoth Mining Co., an assessment of 10c. per share was levied.——The Chief Consolidated is raising above the 1400-ft. level on ore that assays 200 oz. silver per ton. The report of the general manager to the home office at Houghton states that a profit of approximately $41 per ton was made on an 11-car shipment, and that the company earned a profit of $20,000 for the month of June.——Work at the Eagle & Blue Bell is centered on the main shaft which is down over 275 ft. No effort is being made to crowd production but from 16 to 18 carloads of high-grade ore per month is being shipped.

SUMMIT COUNTY

The zinc plant at the Grasselli is proving more of a success every day by sending out increased shipments of zinc concentrate. The Daly-Judge and Daly West are both shipping considerable zinc, that material now proving an asset to the properties rather than a drawback as it has been considered in the past.——At a meeting of the directors of the First National Mining Co. recently it was reported that the adit is in 150 ft. and is expected to open the fissure within the next 150. The cash from the last assessment is all in and there is a surplus in the treasury that should be sufficient to drive the present workings to their limits. ——Shipments of high-grade ore from Park City during the month of June amounted to 7893 tons. Daly West leads the list with nearly 3000 tons, while Daly-Judge is a close second, with Silver King in third place. June shipments were as follows:

	Tons
Charles Moore	171
Frank Hamer	18
Daly-Judge	2,200
Chris Anderson	128
Little Bell	360
Grasselli Chemical Co	946
Daly West Mining Co.	2,738
Daly Mining Co.	34
Silver King Mining Co.	1,219
Total	7,893

UINTA COUNTY

The Mitchell dredge on Green river 15 miles southeast of Vernal is working on gravel that varies between 60c. and $2.25 per cu. yd. In the same district John K. Bullock has incorporated a company to take over the Arnold and McHughs placer claims.——Twelve miles west of Vernal there are indications of oil and a rig has been shipped to that district to drill a number of holes on a royalty basis.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—The Copper Creek Mining Co., for which M. K. Rodgers, of Seattle, is manager, is estimated to have 1,000,000 tons of ore exposed by 2000 ft. of open-cut work and a 1500-ft. adit. The ore is said to assay 3 to 3½% copper, carrying an excess of iron. It is a self-fluxing sulphide ore. A 2000-ft. gravity tramway and a one-mile electric car line, over which the ore is to be transported to the water-front on Portland canal, are partly constructed. Mr. Rodgers thinks the company is practically

Copper Creek Mine, Portland Canal District.

ready for a smelting plant.——The Engineer's group at Atlin has a vein of gold-bearing ore, some of which assayed $5000 per ton. The larger part of it is of milling grade and the owners of the property have installed a 10-stamp mill for crushing, amalgamating, and concentrating. The fact that there is an abundant water-supply in Atlin district makes it certain that the hydraulic placer mine operators will have a full season's run and profitable clean-ups.——A syndicate has been organized at Vancouver to purchase the Ikeda copper mines, situated on Morsby island, 500 miles from Vancouver. This property is generally known as the Japanese mines. Ore shipped brought about $60,000. The main vein has been opened and considerably developed by an adit-level that gives a depth of 300 ft. A second vein, parallel to the first one, has also been opened. The ore consists of chalcopyrite, much of which assays unusually high in copper. The syndicate which contemplates taking over the property is made up of S. J. Castleman, W. H. Armstrong, Mr. McClellan, and associates. Andrew G. Larson, consulting engineer for the syndicate, recently examined the property.

Vancouver, July 11.

ONTARIO

The fifth shipment of ore from the Beaver mine in southeastern Coleman has been forwarded to Carnegie, the average assay being 116 oz. silver per ton. There was 30 tons in the lot, which brought the total for the year to 90 tons. The ore was drawn from the stopes on the 250-ft. level of the winze.

YUKON TERRITORY

Greenough Brothers, of Spokane, who have taken over the Pueblo group of copper mines at White Horse, are to begin the shipment of 200 tons of ore per day to the Tacoma smelter about August 1. The ore is said to carry 3 to 4% copper, accompanied by a high percentage of hematite. A railroad track from White Horse to the mines has been finished.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

OWNERSHIP OF SURFACE AND MINERALS

It is a well settled principle of mining law that one person may own the surface and another the minerals in the same land. It is also the rule that title to the freehold of either the surface or minerals thereunder cannot be acquired by adverse possession of the other.

Morrison *v.* American Assn. (Va.) 65 S. E. 469, Sept. '09.

INJURY TO MINER—NEGLIGENCE

In an action by a miner for damages for an injury where it appeared that props for the roof of a mine allowed a clearance of not more than three or four inches for the cars ordinarily used, this was sufficient to warrant an inference of negligence.

Golden *v.* Mt. Jessup Coal Co., (Pa.) 73 Atl. 1103. June '09.

LEASE OF COAL—RECOVERY OF RENTALS

A lease of coal for ninety-nine years stipulated that the lessee should pay a stated minimum royalty, but neither the lessee nor his assignee ever took possession of the coal under the lease or performed any of its covenants. In an action by an assignee of the lessee to recover the coal in a suit in ejectment, the Supreme Court of Montana decided that he could not recover without paying the minimum royalties then in arrears.

Cornely *v.* Zentmyer, (Pa.) 73 Atl. 967, May '09.

INJURY TO MINER—FELLOW SERVANTS

A mine-boss and a fire-boss employed in a coal mine, pursuant to the statute of West Virginia and in the performance of the duties thereby imposed upon them, including the duty of the mine-boss to see that as the working places advanced 'break-throughs' for air are made, or that 'brattice' shall be used, were held to be fellow servants with a miner employed in such mine, and that the owner and operator of the mine was not liable for injuries sustained by the miner on account of the negligent performance of such duties by the mine-boss.

Brailey *v.* Tidewater Coal & Coke Co., (W. Va.) 56 Southeast. 684, Jan. '09.

CONSTRUCTION OF GAS LEASE—CANCELATION AND FORFEITURE

An oil and gas lease gave to the lessee the exclusive right to produce oil and gas from a certain tract of land. The lease provided that if a well was not drilled upon the premises within one year, the lessee's right should cease. The lessors were to have gas for domestic use, if found in quantities sufficient to justify the expense of marketing, and were to be paid $50 per year during the time gas should be marketed from each producing well. One well was completed within the year. The lessors were given sufficient gas therefrom for domestic use, and the lessee also used it for fuel in drilling; but no other use was made of the well, no gas was sold; no other wells were drilled, and the lessors never received anything except the one dollar, the consideration in the lease, and such gas for domestic use. Several other gas wells were drilled on adjacent lands by the lessee and by other parties, some of which yielded gas sufficient for marketing. More than four years after this well was completed the lessor served notice of forfeiture and commenced an action to cancel the lease. On the trial of the case it was held that the lease contemplated that the well should be operated and gas marketed therefrom in a reasonable time, and that other wells should be drilled and operated with reasonable diligence to utilize the lease; that four years' delay under the circumstances was unreasonable; that the lessors had no adequate remedy in damages and were entitled to have the lease forfeited and canceled.

Howerton *v.* Kansas Natural Gas Co., (Kans.) 106 Pac. 47, Jan. '10.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

GEORGE J. YOUNG is at San Francisco.

E. B. KIRBY is at Los Angeles, California.

J. H. RODGERS, of Seattle, has gone to Alaska.

E. E. ELLIS is at Evanston, Illinois, temporarily.

E. F. BURCHARD is at Glennwood Springs, Colorado.

CHARLES KIRCHHOFF is enjoying a vacation in the Tyrolese Alps.

LEWIS T. WRIGHT has returned to San Francisco from London.

JON UDDEN is with the T. C. I. & R. Co., at Birmingham, Alabama.

W. S. NOYES is making a short visit to Sierra county, California.

THOMAS A. JAGGAR, Ja., is in Costa Rica studying earthquake phenomena.

P. C. STOESS, mining engineer, of Seattle, Washington, was at Denver last week.

CYRUS ROBINSON sailed from New York for Europe, July 13, on professional business.

V. V. CLARK has opened an office at Seattle to engage in mining engineering practice.

EDMUND JUESSEN has established headquarters in the Sheldon building, San Francisco.

OLIVER B. FINN has been examining dredging ground on Burnt river, in eastern Oregon.

STANLEY C. HEROLD, of Tonopah, Nevada, was at the Palace Hotel, San Francisco, last week.

C. K. LEITH has gone to Rio de Janeiro, by way of London. He will return about October 15.

EDGAR D. STONE has changed his address from Box 462, Atlanta, Georgia, to 63 Park Row, New York City.

STANLEY C. SEARS has been appointed general manager for the Mexico Con. M. & S. Co., Parral, Chihuahua, Mexico.

PHILIP N. MOORE will be in central Idaho soon and probably will visit San Francisco before returning to St. Louis.

J. J. WELCH, superintendent for the Mason Valley Mines Co., has returned to Mason, Nevada, after ten weeks' vacation.

SAMUEL S. AAENTZ, general superintendent for the Nevada Douglas Copper Co., and the Nevada Copper Belt railway is at Los Angeles.

ARTHUR K. ADAMS has resumed his position as Mineral Inspector in the General Land Office, making his headquarters at Cheyenne, Wyoming.

DYKE V. KEEDY and CARL F. DIETZ, of the firm of Dietz & Keedy, metallurgical engineers, of Boston, have gone to Virginia to make professional examinations.

CHARLES W. WAIGHT, consulting engineer for the Societa di Pertusola mines in Sardinia, has returned to Washington for the summer to complete some work on the Geological Survey.

FRANK BAIRD, metallurgist at the Penn Chemical Works, Calaveras county, California, has accepted a position with the Pacific Foundry Co., of San Francisco. DONALD SMITH succeeds him as metallurgist at the Penn Chemical Works.

E. B. STURGIS, for a number of years engaged in mining examination work, is now associated with the J. R. Alsing Engineering Co., manufacturers of grinding, crushing, and pulverizing machinery. The new office of this concern is at 90 West street, New York City.

R. B. LAMB, mining engineer, of New York City, has concluded examinations at Argenta and York, Montana, and the Ohio Keating mine at Radersburg, Montana, for the Radersburg Con. M. Co. Mr. Lamb is now at Eldorado, California, making an examination of the Manhattan-California G. M. Co.'s property for the Radersburg Con. He will return to New York the end of July.

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the Mining and Scientific Press.

Handbook of Cost Data. By H. P. Gillette. Second Ed. Pp. 1854, ill., index, flexible leather binding. M. C. Clark Pub. Co. Chicago, 1910. Price $5.

The fact that a second edition of this work is demanded sufficiently indicates its usefulness. In preparing the new volume Mr. Gillette has included so much additional material that the work has been expanded nearly four-fold. The result is that a vast amount of miscellaneous cost data has been included, and while all such material must be intelligently applied in order to be useful, the author has done what he could by classification and selection to safeguard mistakes. The book is one that will be welcomed by all contractors and construction engineers.

Who's Who in Mining and Metallurgy, 1910. Pp. 290. *The Mining Journal*, London, 1910. Price $4.50.

This work includes 147 pages devoted to individual biographies, 123 devoted to a directory of engineering societies, and 15 to a list, with address, of makers of mining supplies. The directory of societies is much the most complete feature of the work. The individual biographies, while concise and useful, are by no means as numerous as the importance of mining justifies. We sincerely hope that patronage may be sufficient to warrant rapid expansion of succeeding editions of the work, since a really comprehensive 'Who's Who' would be vastly useful. However, the present book is much the best directory available, and the publishers deserve great credit for their enterprise in furnishing it to the profession.

Ore Mining Methods. By Walter R. Crane. Pp. 219, ill., index. John Wiley & Sons, New York, 1910. Price $3.

There has long been a need for a book such as this in which the methods of mining ore were described and discussed. General text books of mining cover too wide a range to give the detail so much needed. In the past it has been necessary for each engineer confronted by a new problem to travel and see or to search laboriously through the scattered periodical literature on the subject. This will still be the best way, but with Mr. Crane's book at hand he will have a guide. A wide range of mining methods are described almost entirely from first hand knowledge and the illustrations are fresh and new. We wish that the descriptions had been made somewhat more detailed, and we are sure it would have been helpful had references to special articles been included. The chapters, while brief, are almost always clear and are conveniently summarized. The book will form a welcome addition to the library of every engineer in charge of underground work.

The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

T. N. S., Ameca, Mexico: Serpentine.

F. A. L., Glenns Ferry, Idaho: Calamine.

H. S., Halifax, Nova Scotia: A, granite; B, hornblende schist.

J. H. P., Golconda, Nevada: A, micacous schist too badly decomposed to determine origin; G, silicious limestone.

J. C. S., Danville, Washington: No. 14a, gabbro; No. 17, serpentine; No. 18, hornblende schist; No. 19, gabbro with chalcopyrite; No. 20, magnetite; No. 21, silicified slate.

A. S. C., Ocotlan, Mexico: No. 1, fine grained metamorphosed silicious rock, probably rhyolite; No. 2, dolomitic limestone; No. 3, andesite tuff; No. 4, andesite tuff; No. 5, rhyolite; No. 6, andesite; No. 7, andesite.

Recent Publications

Earthquakes: Their Causes and Effects. By Edmund Otis Hovey. Re-print. Proc. Am. Philos. Soc., Vol. 48, No. 192. Pp. 235-258. Philadelphia, 1909. This is an excellent general summary, with specific accounts of a number of the great shocks, written by the accomplished secretary of the Geological Society of America.

Wet and Dry Differentiation of Igneous Rocks. By A. C. Lane. Tufts College Studies, Vol. III, No. 1. Pp. 39-54. May 1910. This is an interesting comparison between the results obtained by Arthur Day and his associates in the investigations of the melting of rocks, with field observations at Mount Johnson, Quebec.

Transactions of the American Institute of Mining Engineers, Vol. 40. Pp. 946, ill., index. New York, 1910. This volume contains the papers and discussions of 1909, and while they are already familiar through the Bulletin, they are here presented in revised form. The volume marks a useful rather than notable year in the activities of the Institute, and in particular the volume is much better balanced than have been some of the predecessors. The Institute covers mining in its widest sense, and in volume 40 many phases are treated in a significant manner.

The West Virginia Geological Survey has just issued two new publications; a new and revised edition of its Coal, Oil, Gas, and Limestone Map, and a detailed report with accompanying topographic, geologic, and soil maps, covering the counties of Pleasants, Wood, and Ritchie. A full description of these publications and how to secure them is given below:

1. New Edition of the Coal, Oil, Gas, and Limestone Map. This new edition contains a thorough revision of the coal, oil, and gas development, being brought up to date as nearly as possible. The new railway lines constructed since the last edition was published, August 31, 1908, have also been added. The names and post office addresses of all the coal companies operating in West Virginia up to the early part of 1910 are given on the map by counties, and the mines are indicated by appropriate symbols and numbers. The extension of the great Burning Springs Anticlinal southward from the Little Kanawha river through Wirt and Roane counties is correctly indicated on this map for the first time from field studies made by Ray V. Hennen during 1909 and 1910, and its extension northward to the Ohio river, is also given from the detailed studies of G. P. Grimsley during 1908 and 1909. Scale, 7 miles to the inch. Price, enclosed in strong envelope and delivered by mail, 50c. each.

2. New Detailed County Report, on Pleasants, Wood, and Ritchie Counties, with a case of topographic, geologic, and soil maps, assembled from the accurate topographic sheets of the U. S. Geological Survey into single large maps embracing the entire area of the three counties. The text of this Report, containing 352 pages + XIV, gives interesting descriptions of each county, its history, industries, mineral resources, soils, etc., as well as many detailed records of oil and gas borings. The soils of the district have been studied, mapped, and described by the experts of the Bureau of Soils of the U. S. Department of Agriculture. The topographic and geologic maps show all the roads, by-roads, houses, school houses, churches, villages, streams, etc., and also the elevations above tide all over the areas of the three counties. The oil and gas pools developed up to 1909 are also shown by appropriate symbols. Price of volume and case of maps, postage or express prepaid, $1.75.

Teachers and public libraries get a discount of 40% from the prices quoted on this circular, but they pay the delivery charges, either express or postage.

Application should be made to I. C. White, State Geologist, Morgantown, West Virginia. A complete list of publications with special discount rates for combinations will be sent on request.

GOLDFIELD CONSOLIDATED FOR JUNE

The preliminary report for the month of June, by J. R. Finlay, general manager, is now available, and from it the following abstract has been prepared.

TONNAGE PRODUCED

	Wet tons.	Dry tons.	Av. oz. per ton.
Combination	4,936	4,715	1.14
Mohawk	6,927	6,617	1.46
Red Top	3,777	3,608	1.99
Clermont	5,393	5,151	4.23
Total	21,033	20,091	2.19

The gross amounts to be credited to the various mines are as follows:

Combination	$111,085
Mohawk	199,701
Red Top	148,397
Clermont	450,297
Total	$909,480

The performance of the mill was as follows:

Dry tons milled	20,091
Average value per ton	$45.27
Total value	$909,480
Loss in tailing	$41,216
Value realized	$868,264
Percentage extracted	95.47

General:		Amount.	Av. per ton.
Bullion tax and marketing bullion		$19,000	
Administration, etc.		18,000	
		$37,000	$1.84
Mining		80,000	3.98
Transportation		2,800	0.14
Milling:			
Milling and cyaniding	$50,000		
Marketing concentrate residue.	5,000		
		55,000	2.74
Construction and fire loss		65,000	3.23
Cost		$239,800	$11.93
Loss in tailing		41,216	2.05
Total costs and losses		$281,016	$13.98
Profit per ton		$31.29	
Total value of ore		$45.27	
Total profit for month		$628,464	
Percentage of profit		69.10	

The extraction by the mill was unusually good. In this connection it is to be noted that in the tailing-losses there are included this month more than 300 oz. of gold in concentrate residue. This residue has heretofore been shipped to smelters and the entire amount of concentrate included in the saving reported. But this month more than half the concentrate residue was too low grade to cover freight and treatment charges, so that it was piled on the dump and the gold content included with the other tailing.

At the mill the essential parts are completed for running at full capacity, but some further work in the way of changes made necessary by the fire and mere finishing touches will continue for some time. The Columbia Mountain fire protection scheme, the storage battery plant, a new assay office, a new engineering building, new transformer houses, and a new head-frame and ore-bins for the Laguna shaft are designed and under way. All this construction is fire-proof and the intention is either to secure economy in operating or to protect vital parts of the plant from fire. During April, May, and June the constant expenses have been written off more rapidly than the money has actually been expended. All construction now in sight will be completed by October, and for the remaining months of the fiscal year the costs on this account will be comparatively small.

DEVELOPMENT

During the month the total advance was 2861 ft., equal to one foot for every seven tons mined. The work was distributed among the various mines as follows:

	Feet.
Combination	367
Mohawk	914
Clermont	1,212
Red Top	294
Laguna shaft	74
Total	2,861

Ore was taken from main levels as follows:

	Tons.	Av. oz.
Mohawk:		
350-ft. level	111	0.53
450-ft. level	165	0.50
Clermont:		
600-ft. level	565	1.15
750-ft. level	182	0.95
900-ft. level	161	0.37
	1,184	0.86

BUTTE PRODUCTION IN JUNE

For June, the first month under the completed Anaconda merger operations, the Butte mines produced 26,317,200 lb., against 28,363,760 in May. It is not certain that the reduction is the result of a policy of intentional curtailment; officers of the Anaconda company say not. Both the Anaconda and Great Falls smelters are operated to capacity, but they are not able to treat all the ore that has been shipped to them since the Anaconda company took over the Clark copper mines, which yield about 500 tons of ore per day. The reduction about represents the ore that was formerly mined in excess of the capacity of the two smelters, no more ore being shipped to the old Clark smelter. The average daily ore tonnage, the average yield per ton in copper, and the daily production in June were about as follows:

Company.	Daily, tons.	Lb. of copper per ton.	Daily copper output.
Boston & Montana	3,650	70	255,500
Anaconda	4,120	62	255,440
Butte & Boston	530	64	33,920
Washoe	400	62	24,800
Parrot	150	66	9,900
Trenton	390	62	24,180
North Butte	1,050	68	71,400
Butte Coalition	1,400	70	98,000
Butte-Ballaklava	110	180	19,800
Tuolumne	150	110	16,500
East Butte	320	90	28,800
Original	500	70	35,000
Miscellaneous	50	80	4,000
Totals	12,820		877,240

The month's totals were:

Company.	Tons of ore.	Lb. of copper.
Boston & Montana	109,500	7,665,000
Anaconda	123,600	7,663,200
Butte & Boston	15,900	1,017,600
Washoe	12,000	744,000
Parrot	4,500	297,000
Trenton	11,700	725,400
North Butte	31,500	2,142,000
Butte Coalition	42,000	2,940,000
Butte-Ballaklava	3,300	594,000
Tuolumne	4,500	595,000
East Butte	9,600	864,000
Original	15,000	1,050,000
Miscellaneous	1,500	120,000
Totals	384,600	26,317,200

JUNE COPPER PRODUCTION

The figures of the Copper Producers Association for June offer some encouragement. The production and imports of the metal in June amounted to 127,219,188; domestic deliveries, 53,362,196; exports, 65,895,948; total surplus, 168,386,017 lb. The surplus was increased by just 7,960,044 against 18,441,814 lb. during May, a gain on the right side of 10,481,770 lb. of the metal.

Upon these figures L. Vogelstein & Co. comment as follows under date of June 8. "The statistics for the month of June show an increase in stocks of 7,960,044 lb. For the same month the stocks of copper in English and French warehouses decreased 9,788,800, showing a net decrease in the warehouse stocks of copper for the month, of 1,828,756 lb. For the first six months of the year the stocks of copper in European warehouses have decreased 16,755,200; stocks in the hands of American producers have increased 26,619,906; showing a net increase of stocks of copper all over the world of 9,864,706 pounds.

"It has to be borne in mind, however, that during the same period the invisible supplies of copper have materially decreased both here and abroad, partly on account of consumers pursuing a policy of buying from hand to mouth, and partly on account of European dealers having reduced their stocks of copper in various European ports. During the past six months production increased 35,873,941 lb., domestic deliveries 74,662,736 lb., and exports decreased 32,907,909 pounds.

"We are of the opinion that at the present moment and for the last six months, in spite of the enormous production, consumption all over the world has been in excess of production. The maximum of the producing capacity of this country has been reached for the time being, and no further material increase may be looked for during the next six or nine months, while there is every likelihood that consumption, at least in this country, will do better than it has done in the months of May and June. In our opinion the slightest revival of demand is bound to produce higher prices, while enlarging exports at the lower range of values now prevailing, furnish renewed evidence of the willingness of Europe to buy copper when cheap."

American statistics of copper production and consumption in the first six months of 1909 and 1910 may be summarized as below, in pounds of copper.

	Production and imports.	Domestic deliveries.	Exports.	Surplus.
	1910			
January ...	116,547,287	78,158,387	81,691,672	98,463,339

May	118,356,146	61,163,325	70,542,753	169,848,141
June	116,567,493	60,591,116	70,966,457	154,858,061
Totals ...	681,392,609	313,613,157	335,078,657	

THE BULLY HILL property of California made in June the following production: 550,000 lb. of copper, 30,000 oz. of silver, 750 oz. of gold. At present about 50 tons of ore are being shipped daily from the Copper City mine to the First National Co.'s smelter for treatment. This ore averages approximately 6½%, which means that the company is producing, roughly, 180,000 lb. of copper per month. When the smelter shut down on June 30, instead of laying off the men, they were given the opportunity of going to work at the mines which will be kept operating.

BALATA BELTING

Announcement is made that a combination of German and American capital has been brought together for the building of a great Balata belting factory in the United States. Though large quantities of Balata belting are in service for transmission purposes in the United States at the present time, not one foot is manufactured in America. The corporation behind the new enterprise is known as the Victor-Balata & Textile Belting Co. The American interests represented in the new company are Charles E. Aaron and John R. Stein, president and treasurer, respectively, of the New York Leather Belting Co. of New York. The German interests are represented in the new company by William Vollrath, Albert Vollrath, and Edwin Vollrath, of the firm of C. Vollrath & Sohn, of Blankenburgh, Germany. The officers of the new combine are Charles E. Aaron of New York, president; Edwin Vollrath of Blankenburgh, Germany, secretary; and John R. Stein of New York, treasurer. The building of the new plant will entail an expenditure of half a million dollars in buildings and equipment. It will be located at Easton, Pennsylvania. Work on the first two buildings of the new plant will be begun immediately. A 1000-ft. siding is being built by the Lehigh Valley railroad from its main tracks to the factory site. Two buildings to be erected at once include the main factory building, 150 by 100 ft., and an impregnation building, 75 by 60 ft. Both will be constructed of concrete and structural steel to render them absolutely fire-proof. An interesting feature connected with the new plant is that a complete miniature village will be erected on the site to house the workmen of the plant. All the dwellings will be of concrete. A great weaving plant for the weaving of cotton duck will be an added feature as soon as machinery is built. The advent of a plant for the manufacture of Balata belting in the United States brings out many interesting features relative to the manufacture of this type of belting. One of the most interesting is the extreme secrecy which has always guarded the various plants where this belt has been manufactured abroad. The new company expects to begin installing its machinery in September and be in full operation late in October. When the chain of buildings is completed the plant will be the largest textile belting factory in the world.

MULLEN BLACK SAND SEPARATOR

Many attempts have been made to concentrate and save the heavy minerals associated with black sand in placers. This is in line with one of the best efforts of modern industry, to effect closer saving and complete utilization of by-products. C. M. Mullen, now of 1112 East Washington street, Portland, Oregon, but long connected with mining in Colorado, has recently patented a device for removing black sand from the bottom of sluices by means of a movable apron fixed in an extension of the sluice, operated by rack and pinion, and so arranged as to skim from the bottom of the stream a thickness fixed at will. The sand is then diverted to a cross-sluice and further concentrated or shipped direct as needed. The device is simple, cheap, and should be effective in certain situations. It is proposed to operate through a company leasing tailing rights wherever hydraulic mining is under way. Mr. Mullen in this enterprise is associated with I. B. Hammond.

The Penberthy Injector Co. of Dertoit, recently shipped injector number 600,000. That the above company has since 1887 made this number of their automatic injectors, gives some idea of the large horse-power of the boilers which must be in operation at the present time. It has been estimated that 600,000 GG Penberthy injectors would force into a boiler against 90 or 100-lb. pressure, over one-sixth of the amount of water that is constantly going over Niagara Falls; approximately 125,000,000 to 150,000,000 gallons per minute. This when transformed to steam at 70-lb. pressure is sufficient to develop power amounting to approximately 700,748,661 hp., or very near five times the estimated horse-power of the world's steam machinery.

COMMERCIAL PARAGRAPHS

L. S. Pierce, Denver, has moved his office and demonstration plant to 1738 Broadway.

The Samson Mfg. Co., Denver, has moved its office from 1650 Champa street to 1738 Broadway.

Falkenburg & Laucks, of Seattle, have added ore-testing facilities to their chemical laboratory.

The Elspass Engineering & Mining Machinery Co., Denver, has moved its office to 1738 Broadway.

The Redwood Manufacturers Co. announces that Fred H. Flood is now in charge of its cyanide plant equipment department. All cyanide and leaching equipment business will receive his personal attention.

The Mining Exploration Co., with offices at 71 Broadway, New York, advise that they wish for their files, catalogues from manufacturers of machinery used in the mining and reduction of gold and silver ores.

The Redwood Manufacturers Co. advises, among other sales, cyanide plants for the George H. Roth Mining Co., Bolse, Idaho; Inspiration Copper Co., Miami, Arizona; Wasp No. 2 Mining Co., Deadwood, South Dakota.

The Pacific Foundry Co., San Francisco, announces that it has secured the services of Frank Baird as a member of its metallurgical staff. Mr. Baird has until now been metallurgist at the Penn Chemical Works, Calaveras county, California.

The Mine & Smelter Supply Co., New York City, announces that it has taken over the agency for the entire Western territory of the United States of the line of pumps made by the Epping-Carpenter Co., Pittsburg, and the compressors made by the Bury Compressor Co., Erie, Pennsylvania.

Arrangements have been made by the C. W. Hunt Co., New York, builders of coal handling, conveying, and hoisting machinery, by which their business on the Pacific Coast will be handled by the San Francisco Bridge Co., with offices at 865 Monadnock building, San Francisco. The company has just completed a Naval Coaling Station in San Francisco Bay for the Government.

Walter Ives, for the past nine years connected with the staff of *The Engineering and Mining Journal*, and Edward B. Sturgis, a mining engineer of many years' experience, have affiliated themselves with the J. R. Alsing Engineering Co., manufacturers of crushing, grinding, and pulverizing machinery. They have largely increased their engineering force; obtained better manufacturing facilities; and made many other improvements. They are moving to larger and more commodious offices, at 90 West street, New York City. The J. R. Alsing Co. claims to be the pioneer manufacturer of tube-mills in the United States, having been building them for 42 years. Mr. Ives is at present on an extended European trip in the interest of his new firm.

CATALOGUES RECEIVED

Allis-Chalmers Co., Milwaukee, Wis. Bulletin No. 1070. 'Barometric Condensers'. Illustrated. 12 pages. 8 by 10½ inches. Bulletin No. 1071, 'Jet Condensers'. Illustrated. 16 pages. 8 by 10½ inches.

Mulconroy Co., Inc., 723 Arch street, Philadelphia. Catalogue No. 22. Showing metallic hose, rubber hose, and leather-soled rubber boots and shoes. Illustrated. 24 pages. 6 by 9 inches.

Pennsylvania Flexible Metallic Tubing Co., Philadelphia. Booklet, 'Metal Hose'. Illustrated. 22 pages. 3½ by 6 inches. The Western business of this company is handled by the U. S. Flexible Metallic Tubing Co., Los Angeles, San Francisco, Houston, St. Louis, and Seattle.

Harron, Rickard & McCone, San Francisco and Los Angeles. Catalogue No. 2. Fourth Edition. 'Supplies for Mine and Mill, Machine Shop, Power Plants, and Contractors'. This is one of the most complete and best arranged supply catalogues that has come to our attention in some time. A comprehensive index and system of code words is included. The publishers will be glad to send a copy to any one interested. Illustrated. 172 pages. 9 by 12 inches.

TABLE OF CONTENTS

EDITORIAL

PLANS for the work of the Bureau of Mines for the current year have been approved by the Secretary of the Interior and are detailed on another page.

PEAT has never been used in America to any great extent. Both in the United States and in Canada there are great areas covered by peat bogs, that contain much potential power and wealth. The American Peat Society, which will meet at Ottawa, Canada, July 25, 26, and 27 has already done much to stimulate interest in the possibilities of peat utilization.

ANNOUNCEMENT in San Francisco papers of the sale of the Western Fuel Company to British investors proves to have been premature. An option has been given and a sale may result but the matter is still undecided. The Western Fuel Company has been a remarkably successful concern. It was formed by consolidation of a number of independent coal-selling companies at the time that competition by oil had reduced the San Francisco coal business to a no-profit basis. By controlling mines, transportation, and market facilities, the company has succeeded in not only holding its own against the new fuel, but has grown and prospered.

DISCOVERY of high-grade gold ore in a deserted silver mine, made T. F. Walsh wealthy and started the great Camp Bird mine producing its millions. A similar discovery has just been made in the Iowa-Tiger, another San Juan, Colorado, property. In this case the mine had not been abandoned but from its lofty position above Silver lake has been shipping lead-silver ore nearly as steadily as its more famous neighbor. Recently occasional high returns in gold caused a search of the mine, and a high-grade streak of ore was found on the hanging wall. Since it differs greatly from the other ore of the mine it had passed unnoticed. The full value of the find is yet uncertain, but we may at least wish that it prove equal to that in the Camp Bird.

LABOR troubles at Butte are feared by the miners. Since Butte is the last great stronghold of the Western Federation of Miners, that bellicose organization will doubtless use every effort to win in case of trouble. Consolidation of ownership at Butte takes away the power that the men have long had of playing one interest against the other, and the defeats that the Federation has sustained in other districts cut off a large amount of outside support that has previously by being available, like the

modern battleship, prevented war. It is hard to see how the Anaconda company can long avoid curtailment of output and anything that causes the discharge of men is likely to precipitate trouble.

PLATINUM is one of the metals of which there seems no danger of over production. The ratio of supply to demand is measured by price, which now stands at approximately $30 per ounce. In other words platinum is at present much more valuable than gold. A number of rare metals are associated with platinum as it occurs in nature. Among these are palladium, iridium, osmium, rhodium, and others. The known uses for most of these are few and prices are more or less arbitrary. In general, however, they sell, when refined, at prices even higher than that of platinum. Alloys of platinum with them are known as 'hard metal' and sell at an advance price. At the same time, owing to the difficulties in refining and the small amount of business transacted, refiners generally make a deduction when buying platinum ores containing any of these metals. America has not produced large quantities of any of these metals though they are known to be widely distributed and to be found frequently in the black sands of placer workings. The Oroville dredging fields yield a small but steady supply. Ore at the Rambler mine in Wyoming has been known for some years to carry small amounts of platinum but concentrate recently made has been found to contain several ounces to the ton of that metal accompanied by notable amounts of the others. It now seems likely that a really important American supply of these metals has been found.

Southern Gold Mining

The general mining laws have never been applied to lands in the Southern States except Arkansas and, to a limited extent, Louisiana. In the others the lands have been either privately or State owned and when, as in Alabama, public lands were present, they have been treated as entirely agricultural by virtue of special congressional enactments. Gold has been mined in a number of the States, but in the last half century the superior attractions of the West, with the disorganization of industry due to the Civil War, has prevented the normal growth of the industry. One of the most interesting attempts to re-establish gold mining in the South is now being made by the Columbia Mining Company owning a large tract in McDuffie county, Georgia. This company proposes to open the whole area to prospectors. Men may stake out claims 1500 by 600 feet in size, and, in event of discovery being made, will be given free all ore to a depth of 100 feet. Beyond that they may have a lease on the ground with a bond for its purchase if desired. Ore may be treated in the company mill or separately as desired. Work must be done under direction of the resident engineer and, while extra-lateral rights apparently are not to be recognized, there seems to be no limit to the number of claims that may be taken by each man, provided the work be done in good faith. The plan has some of the features of the Western public land law and also resembles the Joplin leasing system. In that it opens large areas to active prospecting and provides for real work on the claims, it is good. How it works will, obviously, depend on the success of the first prospectors in finding ore and the attitude of the company in interpreting the contract. If the rules of interpretation adopted by the courts in cases under the United States mining law be followed, nothing more can be asked.

The recent record of Southern gold mines has not been such as to inspire confidence. The ores are admittedly low grade and in part refractory. The land has been the picnic ground of the process man and the stock of the companies operating there has been the football of the New York curb. Yet gold in large quantity has actually been won in the southern Appalachians and much more undoubtedly exists. It is not a region attractive to poor prospectors working alone, and large companies have generally scored a failure. It remains to be seen whether a combination of the two can not solve the difficulties.

Lake View and Oil Prices

The phenomenal and diabolical production of the Lakeview gusher continues. It has ceased to be a novelty, but its output is so tremendous and its effect on the oil industry so demoralizing that it cannot be forgotten. When the well first came in, it was looked upon with favor by most oil men. It would call the attention of the world to California oil, and show how lavish with her mineral wealth Mother Nature had been to us. The well was expected to flow for a few hours or days, until all eyes had been attracted and would then accommodatingly sand up until its production was needed. The Lakeview had no such intention. Its program has never varied, except in degree, from day to day. It has produced in a steady torrential stream. Its daily output has been more than the total daily production of any other field except Coalinga. It has entirely changed the outlook of the industry. The stupendous production calls for greatly increased storage and transportation facilities. Add to this the uncertainty as to the length of time the gusher will continue, and there is sufficient cause for the present slump in oil.

The present depression will probably continue only until transportation facilities can meet the production. Were the Lakeview to cease flowing within the next fortnight, it is probable that equilibrium would soon be restored, at least temporarily. It is significant that the output of the Lakeview very nearly equals the present overproduction. It must be borne in mind, however, that there will be more large wells in the Midway district, and there is always a chance of another Lakeview upsetting the market. The latest cut in prices to the consumer will doubtless help to extend the consumption in California. There has been no decided lowering of prices to the producer, but no long-term contracts are being drawn by the marketing companies, and the members of the Independent Oil Producers Agency, in their present co-operative arrangement with the Union, are receiving only a little more than

one-half what they got from the Associated last year. It is to be hoped that the present slump will have the effect of calling public attention to the many illegitimate and overcapitalized concerns whose unscrupulous promoters have been preying upon uninformed investors. It is also to be hoped that it will have a tendency to check the recent feverish and wasteful activity of development. Already a curtailment of development can be noted, but there are enough wells even now being drilled in what is probably gusher territory to keep the production above the consumption for some time to come.

The unusually high pressure of gas encountered in all the wells drilled to a sufficient depth in the Buena Vista hills, promises another inducement to great manufacturing industries on the Pacific coast. There is little reason to doubt that pipe-lines will be extended to San Francisco bay as soon as it is demonstrated that a sufficient quantity of gas exists. At present the gas in the wells of the Standard and the Honolulu Consolidated is considered more of a menace than otherwise, and is a great source of trouble in drilling for oil.

Meeting of the Chemists

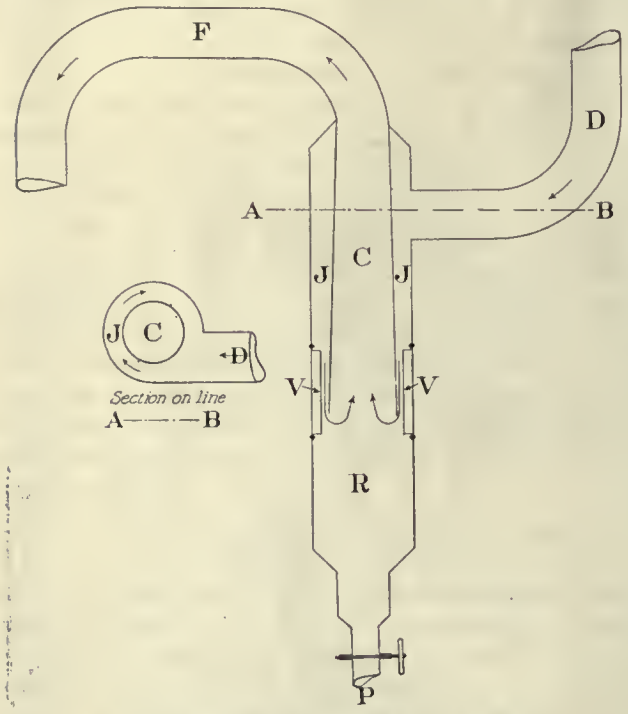
The American Chemical Society, which has just closed a highly successful meeting in San Francisco, is at once one of the most prosperous, as it is useful, of the great scientific societies. With some 5000 members scattered throughout the United States, Canada, and other countries, and including men pursuing all branches of the science, the Society is a great union of both practical and scientific workers. It has become so large that its work is organized in sections by subjects, and its membership in branches arranged geographically. The annual sessions bring together men from all parts of the country and with various points of view. The papers read are sure to be scholarly and the discussions important. At the San Francisco meeting one session of the section of Industrial and Engineering Chemistry was devoted to a symposium on smelter-smoke problems. Papers by Charles Baskerville, W. C. Ebaugh, and F. G. Cottrell were read, followed by a general discussion. The whole will be published in full in one of the journals of the society, for this organization not only meets in sections but also publishes in sections; three distinct journals being supported. Mr. Cottrell's paper attracted the largest amount of attention. He illustrated by lantern slides the various steps taken in the development of the electric precipitation process, and later, at the Selby smelter, where the chemists were guests at luncheon Friday, showed the process in operation on a working scale. So successful has it proved that a much larger installation is now being made to clear the smoke at the Coram plant of the Balaklala Consolidated Copper Company, and thus again the scientific chemist, coming in touch with the practical problems of the mining industry, has given service.

The meeting of the Society calls to mind, at once, both the antiquity of the science and the marvelous developments that, in recent years, have been made by it. The science of chemistry dates back to the commencement of the Christian era and is supposed to have originated in Egypt. The art of metallurgy, which today so blends with chemistry that it is often difficult to find the line of demarcation between the two, is of even older origin; some of its processes being mentioned in the Old Testament. Though the description is clouded, perhaps, by Biblical poesy, there can be little doubt that Jeremiah had in mind the refining of silver by cupellation when he wrote: "The bellows are burned, the lead is consumed of the fire; the founder melteth in vain: for the wicked are not plucked away. Reprobate silver men shall call them, because the Lord hath rejected them." The science soon abandoned the effort to turn base metals into gold, and yet today we seem to be nearer to the transmutation of metals than ever before. It is not, however, the avaricious transmutation of the alchemist, nor is it the work of man, but rather the watching and understanding of A Wonderful Nature doing her own transmutation.

From the work of Ramsay, Rutherford, and Soddy, supported by an army of able experimenters, we learn that uranium slowly but surely transmutes itself into ionium, then into radium, which, in its turn, is degraded into other substances. So it is with thorium and other radioactive substances, and there appears to be every reason to suppose that all the elements are slowly undergoing transmutation, but the change is so infinitely slow that in the paltry length of our lives, in the cases of the more stable metals, we are unable to detect it. Still it is one of the triumphs of modern chemistry that changes which are taking place with such infinite slowness can not only be observed, but actually timed and measured and weighed. The ingenuity of the chemist, who has devised apparatus for doing this, is truly wonderful. It is no ordinary chemistry, with its flasks and beakers, and burned and stained fingers, that accomplishes these minute measurements and weighings. Imagine rather a balance made entirely of fused quartz, the beam of which weighs less than half a gram, and hanging from one end of the beam a fused quartz bulb containing a known quantity of air, while suspended from the other end of the beam the substance to be weighed. Imagine the counterpoising of this balance being made, not by the addition of familiar weights, but by the alteration of the air-pressure within the fused-quartz bulb. Then stretch your imagination once more and think of the movement of the indicating needle—a quartz fibre—being read by the aid of a powerful microscope. For measuring liquids and gases, picture the clinical thermometer, over which the doctor strains his eyes when taking his patient's temperature, and recognize that this is much too coarse an apparatus and that the tube has to be drawn out, to reduce its size, before it is possible to measure the emenation thrown off by the metal radium. Such are some of the instruments the chemist of today is using in his researches in radioactivity and transmutation. What new marvels will be discovered time alone can tell.

Dust Extraction From Smelter Smoke

The problem of precipitation of dust from smelter smoke has engaged the attention of metallurgists for many decades, and it still offers opportunity to trained investigators. The staff of the Copper Queen Consolidated M. Co. at Douglas, Arizona, under the direction of G. B. Lee, the smelter superintendent, has been conducting a series of experiments for the purpose of determining the conditions under which the solid matter in the smoke may be precipitated and recovered. The details of this study will soon be available in a paper to be published in the Bulletin of the American Institute of Mining Engineers. The effect of temperature, expansion of volume, velocity of the gases, and the like, have been carefully inves-



Dust Extraction at Calumet & Arizona Smelter.

tigated, and an enormous amount of data accumulated. The experimental plant in which these observations were conducted consists of a 6-in. pipe running up the side of the stack, and turned by elbows so as to take the gases from the centre, an exhaust being so applied to this pipe as to secure an accurate sample, leading the fume away at the same velocity as that at which it rises in the stack. Chambers provided with means for observation of temperature, pressure, etc., receive the gases below. These lead to an experimental bag-house. The immediate result of the work done at this plant has been a decision to enlarge the existing dust-chamber. At the Copper Queen smelter the dust-chamber depends upon volume rather than length for efficiency, and is not provided with baffle-walls, nor with means to increase friction by extension of the surface-area in contact with the gases. The flue opens directly into a wide high chamber, which becomes narrower by successive steps toward a short flue leading to the stack. Thus the advantage accruing from the chamber is that due to expansion. The chambers are merely being enlarged in their horizontal dimensions.

The amount of dust mechanically carried into the atmosphere through the stack of the Copper Queen smelter is large, and its recovery is entirely an economic measure. The precipitation of the sulphuric anhydride does not enter into the problem, as there is no contest with the farmers at this point. The agriculturists at Douglas seem to be as content to have the smelters in their midst as are the farmers of New Jersey, who abide in peace with their metallurgic neighbors. In fact the situation at Douglas is unique. The diurnal variation in temperature is normally great, and at certain seasons the change is so severe as to prove fatal to agriculture. The smoke from the smelters, however, spreads a gaseous mantle over the valley which opposes the radiation of the heat absorbed by the earth during the day, thus rendering possible the utilization of a considerable area for raising a large variety of crops which formerly could not be grown at all.

The Calumet & Arizona smelter, situated near the Copper Queen, on the outskirts of Douglas, has also taken in hand the problem of recovery of the fine dust which fails to settle in the dust-chambers. It must be said that at neither smelter has the provision for arrest of dust been as elaborate as that at the majority of large smelters, and the temperature of the gases in the stack is relatively high, owing to the short travel from the furnaces and to the small dilution with air. The Calumet & Arizona is just installing an experimental apparatus for dust-recovery, the elements of which are shown in the accompanying sketch in plan and vertical section. The gases are led to the apparatus through the flue D, which connects eccentrically with the settling cylinder R. Within this cylinder, which is 12 ft. diam., is another cylinder set concentrically, expanding from a diameter of 6 ft. at the top to 8 at the bottom. This produces an annular chamber J J. When the gases enter this on one side they are given a rotary motion as they sweep around the inner cylinder R. On passing below the open mouth of the inner cylinder C they come into an expanded area, and thus their velocity will be checked. The reduction of velocity is aided by the opposition of a series of vanes, V V, projecting 1 ft. inward from the shell of the outer cylinder R. The dust that falls will be drawn into bins through the valve P, while the gases will issue through C to the flue F. A similar dust extractor was applied to the gases issuing from an iron blast-furnace in the East, and is said to have given good results. The new appliance will soon be in operation at Douglas, under the direction of James Wood, the smelter superintendent. The plans were drawn by A. J. McDermott, assistant superintendent, and James A. Potter, civil and mechanical engineer to the company.

During the month of June the U. S. Geological Survey reported the classification of 1,244,501 acres of coal land and 1,306,655 acres of non-coal land. The sale price of the coal land was fixed at $80,605,666. The minimum price fixed by law for the same land is $14,300,923.

Mining at Shungnak, Alaska

By Lewis Lloyd

In the year 1898, when the Alaska gold excitement was at its highest, there appeared a luring advertisement at San Francisco of the fabulous finds of the Kobuk river country on the Arctic slope, where gold was found 'as large as hickory nuts' and that the officers of the revenue cutter *Bear* were staking or working natives to take out these hickory nuts of gold. This advertisement brought over 2000 men from their homes in all kinds of crafts to reap the

Sluicing on Dahl Creek.

golden harvest that they supposed awaited them. They camped along the banks of the Kobuk river and its tributaries, disappointed and disgusted, until the spring of 1899, when they left Kotzebue sound. But a few remained, myself included.

The miners at Shungnak have been rather quiet

Home-Made Car, Wheels Bushed With Tomato Cans, at Shungnak Copper Mine.

about what is doing, but it should be remembered that development on mines here is all done with money taken from the mines themselves, that all provisions are brought in, and that all the Eskimo laborers receive $3 to $4 per day and board, in the working season. This speaks well for the mineral resources, and if staying with it is all that is needed, this district will come to the front in the near future. The placers have paid every expense of the few whites and the Eskimos. Dahl creek is the chief source of production. Every season sluicing is resumed on that creek, Riley creek, and the Shungnak river, and many nuggets are taken out, the largest, thus far, valued at $56.63. Placer gold is not the only thing found here. Great copper deposits have been discovered and at present two good copper prospects are being developed. The Ruby Creek copper mine has a steam-hoist and a frame set up, the shaft is down 65 ft. The orebody is 300 ft. wide. The Aurora copper mine has completed a 100-ft. adit which will tap a large body of ore at a depth of 160 ft. Twenty claims are included in the Aurora mountain group on which the ore outcrops for two

Ruby Creek Copper Mine.

miles. The ore is bornite and chalcopyrite, assays showing the bornite to contain 58.41% copper, and $1.72 silver and gold. The chalcopyrite assayed copper 28.44% with a trace of gold and silver, while some ore from the Ruby Creek mine ran, copper 11.71%, gold and silver $1.84. Samples from the Sunny Side

Hoist and Boiler in Tent at Ruby Creek Copper Mine, Shungnak.

group assayed, copper 9.81%, lead 27.73%, gold and silver $2.55; and the Midnight Sun group assayed, copper 5.59%, lead 13.56%, gold and silver $1.24. All these are from surface prospects. Coal also occurs in the district. Following is a list of the minerals that I have determined thus far: asbestos, coal, jade, kaolin, and talc, also gold, galena, pyrite, pyrrhotite, zinkite, tetrahedrite, sphalerite, bornite, chalcopyrite, and copper carbonate, in quartz. Since its discovery ore has been shipped yearly.

Bureau of Mines Plans

The acting director of the Bureau of Mines, George Otis Smith, has announced the following plans for the work of the present season.

The act establishing a Bureau of Mines in the Department of the Interior, approved May 16, 1910, became effective July 1. As originally approved, the law contemplated the transfer of the entire Technologic Branch of the United States Geological Survey, the mine accident investigations, fuel investigations, structural materials investigations, including the entire personnel, property, and equipment, to the Bureau of Mines. The Sundry Civil appropriation act, approved June 25, however, amended the law to such an extent that the structural materials investigations, including the personnel and equipment for these investigations, went to the Bureau of Standards, Department of Commerce and Labor. The Secretary of the Interior has therefore transferred to the Bureau of Mines the investigation of mine accidents and fuels, together with the personnel and equipment of these investigations, and to the Bureau of Standards the structural materials investigations and the employees of the Technologic Branch of the Survey engaged thereon. The fully equipped Testing Station at Pittsburg goes to the Bureau of Mines. The Bureau of Mines therefore includes the mine accidents and fuel investigations for which an appropriation of $410,000 was made by Congress. The total appropriations for the Bureau, including salaries, rent, and expenses of removal amount to $502,200.

The work of the Bureau of Mines for the first year will be a continuation and expansion of the work carried on by the Technologic Branch of the Geological Survey. The law in itself provides for a variety of other problems that properly belong to the Bureau of Mines and which should eventually be undertaken, such as methods of mining and metallurgical processes, but these activities will be deferred for the most part until Congress gives adequate appropriations. The spirit of the debates in Congress both on the Bureau of Mines legislation and on the appropriation items emphasized the desire to regard the mine accidents investigations as urgent, and this will be the feature of the work. In all, $310,000 was appropriated for mine accident investigations. Of this sum, under the general plans approved by the Secretary of the Interior, $120,000 is to be spent on the rescue stations, $36,000 for housing nine stations, $34,000 for equipping eight new stations, and $10,000 for additional equipment for five existing stations. The allotment for the investigation of explosives is $40,000; for electricity in mining, $14,000; appliances for preventing mine accidents, $8000; examination and codification of mining laws, $5000; and other technologic investigations, ore treatment, etc., $10,000. For the analyzing and testing of the coals, lignites, ores, and other mineral fuel substances belonging to or for the use of the United States, $100,000 was appropriated. Of this amount, $35,000 will be spent in the chemical and physical investigation of fuels, $25,000 in the inspection of government fuel purchase, $22,000 in fuel efficiency investigations, $5000 in lignite and peat investigations, and $4000 in briquetting investigations. The mine accident investigations, which have been transferred from the Geological Survey to the Bureau of Mines, were first authorized in the legislative appropriation act of May 22, 1908, carrying for this purpose an appropriation of $150,000. This was followed by a similar appropriation carried in the act for the sundry civil expenses of the government for 1910. A mine experiment station was established in Pittsburg during 1908, at which, since that time, investigations of explosives, coal gas, dust, electricity, and other possible causes of mine explosions have been continually under way. The mining engineering field force of the Geological Survey has already made decided progress in the study of underground mining conditions and methods. Practically all of the coal mines in which mine explosions have occurred during the last two years have been carefully examined, the gases, coke, and dust have been analyzed at the laboratory at Pittsburg and every effort has been made to determine the explosibility of various mixtures of gas and air in the presence of shots of different types of explosives. Considerable progress has also been made in the investigation of explosives used in coal mining and the conditions under which they may be used with least risk. Manufacturers have submitted many explosives for test at the station, and a considerable portion of them passed and have been classified among the permissible explosives. Investigations in connection with the use of mine rescue equipment have proved useful and will be continued. The inspection of fuel purchased by the Government will also be continued.

The publications of the Survey relating to mine and fuel investigations, those prepared by the Technologic Branch, will in the future be distributed by the Bureau of Mines. The publications relating to structural materials will continue to be distributed by the Geological Survey. The last of the bulletins of the Technologic Branch to be published by the Survey will be issued from the Government Printing Office about August 1. This bulletin relates to the Explosibility of Coal Dust and was prepared by G. S. Rice, with chapters by J. C. Frazer, Axel Larsen, Frank Haas, and Carl Scholz. The first of the Bureau of Mines bulletins, the Volatile Matter of Coal, by H. C. Porter and F. K. Ovitz, will be published in the next few months. Then will follow Coal Analyses, by N. W. Lord and J. S. Burrows; Final Data Regarding Steam Tests, by L. P. Breckenridge; North Dakota Lignite as a Boiler Fuel, by D. T. Randall and Henry Kreisinger; Producer-Gas Tests in 1905 to 1907, by R. H. Fernald; The Coke Industry as Related to the Foundry, by Richard Moldenke; Coals for Illuminating Gas, by A. H. White and Perry Barker; and Petroleum for Combustion under Steam Boilers, by I. C. Allen. These publications, when issued, can be obtained by addressing the Director of the Bureau of Mines, Washington, D. C.

Economics of Secondary Enrichment—II

By A. M. Finlayson

(*Continued From Page 75.*)

Copper. Ore deposits of copper, owing to remarkable interchangeability and proneness to alteration of the different sulphides, furnish, by secondary alteration and enrichment, the most striking examples among the metals of the economic significance of these processes. The great importance of secondary copper ores is widely recognized. Of the oxidized ores, azurite was mined extensively at Bisbee and Clifton, chalcanthite at Copiapo (Chile), and at Reno (Bluestone mine), in Nevada. Chrysocolla was an important ore in Arizona and Texas, and malachite in the Urals. Of the sulphides, chalcocite has supplied most of the copper at Butte, at Rio Tinto, and in Nevada and Arizona. Secondary chalcocite ore has been estimated to supply most of the United States copper output at the present day. Covellite was abundant in the Gray Rock mine, at Butte, secondary enargite in Colorado and Chile, bornite in Chile and at Mount Lyell. Secondary enrichment pulled Mount Lyell through a critical epoch in its history and transformed the upper portion of Mount Morgan into a gold mine. The rich secondary ores of the Anglesea and Wicklow pyrite deposits once enabled the British mines to dominate the copper market of the world, and with the exhaustion of these rich ores, most of the old British copper mines ceased to produce. Recent work by American geologists on the relations of the copper ores has shattered some illusions and prepared the way for a clear understanding of the principles of alteration.[10]

The occurrence of primary enargite at Butte is a case in point. The existence of lean cupriferous pyrite, in which the copper is primarily combined with the pyrite, has been suggested by some writers, but James F. Simpson has shown that at Butte the copper occurs as definite minerals (enargite and chalcopyrite) enclosed in the pyrite. Similarly, at Rio Tinto, lean ore examined microscopically by myself shows in every case minute grains of chalcopyrite, with or without alteration products, embedded in the pyrite.

The respective alteration zones of copper deposits are generally fairly well marked. The normal order is leached and impoverished gossan, zone of oxidized ores, zone of enriched sulphides, and finally zone of unaltered and lean sulphides. A dense limonite gossan commonly indicates pyrite beneath, and in such cases, owing to the strong reducing influence of the predominant pyrite, oxidized ores of copper may not be formed. Limonite is the characteristic mineral of the gossan, but in arid regions, hematite or specular iron ore may form. The zone of enriched sulphides is nearly always well developed wherever alteration has taken place. As a rule, chalcocite predominates in silicate rocks and porphyry, and in deposits of pyritic ore, as at Butte and Rio Tinto, while oxidized ores, notably the carbonates, are chiefly developed in limestone and porous sandstone. Darsie C. Bard[11] has pointed out that while copper carbonates are often abundant in a carbonate gangue, there may be no enriched sulphide ore beneath, owing to the relative insolubility of the carbonate ore, which collects above the ground-water level and hinders the further transport of the copper. In some respects, oxidized ores and secondary sulphide ores of copper thus mutually exclude each other in their occurrence.

The Spanish mines furnish an excellent type of chalcocite enrichment in dense pyritic ores. The climate is sub-tropical and the mean annual rainfall varies from 25 to 28 inches per annum. The gossan varies in depth from 45 to 90 ft., and its depth is at times an index to the depth of enrichment below. Oxidized ores are absent, and the enrichment consists chiefly in the alteration of the minute grains of chalcopyrite to chalcocite, with continual aggregation of the latter mineral. There is also, however, a good deal of secondary chalcopyrite deposited on the primary mineral. The ore at the top of the sulphide zone carries from 4 to 8% copper, and gradually passes down into lean pyritic ore, assaying 1% or less. The depth at which the unaltered ore is reached varies, in different parts of the district, from 200 to 1500 ft. below the outcrop. This enrichment has been the chief factor in the development of a big mining industry. All the copper produced in past ages was from enriched ore, and the bulk of the Rio Tinto copper production today is obtained from enriched ore.

At Mount Lyell, secondary sulphide ore, often highly argentiferous, has proved similarly profitable. Much of the ore mined today includes siliceous secondary bornite and chalcocite around the borders of the main orebody. It carries 5% copper, as against 2.35% or less, in the unaltered ore. One mass of rich sulphide ore, including much fahlerz and bornite gave 20% copper and 2000 oz. silver per ton, an output of 850 tons realizing £105,000.

The Katanga deposit is an example of extremely rich oxidized ore, forming an impregnation of porous sandstone, and extending to considerable depth. Deposits of this type lend themselves readily to wholesale alteration and enrichment, owing to their porous and stratiform character, which greatly promotes the circulation of underground waters.

In Canada and Alaska, the copper deposits, like those of other ores in these areas, have been subjected to a vigorous glaciation and erosion that has shorn off all the altered ore, and products of enrichment have consequently played no part in the economic development of the mines. The Lake Superior is another of the few great copper regions where superficial alteration has not been of any significance.

In the Appalachian watershed of the United States, most of the copper mines have depended on secondary sulphides, the primary ore being generally too lean. Thus in the Blue Ridge region of Virginia, the profitable ore was shallow and consisted of bunches of chalcocite (smut ore) aggregated from very lean ore disseminated in basalt.

The remarkable chalcocite enrichment at Butte has

[10] J. F. Kemp, *Economic Geology*, Vol. I, 1905, p. 11.

[11] *Economic Geology*, Vol. V, 1910, p. 59.

been determined by extensive fissuring and re-opening of the veins, which has lowered the water-zone to great depths. The miners long ago embodied the practical aspect of this effect in their dictum: "A dry and tight vein is barren; a wet and crushed one is rich." The oxidized zone has an average depth of 50 ft. and a maximum of 400 ft. Oxidized copper ore was generally conspicuous by its absence, except in the Bullwhacker mine, where rich bodies of chrysocolla were worked. The chalcocite ore, which has made the district famous, is succeeded in depth by the uncommon primary ore, enargite. Secondary covellite was abundant in the Gray Rock mine, Reno. H. Sales[12] has emphasized an important point, namely, that the lower level of the oxidized zone is practically independent of the topography, and often forms a horizontal line across ridges and valleys alike. The depth of the water-tables and of oxidation has been determined almost entirely by the character of the country-rock and by the distribution of fissures.

In Utah, Bingham commenced with lead mining, working cerussite ore in limestone. Beneath this, secondary gold ore was extracted for a while, and finally the rich chalcocite ore in porphyry was exclusively worked. It is succeeded by a lean pyritic ore. The country-rock has here been an important factor. Thus lead carbonate ore predominates in the limestone, and chalcocite in the porphyry, oxidation being naturally much deeper in the former rock. At Ely, in Nevada, the oxidized zone, 100 to 150 ft. deep, is generally leached and barren, although rich carbonate ore was mined at Copper Flat. Owing to the recent change from a humid to an arid climate in this region, the ground-water level is depressed into the sulphide zone, being 335 ft. deep. Secondary chalcocite ores are the main asset of the district, and only small bodies of primary ore (chalcopyrite associated with garnet) have as yet been developed.

Similar conditions prevail in Arizona. At Clifton and Morenci, the oxidized zone, from 50 to 200 ft. deep, is succeeded by the chalcocite-pyrite zone, which extends to a depth of 400 ft. or more. The lean pyritic ore beneath is not generally profitable. In the Copper Queen and Globe mines, at Bisbee, oxidized ore has played a leading part, the 'cave ores' of the Copper Queen, consisting of rich copper carbonate in limestone, being formerly famous. In the Globe district nearly all the valuable ore is oxidized. Bisbee shows a notable dependence of sulphide enrichment on fractures. The more massive and compact ore is often lean.[13]

In the Mexican copper districts, climate has been probably the chief factor in determining the extent of alteration. In Chihuahua, the Jimenez mine has been worked almost entirely on secondary carbonates and oxides, while at Las Vigas, malachite is abundant, passing to chalcocite at depths of 50 to 100 ft. The ore here is an impregnation of sandstone, the primary mineral being chalcopyrite. The Cananea mines depend chiefly on secondary chalcocite. Most of this district is elevated and has a comparatively high rainfall. The Los Pilares mine, also in Sonora, has a gossan of specular hematite which extends to a depth of 100 ft. Beneath this are secondary bornite and chalcocite, on which the mine has been chiefly worked, and which gave way to lean primary sulphides beneath the 500-ft. level. The enrichment here has been largely determined by later fracturing which gave access to surface waters.[14]

At Sonora, where the average rainfall is only 11 inches per annum, rich silicate ores occur to depths of from 200 to 400 ft., and are succeeded by a shallow zone of sulphide enrichment, and finally by primary ore. The shallowness of the alteration zones here has been attributed to the low rainfall, and the richness to the absence of erosion.[15] It is thus conceivable that a high rainfall and more vigorous erosion would have formed a leached gossan and driven the bulk of the secondary ore, as at Rio Tinto, down into the sulphide zone beneath the ground-water level.

The Chilean mines owe most of their prosperity to rich secondary ores developed in regions of low rainfall and slow erosion. In the desert areas, oxidation may reach a depth of 1000 ft. locally, and rich masses of chalcocite and oxidized ores are frequent. At Cerro de Pasco, which is situated on the Andean plateau of Peru, 14,000 ft. above sea-level, the oxidized zone, to a depth of 300 ft., carried exceedingly rich silver ore. Famatina (Argentine) is in a mountainous and dry region, where erosion is slow and the water-table deep. The gossan was leached of copper, but carried gold and silver. A zone of oxidized copper ore succeeded, carrying up to 15% copper, with 66 oz. silver, and 1 oz. gold per ton, while most of the primary sulphide ore carries only 3% copper.

FACTORS THAT DETERMINE SECONDARY ENRICHMENT

The chief factors that influence secondary alterations are the metal or ore, the gangue, the country-rock, the fissures, climate, topography, and the geological age and history of the deposit.

It has been seen that certain ores are not influenced by enrichment in place, unless residual concentration take place with leaching of the gossan. Under this head come tin, tungsten, platinum, chromium, and molybdenum. Further, iron ores in the state of massive specularite or magnetite, are not much affected by superficial alteration, especially when, as is usually the case, they are enclosed in highly resisting rocks. Iron carbonate in limestone is prone to alteration, and is seldom of value without it, and the same applies to manganese ore as carbonate or silicate. In the last case, oxidation is liable to extend further with the carbonate, but at the same time, the manganese oxide formed above is often cellular and less compact than that formed from silicate ore, owing to the solution and removal of some of the manganese as bicarbonate. Such criteria may be used, with due reserve, in estimating the depth and composition of the primary ore.

The gangue is often an important factor. In the

case of lead and zinc, cerussite and calamine naturally develop in a carbonate gangue or country-rock. With copper ore, chalcocite tends to follow a silicious or argillacious gangue, while oxidized ores, notably malachite, favor limestone or porous sandstone. In cases where oxidized ore is abundant in a carbonate gangue, sulphide enrichment beneath is often poorly developed, unless, as at Bingham, the country-rock is different. The prevalent dense quartz matrix of gold veins does not favor extensive alteration, and gold ore with a calcite or quartz-calcite gangue is much more liable to enrichment. In this connection, the occurrence of platey quartz pseudomorphous after calcite in the superficial parts of gold veins suggests the possibility of secondary enrichment.

The physical and chemical character of the country-rock is similar in its influence to the gangue, as seen in the case of deposits in limestone. Deposits in highly indurated or metamorphosed rocks, as in the Kolar and Witwatersand districts, and many magnetite deposits, are not liable to be greatly altered. On the other hand, deposits in thermally altered igneous rocks, such as the Tertiary andesite, lend themselves readily to the action of underground waters.

The effect of subsequent faults and fissures, instanced at the Thames, Butte, and Bisbee, is obvious, and indicates the advantage of a detailed examination of geological structure. They are most marked in districts of Tertiary volcanic action, where subcrustal disturbance has continued after ore deposition. The association of bonanzas with secondary fractures, as at the Thames and in the Smuggler and Mollie Gibson mines of Aspen, points to the importance, in such districts, of carefully mapping faults and fractures as development proceeds. At Butte, the presence of fissures and the character of the country-rock has completely nullified the influence of topography on the level of ground-water.

Climate involves two variables, temperature and rainfall. A cold climate is less favorable to disintegration and secondary alteration than a warm climate, and an equable climate is less favorable than one with great seasonal and diurnal range. Thus it is that secondary alteration becomes more important as we approach the equator. Sunny mountain slopes are, for the same reason, more favorable to rich ore near the surface than the cold slopes. The higher the rainfall the more active is the circulation of underground water, which promotes enrichment, while the same amount of rainfall is more effective in a warm than in a cold climate. A low rainfall, on the other hand, gives a deep ground-water level, and extensive oxidation, though in districts of low rainfall the ground-water level is liable to extend below the base of the oxidized zone. The depth of ground-water therefore is not an indication of the depth of oxidation. The effect of rainfall is greatly dependent on the topography, since a heavy precipitation in mountainous districts leads to rapid erosion, which follows close on the heels of secondary alteration, and the primary ore is then very near the surface. The same is the case in recently glaciated areas. Again, rainfall is influenced by three factors: run-off, evaporation, and absorption. The first two are lost, the run-off in mountainous regions and the evaporated moisture in arid regions, while all three factors in turn are influenced by the geological structure and the character of the rocks. In arid regions, where evaporation is intense, a gossan of hematite may take the place of limonite, and owing to the abundance of salt in the ground-water and in the atmosphere, haloid ores of silver are liable to be found. The great future before gold and copper mining in tropical and semi-tropical countries demands a careful study of climate in its relation to secondary enrichment. We know the difference to man between a low-lying, humid, and malarial district, and an elevated, dry, and healthy one, often within a day's march of each other; but we are still groping painfully after a knowledge of the effect of these conditions on the mineral deposits that await exploitation in such contrasted regions.

The value of topography lies in the clue that it gives to the extent of activity of erosion processes. Topography and surface geology are essentially a reflection of climatic conditions, past and present. Other things being equal, topography influences the ground-water level and the depth of oxidation. Where the relief is bold and erosion vigorous, superficial alteration is seldom extensive. Where the relief is subdued and denudation is slow, we may find either the worn-down roots of lodes as in Otago, New Zealand, or, in some cases, considerable enrichment as in the south of Spain. In a worn-down mountain region, some enrichment may be looked for, but the persistence of the ore in depth depends altogether on how far the lodes have been denuded since erosion exposed them, and that is a problem not yet solved.

The geological age of an ore deposit is an important factor in some cases. The older deposits are in general enclosed in more resistant rocks, and having been exposed at the surface by prolonged denudation, they are commonly of deep-seated origin and composed of refractory ore less liable to superficial alteration. Further, such deposits have commonly a massive, unfissured structure, and are seldom situated in belts of recent disturbance, so that fractures and faults are not liable to affect them. In general, then, the older deposits are less liable to alteration than the younger.

The various factors that determine the extent of secondary alteration are intimately involved one with another, and the proper weight to be given to each can only be determined by a study of local circumstances. Only by such means can a just appreciation be gained of the possible effects of secondary alteration in any given case. At any rate, it should be the aim of applied geology to reduce to a minimum the element of trial and error which has hitherto bulked so largely in the prospecting, valuation, and development of mines.

Rainfall is an important factor in determining the mineral content of stream water. The average for surface waters in regions commonly called semi-arid is about four times that of the surface waters of humid regions.

The Black Hills of South Dakota—I

By William H. Storms

The existence of gold in the Black Hills of South Dakota was known many years prior to the great stampede of 1876. Lieut. G. K. Warren, in his report to the Government of his exploration of the Black Hills region, made in 1857, refers to the occurrence of gold in those mountains, and again, in 1859-60, Capt. W. F. Reynolds, in a report to Washington, speaks not only of gold, in the Black Hills, but also of silver, iron, coal, and copper. Gen. George A. Custer, in 1874, also reported the general occurrence of gold in the Black Hills.

The publication of the reports of these various military and scientific observers gave the occurrence of gold in the Black Hills widespread notoriety, but undoubtedly it was the return to the Hills of a number of General Custer's prospectors in the winter of 1874-75, immediately following the Custer expedition, that resulted in starting the famous stampede of 1876. About 25 of the members of Custer's party returned to the Hills at that time. As the country was within the Sioux reservation, the Government was compelled to take cognizance of this invasion by the gold seekers, and a military company was sent to the Hills from Fort Laramie, Wyoming, to round-up the intruders and take them out, which was done. Notwithstanding all the efforts of the Government to keep the gold diggers off the reservation, prospectors continually dodged the soldiers, and hurried into the forbidden land. The Sioux were hostile, and consequently the prospectors, between the soldiers and the Indians, had a hard time. It is related that one party of eight or ten men went in with a four-horse wagon and outfit. One evening they made camp on French creek. Indications were excellent for a storm, but some of the men struck out up the creek to prospect. A mile or two above their camp they discovered, much to their surprise, a camp of soldiers, but fortunately they were not observed by the latter. The prospectors hastily returned to their own camp and gave the alarm. As quickly as possible they broke camp and drove down stream to a place where the slopes were steep and rocky. Here they hid the greater part of their outfit, took the wagon apart, and by great effort moved it up the steep slope over the rocks where it would make no trail. The horses were led far enough away from the creek so that their neighing might not be heard by the soldiers, should any chance to pass that way. At nightfall it began to snow, and by morning there were two or three inches of snow on the ground, completely hiding the trail made in the canyon the day previous. They kept watch of the soldiers, however, and were much gratified, in the morning to see them break camp and soon thereafter ride quietly down the canyon past the hiding place of the prospectors, without the slightest suspicion that anyone was within miles of them. The danger being over, the miners quickly got their outfit in shape again and were soon digging for gold, their digging tools and rifles being side by side in the holes with them. When men were arrested a second or third time by the soldiers and recognized, all their belongings were confiscated and usually burned, and the unfortunate was escorted with others, to Fort Laramie, or to some more distant military post where they were liberated and warned once more not to return to the reservation.

So insistent were the people of the Western States that the Government purchase the Black Hills from the Indians and throw the coveted land open to settlement, that it was finally decided to send another expedition into the Black Hills region for the purpose of making a more thorough investigation of its mineral resources than had yet been made, as there were many who stoutly maintained that gold did not exist in the Black Hills in paying quantities. This expedition was in charge of Walter P. Jenney, and Henry Newton was appointed his assistant. The party proceeded from Cheyenne, Wyoming, to Fort Laramie, where it was joined by a military escort, and later many prospectors in the Hills materially aided in the exploration of the new country. This expedition, by its labors during the summer and early fall of 1875, established beyond all doubt the existence of gold in the beds of many streams of the Black Hills, though little quartz was found that would yield more than a trace of gold, even by assay.

The Government at once commenced negotiations with the Sioux for the session of that portion of their reservation comprising the Black Hills region, finally purchasing it from them, and early in 1876 the famous stampede commenced. Soon there were upward of 40,000 people within the region embraced by the two forks of the Cheyenne river—the Belle Fourche and the South Fork of the Cheyenne. Among the first discoveries of gold in the Black Hills region was that made by a half-breed named Toussaint Kenseler. He had been convicted of murder and was in prison awaiting the execution of the death sentence when he escaped and was not heard of again for a long time. One day he appeared at one of the Indian agencies, probably that at Pine Ridge, and exhibited several quills filled with small particles of gold which he said he had washed from gravel in the foothills of the Black Hills. From his description and a map which he made before his death, it was concluded that the place described by him was near what is now known as Lame Johnny creek, and about ten miles up the creek from the South Cheyenne river, near where the railroad now crosses that stream. In this vicinity are extensive beds of gravel and conglomerate. The material of which the gravel is composed is the hard metamorphosed schist, granite, and other rocks of the Hills, and vein quartz—in fact, the gold-bearing rocks of the mountains, so it is not strange that the gravel is also gold bearing. The conglomerate is not local, but is the stratum that marks the boundary between the Cretaceous and the Tertiary. It is composed of the same materials as the superficial gravel, and like it, is auriferous. This region has received no attention for many years, the richer gulches and bars of the streams within the Hills attracting the early-day miners, while in these later years the existence of

Cambrian Quartzite Lying on Upturned Algonkian Schist, Deadwood, South Dakota.
From Darton, U. S. Geol. Survey

gold in the foothill region seems to have been overlooked or altogether forgotten. It may be that careful prospecting will discover, even at this late day, that the gravels of the foothills are well worth more than a passing glance.

It may seem strange to some that the members of the Jenney-Newton expedition did not find richer placers, and more evidence of mineral than they did. The only reason I can assign for this is that the greater part of their work was done in the southern and central portion of the Hills where the valleys are wider and travel was comparatively easy. The northern Hills, in which are situated the great Homestake mine and the so-called telluride ores, are for most part exceedingly rugged, and at that time must have been a most difficult region to travel through with the wagons and other paraphernalia of a military expedition. Deadwood gulch, the richest of them all, is a narrow canyon, and was a dense thicket of pine and spruce timber, with hundreds of fallen trees, deep washouts, and many other obstructions to the progress of the traveler. It is improbable that any prospector of the Jenney expedition visited that gulch at all, or the discovery that it was gold bearing would surely have been made and followed up with far better results than were obtained in any of the streams of the southern Hills.

The geology of the Black Hills is, for the most part, quite simple. In pre-Cambrian time a great area of schists, slates, quartzites, and other metamorphic rocks of Algonkian age was surrounded by the sea. These ancient crystalline rocks were tilted at a high angle almost uniformly to the northeast, with a strike northwest-southeast. The schists extended over an immense area, for wherever the erosion of the country extends below the Cambrian, schists of this character are exposed over a vast province, extending from the Rocky Mountain region eastward. In the region of the Black Hills the island slowly sank and as the waves encroached upon the land the detritus from the higher country was carried seaward by the streams, finding lodgment in the estuaries and along the shore, forming barrier reefs, spits, and benches of shingle, while in some places the waves cut terraces, processes such as are in progress today under similar conditions. The schists in this region are the metamorphosed sandstones and clay-shales which resulted from the degradation of a still older terrane, perhaps the Archean. They are exposed across the Hills for a distance of no less than 35 miles, but these upturned and altered sedimentary beds do not represent a continuous deposition of sediments during Algonkian time, for in many places in the Hills are found undoubted evidence of folding. On Rapid creek, near Silver City, can be seen one instance, where in a high bluff of blocky slate, the broad lines of sedimentation sweep like a rainbow across the face of the precipice, while the pronounced slaty cleavage is almost vertical. The schists contained many quartz veins—as many, in all probability, as today, and in certain belts these veins and zones of the schist were gold bearing. It is known positively that such was the fact, for in several localities the ancient gravel, now firmly cemented into a dense hard silicious or ferruginous conglomerate, yields gold. The most noted of these occurrences are those in the vicinity of Central City and Terraville, along Deadwood, Blacktail, and Bobtail gulches and their tributaries, and another locality, near the village of Rockerville, about twelve miles southwest of Rapid City. There are many miles of this conglomerate found around the rim of the Hills, but it is not all gold bearing, at least not in sufficient amount to be mined with profit. On upper Boxelder creek, near Custer peak, on Hat mountain, near the confluence of the south fork of Castle creek with the main stream, and at some less noted localities, the conglomerate is copper bearing—the native metal being present at Hat mountain. The copper in these cases was, no doubt, derived from the copper-bearing schists that underlie them. In some places the gravel is but lightly cemented. Three miles above Deerfield, on upper Castle creek, the bed of gravel is 30 ft. thick, uncemented, and contains no copper and as far as known but little gold.

In the deeper waters of the Cambrian sea the sediment deposited was sand, forming by metamorphism a hard dense quartzite, due to the infiltration of a large amount of secondary silica. Pebbles in both the conglomerate and quartzite seldom or never free themselves from the matrix when broken, the line of fracture passing through rather than around the larger fragment. As the land sunk, the sediments continued to accumulate on the floor of the sea. The detritus alternated between coarse and fine sand nearer the shore, and silt in deeper waters. Often these sediments were accompanied by calcareous material, for calcareous shales and sandstones are abundant in these Cambrian rocks, and it is chiefly due to this calcareous material that the Cambrian strata in Tertiary time, became the depository for large amounts of gold-bearing ores. Generally the sands were gray, often deep red, and occasionally white. Many of the sandstone strata are green, a result of the occurrence of a vast amount of the iron silicate, glauconite.

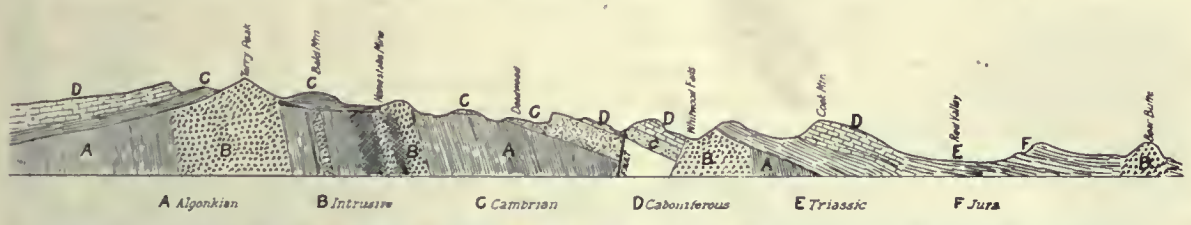
After the close of the Cambrian, the Ordovician, is represented by about 80 ft. of buff limestone above which lies the Carboniferous, the Devonian being, as far as known, entirely absent in the Black Hills. All of the sandstones and shales of the Cambrian contain traces of gold which is probably of mechanical origin, running in some places as high as $2 per ton. The ore deposits previously mentioned as occurring in the Cambrian should not be confused with those just referred to, the latter being contemporaneous deposits, whereas the richer ore deposits are associated with intrusive rocks and are of secondary origin.

Following the Carboniferous came the deposition of the Triassic and Jurassic sediments, and after them the Cretaceous. At the close of the latter, the Black Hills region, which had been slowly sinking during all these ages, was now uplifted, and the entire series of sediments which had encroached far upon the Algonkian island, as it sank, were at this time lifted from their horizontal position, forming a great dome-like anticlinal mass, the strata of which

dipped away from the central portion of the uplift in every direction toward the great plains, in which the Black Hills now rise like an island in a sea. Erosion immediately began, and it was at this period that the gold-bearing conglomerate in the foothills was formed at the base of the Tertiary. The Tertiary was deposited in a fresh water lake and the sediments must eventually have reached a great thickness, extending far up into the Hills, and may possibly have covered them completely. As to this there can never be any positive knowledge, but remnants of Tertiary are now found high up in the mountains, one notable occurrence being that at the southern end of the town of Lead, near the divide between Poorman gulch and Gold Run.

On the surface of these gently undulating beds of the Tertiary, streams began to cut their channels, as the entire region once more was slowly lifted. As the uplift proceeded these channels cut their way ever deeper into the soft strata, the entire surface of which was being itself degraded by those never ceasing elements of destruction—heat and cold, rain and wind. The direction of the streams having been thus determined, they continued in those channels, cutting down into the underlying rocks, in time reaching even the Algonkian schists—the basement rocks of the entire region. While these canyons were being cut out by the streams a vast mass of the older formations—Cretaceous to the base of the Cambrian, was also being removed from the great dome, the Algonkian finally being exposed over a broad elliptical area, and an immense amount of those hard crystalline rocks carried away.

The peculiar drainage of the Black Hills can only be explained by the above hypothesis, for in no other manner could these streams have cut directly through great mountains of hard rock which lay in their course. Ordinarily, a stream, meeting an obstruction, will flow around it, but some of these Black Hills streams are seen to cut through, not around these mountain masses which now look as though they must have obstructed their way, but it must be remembered that the stream courses were determined when they were first formed on the surface of the Tertiary lake bed and when the older rocks through which the streams now run were buried thousands of feet beneath the surface of those Tertiary streams. The Belle Fourche and South Fork of the Cheyenne river and some of their tributaries form the most noticeable examples of superimposed drainage. The erosion of this domal uplift has resulted in the formation of a series of concentric escarpments which encircle and face the Algonkian area of the central portion, each formation, in turn, dipping beneath a younger one. Certain of these formations, in places, are found forming the surface over considerable areas. Such, for instance, are the Lower Cambrian quartzite, which lies at or near the surface over several square miles southeast of Deadwood, from the head of Spruce gulch toward Perry; the massive gray limestone (Pahasapa), which forms the surface over many miles in the western portion of the Hills, and the 'purple limestone' (Minnekahta), which is conspicuous in the foothills, forming precipitous walls, where cut by streams. Over great areas it lies at the surface, and presents the appearance of a rude tessellated pavement.



Geologic Cross-Section Passing Through the Black Hills in a Northeast-Southwest Direction Near Deadwood.

LAND SURVEYS IN ALASKA

In addition to its other work in Alaska the United States Geological Survey will during the present fiscal year make public-land surveys under plans approved by the Commissioner of the General Land Office. An appropriation for this work was made at the last session of Congress in an act which authorizes the Secretary of the Interior to make the surveys by means of the Department's own employees instead of by contract with other surveyors, as heretofore. It is believed that under the new system the work will be greatly accelerated.

The appropriation will be used for subdividing the agricultural lands of Alaska so that they may be taken up as homesteads. The work to be done this season will cover the arable lands around Fairbanks, where many homesteads have already been taken up. A standard parallel and prime meridian will be established and, if time is available, some township lines will be run. The sectional lines will be run next season.

These surveys will be made under the general direction of Alfred H. Brooks, in charge of the division of Alaskan mineral resources of the Geological Survey. R. H. Sargent will have direct charge of the field operations. He will be assisted by C. L. Nelson, W. N. Vance, and S. G. Lunde. Mr. Sargent's party, which sailed from Seattle for Skagway on July 5, includes five or six other assistants, and additional men will be employed at Fairbanks, where horses and supplies will be purchased. The work will be carried on by three parties, each including six to twelve men and six horses. After organizing the work at Fairbanks, Mr. Sargent will go by trail to Valdez. He will make preliminary examinations in the Copper River valley for the purpose of preparing comprehensive plans for land surveys in that region. Mr. Brooks will leave Washington about July 20 for Knik and Cook Inlet, where he will make investigations on which to base land surveys in that district. Later he will visit the Fairbanks parties.

Hand Drilling in Alluvium

By Ernest K. Hall

*In drilling dredging ground not deeper than 40 ft., it is nearly always possible to do the work with hand tools. Quite as accurate results may thus be obtained as by the use of a power plant. The superintendent can quite easily and efficiently attend to three or four sets of these tools and crews, and low first cost and great mobility also favor the hand drill. Boring for an accurate sample is always a delicate matter, and calls for constant watchfulness and resource, though this has often not been fully realized. Many sample holes have been put down without casing, or if casing was used its function was merely to prevent the sides of the hole falling in from above the tool.

A derrick of three light round sticks, giving 17 to 18 ft. head room is set up over the station, and a windlass set across two of the legs for raising and lowering the rods and tools. Suitable windlass rope is $^{5}/_{16}$ in. flexible plough steel. In raising the casing, after a hole is finished, the dead weight of the pipes is a small matter compared with the friction to be overcome, especially where stiff clay has been traversed for a few feet, or where the casing has become jammed among broken boulders. It is handy to have always hanging from the derrick head a 1.5-ton chain hoist. In pulling the casing, give it a turn or two just before pulling with the hoist. If this is insufficient, two sapling poles, like those used for turning the pipe, may be attached to the casing near the ground, by close link chain, and opposite one another. These then may be used as levers.

It is important that casing, rods, and tools be of some standard length. Thus all tools may be 3 ft. in the clear, casing 5 and 10 ft.; rods the same. If this precaution be observed, it is known at once what progress each hole has attained, and how much the bottom of the casing is below the tool. For joints between the casing lengths I prefer the bayonet coupling to a screw thread. It may be thought that this joint is insecure, but so long as the pipes are turned in one direction only, this is not so. I have never found trouble from this cause, even with work manned by ignorant coolie labor. On the other hand, much time and annoyance is saved by its adoption in preference to the screw point. The bottom pipe is shod with a steel cutting shoe, toothed all around its circumference. The shoe's inner diameter should not differ from that of the pipes, which will be anything from 3.5 to 4.5 inches.

When the table is set on the top pipe, and it has on it the weight of two men, a third operator will generally, by turning the pipe line with a pole lever attached by chain, be able to sink the casing a foot or more at a time depending upon the kind of ground being traversed. If this method is not effective the casing must be driven by means of a hardwood block weighing about two hundred pounds, and provided with four arms of 1-in. round iron for lifting. The core of ground is cut and removed by whatever tools are appropriate, to a depth of from six to ten inches above the bottom of the casing. Since the accuracy of the whole operation depends very greatly on the care used in not letting the tool penetrate below the casing, it is advisable always to leave as much as possible of the core near the bottom of the casing untouched, until this is lowered another stage. When a boulder stops the shoe it is necessary to break and remove it with the tools, but in this case, as a general rule, small material will not flow in from the sides to vitiate the sample. Still, it sometimes will do so, especially if the boulder is so steeply inclined, or irregular in shape, as not to close the bottom of the pipe, while the surrounding fine material is of running consistence. This condition may be known by the abnormal quantity of material brought up to the surface, with no corresponding increase of depth. In such a case, if appreciable gold comes up with the borings, the only safe course is to reject that borehole and start afresh. Buried timber will be found the worst obstacle, and if a thick and solid log be found, it is seldom possible, or worth the while, to bore through it.

Complete notes should be made of every bore-hole, with a description of every obstacle, and of every variation of material. In describing clay it should be graded according to the greater or less difficulty in puddling it. Every three or five feet of core should be panned separately, and the resulting concentrate kept as a separate sample, and the gold separately determined. By this means the variation in gold value may be roughly estimated. This estimation of the relative enrichment of each horizon cannot be accurate in wet loose ground, because the action of the tools causes concentration toward lower levels, and, moreover, makes the line of contact between different beds indeterminate. If the bedrock is soft and rotten it is difficult, sometimes, to determine whether or not it is a band of alluvial clay or false bottom, and until the operator is well acquainted with the ground it is well to bore some feet into an argillaceous bottom.

Characteristics of the bedrock must be very carefully noted. A hard, rough, and uneven bottom will often put bucket dredging out of the question. A bottom of stiff clay, in which there is a large proportion of the gold, will also be a serious matter. On reaching a hard bedrock it should be bored into from two to four inches, after which a sample may be taken as follows: a handful of very tenacious kneaded clay should be pressed on the bottom of a wooden tamper tool, which is merely a cylindrical piece of wood an inch less in diameter than the borehole, and resembles a flat ended rolling pin more than anything else. The tool is then lowered and knocked lightly on the bottom twice. It should then be brought to the surface, and the clay puddled and washed, the process being repeated until no appreciable bedrock fragments are brought up. In boring the bedrock the tamper is not used until all that can be is brought up by the usual tools, but the tamper effectually seizes coarse gold, that would otherwise be neglected. Soft bottoms must be drilled into until colors are no longer raised.

*Abstract from *Australian Mining Standard.*

Use of By-Water Supply for Hydraulic Mining

By Dennis H. Stovall

No matter how rich the gravel, without an adequate water-supply used to the best advantage, a hydraulic mine is nothing more than real estate. Sometimes the mistake is made of using the entire water-supply for the battery, reserving none for 'by-wash'. This is false economy and proves a serious detriment, particularly in washing ground that contains many heavy boulders. No matter how much gravel is broken from the banks, little progress can be made if the sluices and bedrock races are not kept open. This requires plenty of water for by-wash. Some of the most successful hydraulic mines in northern California and southern Oregon use the same quantity of water for by-wash as is discharged through the giants. This appears like a waste of valuable water to the miner who has been accustomed to operating a big giant battery and using a small flow for by-wash; but it results in getting a greater quantity of gravel through the sluices within a limited time than can be accomplished by any other method.

A poor water-supply may be made good by proper handling; and a good supply can be made much better. If three giants are operated with a slight flow of by-water, and one or two of them must be turned from the bank two or three hours each shift to assist in clearing the race, much better results would be obtained by cutting out one of the giants and diverting its water into the ditch for by-wash. The flow of the latter will then be heavy enough to keep the race clear, and the remaining two giants of the battery will be free to work continually on the banks. Once a race is choked with boulders and débris, it can only be opened after the loss of much valuable time. The final clean-up is gauged, not by the quantity of gravel torn from the banks, but by the amount broken up and washed through the sluices. The by-wash plays just as big a part in this process as do the giants, and therefore demands as much attention. Where plenty of flow is given the by-water channel, it is still necessary that it be delivered as close to the point of operation on the gravel bank as conditions will allow. In this way huge boulders torn from the bank by the giants are picked up immediately and kept on the move. It is a fact well known to every placer miner that a boulder on the move gives no trouble; but that those allowed to stop flat side down must be 'bucked' from their resting place before the water can set them rolling. So the shorter distance between the point of operation and the entry of the by-water, the less work will be required to keep the race clear.

In the accompanying illustration, made from a photograph of a southern Oregon hydraulic mine, the flow of by-water is equal in volume to that discharged through the two giants. The by-wash enters the pit at a point only a few yards below the giants, and though there is an unusual number of heavy boulders in the gravel of this mine, they are easily handled.

Use of By-Water With Giants in Hydraulicking.

A method of using the by-water to the best advantage in mines where the flow is necessarily low, is by employing a self-shooter. This conserves the water and releases the accumulation at intervals. The periodic discharges break loose the stranded boulders and débris, and hurl the entire mass through the race. It is much like the occurrence of a freshet every half or three-quarters of an hour. It does effective work in keeping the race and sluices open, and at the same time does no harm to the riffles and boxes. The reservoir and automatic gate for the self-shooter can easily be built by any mine foreman, no other materials being required than those already at the mine. It can be constructed at any convenient point along the course of the by-water channel, but better results are obtained by placing it as near the

diggings as possible. At the lower end of the reservoir a gate is constructed. This is built of wood, and made to slide up and down between flanges, the main supports being two 6 by 8-in. timbers braced and driven firmly into the ground. Just over the gate a lever is hung between the two posts. A cable connects the short end of the lever with the gate, and from the long end an ore-bucket hangs. A joint of hydraulic pipe is set at the maximum level desired for the reservoir, and when this level is reached, the water escapes through the pipe and overflows into the ore-bucket.

When the bucket is full of water, or nearly full, its weight is sufficient to pull down the lever and lift the gate, thus releasing the water in the reservoir, which goes tearing down the race to break loose and carry away the accumulated boulders and gravel. A small cock is placed at the bottom of the ore-bucket, and so regulated that the bucket and the reservoir are emptied at the same or nearly the same time. When the water in the bucket is released, the gate, which is heavier, drops into place again, and the reservoir fills as before. After a few trials the self-shooter can be regulated to operate perfectly, and will require little or no attention.

A HASTY CONCLUSION

Our readers will, we are sure, appreciate the humor of the situation revealed by the following letter referred to us, without comment, by L. E. Aubury, State Mineralogist. The offending item was originally published in 1865 and was re-published under the old date line in our Anniversary Number, as an illustration of former conditions. If Mr. Gregg had read the paper with any care he would have saved himself disappointment. However, he has had a trip to Yuba county, and that is worth something to anyone.

July 1, 1910.

Mr. Lewis E. Aubrey, S. M. Burea, S. F.

Mr. Aubrey:—I went to Smartsville thinking I could do something with an extensive hydraulic operation which the *Mining and Scientific Press* stated was going on there. If you will refer to the issue of May 21, 1910 p 768 under heading Yuba County you will find stated that the Blue Gravel Company has had clean ups of $46,000, $26,708, and $50,786 this year and that last year the earnings were over $200,000.

The fact is that for three years (I have been told) there has been some effort to exploit an old property there at considerable expense with problematical schemes, and so far from clean-ups are they that there has been no water for washing gravel even on a small scale, the projected ditch is not yielding water and it is not likely to for some months. I was told that it is the only mining operation about Smartsville.

Somebody has evidently made a fake, a fraudulent news item, and it would seem the the *Mining and Scientific Press* is to blame. Truly

WILLIAM GREGG.

224 Mill St. Grass Valley Calif.

Deputy Mineral Surveyors and Mineral Locations

By H. W. MACFARREN

It is well recognized that United States deputy land and mineral surveyors by the knowledge gained in the performance of their official duties, in their access to records, and in their ability to obtain advance information, are in a position to make desirable entries on public land, and are under considerable temptation to act fraudulently and corruptly to their pecuniary advantage in this respect. The deputy mineral surveyor sees many opportunities to locate mining claims or make other entries or filings. In surveying for patent claims that have been staked too large, there is the temptation to become a silent partner in the location of the fractional claim or claims left, to the injury of the client who is properly entitled to make these locations. This happened recently in a Nevada camp, where the chainman located such a fraction which contained the apex of an important orebody, but it was probably the chronic carelessness of the deputy rather than any corrupt motives on his part that allowed this. The Government attempts to protect itself and the public against venal deputies by requiring that its appointees be of good moral and professional reputation, and by enforcing the laws and regulations to a degree which is often a source of ridicule by those who have not carefully studied the subject.

The Government early foresaw the mischief and poor morals that would result if certain of its employees were not removed from the temptation to deal in public land, and in consequence enacted section 452 of the Revised Statutes, which with the subsequent circulars and decisions of the General Land Office constitutes the present law on the subject. The section reads: "The officers, clerks, and employees in the General Land Office are prohibited from directly or indirectly purchasing or becoming interested in the purchase of any public land; and any person who violates this section shall forthwith be removed from this office."

In a circular (11 L. D., 348) referring to the above act, the Commissioner of the General Land Office said: "In accordance with said decision, all clerks, officers, and employees in the offices of the surveyor-generals, the local land offices, and the General Land Office, or any persons, wherever located, employed under the supervision of the Commissioner of the General Land Office, are, during such employment, prohibited from entering, or becoming interested, directly or indirectly, in any of the public land of the United States." In a later circular (34 L. D., 605) the Commissioner more rigidly drew the restriction by saying. "Acting under the spirit of this law and the decisions referred to, this office will recommend the removal or dismissal of any of the above-named officers, clerks, or employees who shall, whether for themselves or others, in an manner negotiate for, buy, sell, locate, any warrant, scrip, lieu land selection, soldier's additional right, or any other

negotiable right or claim under which an interest in the public land may be asserted, as well as such officers, clerks, or employees who shall, except in discharge of an official duty, help or in any manner whatever furnish any information to or in any manner be in communication with any person, firm, or corporation dealing in such rights, in relation to such rights.

While Sec. 452 of the Revised Statutes does not prohibit the acquisition of title to public land of the United States under appropriate laws by the wives of officers, clerks, or employees of the Land Department, it is not deemed advisable or proper in the interest of good administration that they should do so. Accordingly, such purchase or acquisition of title, directly or indirectly, to any of the public land by their wives, prior to the separation from the service of such officers, clerks, or employees, will be deemed a sufficient cause upon which to base a recommendation for removal or dismissal from service of the officer, clerk, or employee whose wife acquires or seeks to acquire title to any of the public land." The Secretary of Interior said in the case of Sherrard Coleman (18 L. D., 394), who, while under contract with the Department of Interior for the survey of certain public land and in consequence a United States deputy surveyor, filed a declaratory statement to purchase certain coal land, "In the prosecution of his work the deputy surveyor is clearly under the control and supervision of the surveyor-general; as a deputy he has access to the records in the office of the surveyor-general, and the compensation he receives comes from that officer. I am of the opinion that Coleman was disqualified from taking any part of the public land while a deputy United States surveyor, and hence his filing should be canceled." In the case of Robert J. Watson (33 L. D., 435), who filed application to purchase timber land while commissioned by the Secretary of Interior as a Forest Ranger of the General Land Office, the Secretary of Interior said to the Commissioner, "it clearly appears that claimant was an employee of your office, and hence disqualified by statute from making the entry in question." The Secretary declined at that time to pass upon the question of the claimant being allowed to resign his commission and perfect his entry.

The substance of three decisions, (24 L. D., 393; 29 L. D., 76; 29 L. D., 333), is that deputy mineral surveyors are land office employees and together with surveyor-generals are disqualified as mineral entrymen. That entries for patent to mining claims made by them are to be canceled, while in those cases where their names appear among other co-applicants, patent will be allowed only after their names have been removed from the application. In the case of Floyd *et al* *v.* Montgomery (26 L. D., 122), the same was held and a further step taken when it was said that attention would be given to the recommendation looking to the revocation of the commission of the deputy mineral surveyor who officially reported on the claim to the surveyor-general while holding an interest in it. A more liberal interpretation of the statute was given in the case of W. H. Leffingwell (30 L. D., 139), "A deputy mineral surveyor who has no interest, real or contingent, in a mining claim at date of survey thereof by him, nor at date of application to patent thereto, but who subsequently makes entry thereof, does not come within the spirit of section 452 of the Revised Statutes." In this case the deputy obtained an interest in the claim, which he had not contemplated taking before, after the application was first made for patent, and was the principal in the final entry necessary in patent applications. The Secretary of Interior held in the instance of Seymour K. Bradford (36 L. D., 61), "Under the authorities a deputy mineral surveyor is within the purview of said section 452, and consequently is prohibited from making a mineral location, upon penalty of the forfeiture of his official position. It may be that Bradford acted without actual intention to violate the Statute, but ignorance excuses no one. That the locations made may be defeated or proved to be voidable does not clear him. He, while a mineral surveyor, was directly and beneficially interested, as a co-locator, in the City Bank placer claim in violation of the Statute and of necessity the penalty, to-wit, his removal from office, must follow. The appointment of Seymour K. Bradford as a United States mineral surveyor must be revoked." It was said in the case of Philip Contzen (37 L. D., 489), a deputy mineral surveyor who made a homestead entry upon public land, "The making of an entry of public land by a deputy mineral surveyor will be sufficient cause for the revocation of his appointment as a deputy mineral surveyor." No mention was made as to whether the entry would be canceled.

Whether a mining location made by a deputy mineral surveyor is valid or invalid is a point that the Department of Interior has discreetly avoided passing upon. The Utah court in the case of Lavigno *v.* Uhlig decided that such a location was void, while a Nevada court held the contrary on the unquestionably erroneous conclusion that deputy mineral surveyors are not land office employees. A careful study of the wording of the two circulars quoted before leads to the belief that if the Department were called upon to decide the specific point, it would without hesitation hold that such locations were void. Costigan in his admirable work on mining law refers to the necessity of protecting innocent purchasers of such locations, and infers that the location should be voidable by the Government only, placing it in the same category as a location made by an alien. But the location of mineral ground by an alien is seldom, if ever, inconsistent with the best interests of mining, and the Government acts accordingly, while a location by a deputy mineral surveyor, even if it hampers no one in the execution of their desires, is not in accordance with sound public policy or productive of good public service. In view of the more recent and present strict interpretation and enforcement of the laws and regulations, it is probable that the deputy who makes a mining, agricultural, or other location, entry, or filing upon public land, will suffer both the loss of his commission and the cancelation of the entry.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

An efficacious antidote for cyanide poisoning is several drops of ammonia on sugar, eaten immediately. In cases of external poisoning a bath in warm water containing bicarbonate of soda and common salt is recommended.

The placer deposits of the Bearpaw mountains in Montana are of very little importance, although some coarse gold has been recovered by panning and sluicing of some of the small gravel bars occurring along drainage ways throughout the group.

A catalytic agent is a substance which promotes a chemical change, or interaction between two substances, without itself suffering any permanent change. The change may be of a positive, accelerating, or of a negative, retarding, character.

Concrete for machinery foundations is often mixed in the following ratio: 22½ cu. ft. 2-in. rock, 7 cu. ft. ½-in. rock, 13 cu. ft. washed sand, and 1⅛ bbl. cement. The surfaces and covering of the blocks should be considerably richer than this in cement, the amount being almost doubled. Concrete battery foundations are now standard and are the only really satisfactory ones for heavy stamps.

The cost of sulphuric acid depends on the price of coal, pyrite, and saltpetre. That being the case, it would appear probable that Utah and Colorado, owing to their proximity to almost inexhaustible supplies of pyrite and coal, will become in time, important producers of sulphuric acid. There exists in Utah and Nevada important deposits of nitre which for various causes have not been exploited.

The change from one polymorphic crystal form of a substance to another in some instances takes place with great slowness upon change of conditions; in other places rapidly. In some cases the transition may take place in either direction upon changes of conditions; the process is then enantiotropic. In other cases the process is possible only in one direction, from a metastable to a stable condition. Such a process is monotropic.

From tests of trap and other rocks, it is seen that a material saving can be effected by the use of trap for ballast purposes. Less stone will be required to maintain the track, and it can be used in smaller sizes, as its higher percentage of hardness and toughness insures less breakage under traffic. Figures taken from comparison of line and surface in trap with that in stone whose quality is about the same as limestone, show that line and surface cost approximately $20 less per mile in trap than in limestone.

In the daily control of millwork, particularly that of an experimental character, it is desirable to make the labor of computation as light as possible, so that results for rate of crushing or the contents of a vat can be read off rapidly after making the required observations, such as weighing pulp. For this reason it is convenient to have a suitable table prepared to meet any special case, and an hour or two spent in making such a table will be saved many times over in the subsequent work when systematic experimentation is carried on.

The Bureau of Forestry has established regulations governing the appropriation of water-powers located on streams which drain watersheds included in whole or in part in forest reserves. Among these regulations is the imposition of a graduated rental, to be paid by the individual or corporation appropriating the water-power and used by the Government for forest purposes. This rental rests upon the assumption that the appropriator of the power will be benefited by the preservation of the forest, and this idea is accepted generally by engineers and by the public.

The advantages in filling in underground work are: little timber is required, the complete extraction of ore in the lode, all waste rock is stored in the mine, a fairly clean product is sent to the surface, ease of stoping and reduced cost of mining, the repeated use of filling for support of mine workings, and the placing of levels considerable distance apart. The disadvantages are: its application is limited largely to steeply inclined lodes, cost of building pack-walls, considerable handling of the ore in stopes, collapse of upper level on withdrawal of filling and danger of a crush starting and extending to the lower levels, and loss of ore by mixing with waste in cutting out arch pillars.

Mill-men in various districts often fail to agree as to the proper grade to give mill plates, their ideas ranging from 1 inch or less to as much as 2½ inches, or more to the foot. This difference in opinion among men who should know, probably represents the extent of their personal experience in the districts where they have worked. The fact is, the character of the ore must determine the grade of the plates, and the proper amount of water to use as well. An ore heavy with sulphides, or other mineral of high specific gravity, requires a heavier grade of plates than ordinary quartz ores, and also demands a larger amount of water in the battery than the latter.

Ocher as the term is ordinarily used is applied to the earthy and pulverulent forms of the minerals hematite and limonite. It is always rendered more or less impure through the presence of other metallic oxides and of argillaceous or clayey material. Natural ochers show a variety of colors, which depend on the chemical composition, in general. Hematites give red ochers and limonites give yellow, buff, or brown. The amount and kind of impurities also influence the color. In brief, the natural color of ocher depends on the degree of hydration and oxidation, and the kind and quantities of impurities. As the color of ocher depends mainly on the degree of hydration, a red ocher may be made by calcining common yellow ocher.

Special Correspondence

LONDON

Palmarejo & Mexican.—Butters-Salvador.—St. John Del Rey.—Selukwe.—Broken Hill Proprietary.

The Palmarejo & Mexican Mining Co., owning silver-gold mines in Chihuahua, has been before the London public for nearly a quarter of a century. In the early days at least one of the leading American mining papers had a good deal of advice to give English investors with regard to this project and uttered notes of warning with regard to the character of the men in charge and also in connection with the alleged value of the ore. The warning fell on deaf ears, with the consequence that large amounts of capital were recklessly squandered. Eventually the incapable directors and engineers were removed, and afterward several men of position made attempts to improve the methods of mining and metallurgy. It was found that the orebodies were irregular though extensive and the content low, averaging 2 dwt. gold and 15 oz. silver. The ore was of too low grade for amalgamation and would not give good results by any cyanide process known at the time. Eventually, two years ago, E. T. McCarthy's advice was taken, and he reported that the process now in use in Nevada and in other parts of Mexico would be applicable to Palmarejo ore. He examined the property and indicated the best lines for exploration and development. The chairman, John Parry, has just returned from Mexico and has given the latest information. The development work has exposed 140,000 tons of ore averaging 2.4 dwt. gold and 14½ oz. silver, and at several points the orebodies give indication of further reserves. It is intended to continue developments for a few months longer and then to erect a new metallurgical plant. In the meantime the old plant has been cleared and the foundations prepared for the new; and plans have been adopted for an aerial ropeway to connect the mine and mill. Mr. McCarthy reports that a greater quantity of ore had been found per foot of development than he had originally anticipated, and that consequently the 5665 ft. has cost only 2s. per ton of ore developed. Taking the content at 38s., Mr. McCarthy expects that the profit will be 18 to 20s. per ton. More money has been and will be required, so the capital of the company has been re-arranged. A third series of debentures for £30,000 was issued recently in order to provide funds, thus making the total debentures £80,000. The nominal capital has been reduced from £875,000 to £350,000 by the cancelation of 15s. on each of the 700,000 shares of £1 each. The capital consisted of 700,000 £1 shares and 700,000 5s. shares, all ranking equally for dividend purposes. The 5s. were issued in 1999 on these favorable terms, as a substitute for reconstruction. Of these two classes of shares 679,063 of the £1 shares were issued; the whole of the 5s. were issued and 2s. 6d. called up. The subscribers to the third debentures have the option of taking any unissued or unsubscribed shares in exchange for the debentures.

Progress at the Butters-Salvador gold mine is excellent. The English company was formed in 1899 to acquire gold mines opened up by Charles Butters in the Santa Rosa district, Republic of Salvador, Central America, 40 miles from the port of La Union, and until recently the doings have not been advertised here, consequently details have not been generally known. Two orebodies have been worked, the San Sebastian and San Miguel; these are probably connected and exploration of the ground between the two is now being undertaken. Mining is done by adit, and the main level is 600 ft. below the highest point of the outcrop. The capital is £150,000 and dividends were first paid in 1903, when 5% was distributed for the year ended June 30, 1903. Succeeding yearly dividends have been at the rate of 55, 40, 55, 75, 80, and 68¾%. The amount of ore treated during the past year was 21,664 tons and the yield was 38,504 oz. The sale of bullion realized £151,520. Mining, milling, and cyaniding cost £55,037, depreciation £3590, mine development £15,532, and London, New York, and San Francisco expenses £7705. The divisible profit was £68,129, and with £54,038 brought in from the previous year made an available profit of £122,167. Out of this £103,125 has been distributed to shareholders, the rate being 68¾%. The most recent cable, made public a few weeks ago, showed that developments have greatly added to the reserve, which now amounts to about 100,000 tons averaging 33 dwt. It is probable that in the near future more will be heard of the shares in the London market.

The St. John Del Rey Co., operating the Morro Velho gold mine in Minas Geraes, Brazil, was formed originally in 1830. The report covering the year ended February 28, shows that 185,837 tons of ore was raised and after sorting out 2.6%, 181,000 tons was sent to the battery of 120 stamps. The yield in the stamps and by the succeeding 'oxygen' process was 104,003 oz. or 45s. 9d. per ton, the total realizing £416,330. In addition, from the Cuiaba mine gold valued at £21,783 was recovered. The working cost was £277,161, development £14,702, taxes, etc., £20,490, and London expenses £3899, leaving a profit of £121,861. Out of this £55,849 was allocated to expenditure on new works in connection with electric power, £5458 was paid as interest on debentures, and £10,583 as dividend on the preference shares. The distribution on the ordinary shares was £48,177. These amounts paid to debenture and shareholders include English income tax; after deducting the tax the rates of interest or dividend are 7, 10, and 8⅓%, respectively. The directors are now proposing to create 100,000 second preference shares of £1 each, carrying 10% dividend, in order to provide the necessary funds for discharging the debentures, of which £31,475 fall due in 1911 and £36,275 in 1913. Though these are created, it is not likely that many will be issued, as most of the debentures are to be renewed. It is noteworthy that the yearly amount of ore treated is gradually increasing, a fact due largely to the efficiency of the new electric haulage system. The tube-mills recently installed have improved the extraction by the 'oxygen' process, but they are found to consume much power, an expensive item at St. John Del Rey. The question of the life of the pebbles used for grinding is an interesting one. Imported flints and local silicified iron carbonate have been used. The former last five times as long as the latter, but the relative prices delivered are £9 and 17s. 6d. The pyritic concentrate is twice the specific gravity of the pebble and the iron carbonate is practically of the same specific gravity, the grinding efficiency of the latter being therefore much greater. The iron carbonate has also the advantage of containing a small amount of gold, most of which is recoverable. The report of the engineer, George Chalmers, contains an unusual amount of interesting details relating to the conditions of the mine.

The Selukwe gold mine is one of the oldest in Rhodesia, having been working since 1898, and during the years 1902-3 dividends were paid. Later the quality of the ore decreased, and last autumn the mine showed signs of exhaustion. The Chartered company and the Bechuanaland Exploration Co. came forward and guaranteed the issue of 100,000 new shares of 5s. each for the purpose of further capital wherewith to continue prospecting and development. At the same time, A. H. Ackermann, the Chartered company's engineer, proceeded to the mine to direct operations. A report by Mr. Ackerman, dated May 21, has been published stating that devolepment had not revealed any profitable orebody, but a cable dated June 20 has since been published announcing that 80 ft. driven on the tenth level of the Nigger Reef property had assayed 8½ dwt. over a stoping width of 4½ ft. The discovery makes the outlook more encouraging.

The Broken Hill Proprietary is treating its dumps for zinc concentrate by means of the flotation process, and is earning a handsome revenue from these two sources. At the same time it is not depleting its ore reserves while the prices of metals are low. The company is starting in a small way to make spelter at Port Pirie. The works there have been placed under the charge of Mr. Arneman, a Belgian expert. The preliminary work done is described as having caused far less difficulties than usual in starting a new industry.

That there have been difficulties is admitted, but in view of the well known conservative nature of the management it is recognized that such an announcement means that very satisfactory progress has been made. As far as the other mines go they are all developing well except at the Junction North mine and the Block 10 where it is becoming evident that the orebodies do not extend to the depth hoped. It is somewhat premature to express a definite opinion as to the outlook of the whole field, but developments at these two claims seem to indicate that there may have to be a re-casting of estimates in respect to the future of Broken Hill.

JOHANNESBURG, TRANSVAAL

Marriott's Square Fathom Scheme Criticised.— Mein Favors Old Basis.—Central Administration Returns.

Additional interest has been lent to the 'Tons *v.* Square Fathom' controversy through a paper by W. W. Mein, who has for some time past been general manager of the Eckstein's Central Administration group, which includes such important mines as the Robinson, Village Main Reef, Village Deep, New Modderfontein, and Ferreira. Mr. Mein vigorously challenges the accuracy of H. F. Marriott's remarks on the abuse of the per ton-milled unit, disputes the whole case brought forward in support of the square-fathom basis, and argues that the system of recording results on the square-fathom basis instead of on the ton-milled as heretofore, and of issuing a statement as to the results secured per quarter instead of per month as heretofore, is from a practical point of view inapplicable to Rand mining. It will be recalled that a few months ago L. Reyersbach, of Eckstein & Co., when banquetted on the occasion of his leaving Johannesburg, threw out the suggestion that monthly returns should be superseded by annual returns. The suggestion raised a perfect storm of indignation in London and on the continent, and it was so patent that European shareholders were so strongly opposed to remaining in ignorance for months as to the performances of the mines, that the matter was dropped. But Mr. Marriott (who evidently came out here with full power and authority from the great firm of Wernher, Beit & Co.) has revived interest in this matter. He does not speak of yearly returns, but in certain usually well informed circles it is believed that the introduction of quarterly returns would be merely the thin end of the wedge in an endeavor to secure annual reports only. Mr. Mein's view is that it will remain obligatory for managements to maintain a detailed system of monthly records, "not only because of the large payments made monthly in respect to wages, but because any manager who did not make a close analysis of the position in the light of detailed records every month would be unable to exercise adequate control over changing conditions. His mine would get out of hand." It is common knowledge that for some time past the technical controllers of the Main Reef mining industry have been split up into two camps—the one side staking faith in the big mill, low-grade ore, and low cost policy, and the other favoring cleaner mining, the running of the mills to suit the mines rather than the reverse, and the recovery of a considerably greater amount of gold per ton although at a relatively high rate of expenditure. Of course the wisdom of each course has to be considered in special relation to each mine or each group of mines. What might be the best policy to pursue at one mine might be the worst for another. Those who have discussed the 'big mill' scheme with such denunciation that there is a strong insinuation of dishonesty in their criticism, have not been either just or considerate in their remarks. On the Rand are some of the best and most conscientious managers in the world, men who do their best to serve their employers, and I venture to remark that there is not a manager here today who is not doing his best in accordance with the policy laid down for him. Rand mining tendencies are not the outcome of policies devised at the mines themselves—not to any appreciable degree at any rate. Policies are thought out in London or the Johannesburg head offices, and it is the duty of the manager to abide by the method of working devised by his superiors. Should he believe that the scheme of operations devised is prejudicial to the mine he can of course raise his voice in protest, but in the case of a mine equipped with 300 stamps and where a policy of low-grade milling has been adhered to for some time, it is not always an easy matter to bring about a complete revolution of policy. It is worthy of note, however, that at the Robinson Deep there has been recently a reversal of policy. Rather than break ore in excessively wide stopes, 85 stamps out of 300 erected have been hung up and thoroughly adhering to a policy of cleaner mining, the returns of the company have been improved. When more labor is available the company will re-start the idle stamps. At the West Rand Consolidated, however, when confronted with a similar position a few months ago, it was decided to put machine drills in the stopes and run the mill on low-grade ores. Mr. Mein has striven hard for low costs and big tonnages, and in his

Central Administration Building Rand Mines.

paper he shows the following comparison between the years 1906 and 1908 for the mines of the Central Administration group:

	1906.	1908.	
	s. d.	s. d.	s. d.
Cost per ton milled.....	22 5	17 5	Decrease 5 0
Yield per ton milled....	38 10	37 5	Decrease 1 5
Profit per ton milled....	16 5	20 0	Increase 3 7

The increase in profit is £730,000, or exactly 50%. "This must surely be considered a beneficial result of the craze for keeping the full mill going, and greedily asking for more stamps," writes Mr. Mein. The paper is certain to evoke lively discussion. It would appear that the firm of H. Eckstein & Co. is not going to adopt Mr. Marriott's recommendations, not *in toto* at any rate. It is probable that in the annual reports of certain companies, a feature will be made of development, ore reserves, stoping, and driving on the square-fathom basis, and attention will be directed to these features at annual meetings. Apart from this, however, no change in policy seems likely in so far as the declaration of returns is concerned. In concluding his paper Mr. Mein makes the following summing up of his opinion of the agitation for the square fathom and the abolition of the working costs per ton milled consideration. "In bringing forward this new scheme Mr. Marriott has urged us vigorously to waste no time over the 'dead carcass' of working costs per ton milled. It is as dead, he tells us, as the proverbial door nail. Meeting metaphor with metaphor, I will, in conclusion, merely risk the prediction

that the new fathomage basis of mine returns, once its deformities are recognized by those endeavoring to set it upon its feet, will be found unable to bear the burden of its full responsibilities and will pass its frail existence humbly and impotently riding on the back of the regenerated 'carcass" of the tonnage system."

SEATTLE, WASHINGTON

Gold Receipts. — Mining in the Cascades. — Tacoma Smelter.— Alaska Mines.—Stewart District.

The gold bullion receipts from Alaska at the U. S. Assay Office at Seattle for the fiscal year ended June 30, 1910, were as follows: Nome district, $4,167,304; Fairbanks district, $5,676,477; other districts, $948,744; total, $10,792,525. As some shipments from Alaskan points were made direct to San Francisco, the above figures fall considerably short of representing the aggregate value of gold bars and gold dust sent out of Alaska for the year. Further figures show that between July 15, 1898, and July 1, 1910, Nome has sent, in round numbers, $42,000,000, Fairbanks $37,000,000, and other Alaskan points $8,000,000, to the Government assay office at this place.

The neglect of the Cascades in western Washington as a metal mining country has been due in part to alluring placer goldfields in Alaska to which Seattle men have been going for more than a decade. That some promising veins of copper, silver, lead, and gold ores have been opened in these mountains seems beyond question, yet Seattle men do not take readily to exploration in this rugged and heavily-wooded range while the ships ply between here and the frozen streams of the Far North. Reliable reports of a mining engineer who recently visited Wenatchee, in Chelan county, vouch for the discovery in that vicinity of a gold-bearing zone of quartz and rhyolite more than 200 ft. wide, which samples $2 per ton, the gold occurring free. This is one of numerous examples of worthy prospects in the Cascade mountains. While mining operations in the Cascade range, in Washington, are not aggressive, conditions in the Northwest generally are hopeful and healthful. While few enterprises are being promoted and there is but little life in the mining stock market, there is a considerable amount of development going on; and the shipments of ore to the smelters at Tacoma and Ladysmith demonstrate that the active mines of the Northwest are keeping up and in some cases increasing their production. The Tacoma plant is receiving about its usual tonnage of lead-silver ore and concentrate from the Coeur d'Alene district; it is receiving a considerable part of the 4000 tons per month of silicious ore mined in Republic district. The ores produced on Texada island, British Columbia, amount to a considerable tonnage, the principal mines being the Marble Bay, Copper Queen, Cornell, and Little Billie. These ores consist of a copper sulphide, accompanied by some gold and silver. The La Touche mine, situated on La Touche island, in Prince William Sound, Alaska, has been taken over by the Beatson Copper Co., which purposes developing on a greater scale and increasing its shipments of copper ore. It is also understood that the Ellamar mine, in the same part of Alaska, is to begin ore shipments in August, or as soon as the coffer dam, now under construction, shall be finished. The ores produced on Prince William Sound are shipped mostly to Tacoma, while those mined on Prince of Wales and Texada islands are divided between Ladysmith and Tacoma. The shipping mines on Prince of Wales island, near Ketchikan, are the Sulzer, Mt. Andrew, It, and Goodrow, with others developing. The Dunton mine, at Hollis, on this island, produces gold ore which is milled on the ground, the owners being M. K. Rodgers and associates of Seattle. The others mentioned yield ore having a copper-iron base, carrying other metals.

Interest in the Stewart district, situated at the head of Portland canal, is reflected in the activity at Vancouver, British Columbia, by way of organizing companies to acquire and develop mineral claims in that district. An engineer who had visited Stewart to look over the country stated that the indications were good, but that everything was very new as to development.

ELY, NEVADA

Nevada Consolidated. — Nevada United to Issue Bonds. — Ely Calumet.—Ely-Goldfield Railroad.

Notwithstanding the low price of copper there has been no abatement in the output of the Nevada Consolidated. In fact, every month since March has shown a steady increase, until the output is now running well above 6,000,000 lb. per month. On July 9, 203 cars of ore, averaging 55 tons each, were shipped from Copper flat to the concentrator, making a total for the day of 11,165 tons. The general average of the month so far has been considerably in excess of 9000 tons of ore per day, which, if kept up for the remainder of the month, will prove a new record for the camp in the production of copper. Another pleasing feature from a local viewpoint is the fact that an official statement issued by the company places the cost of production for the month of May at 5.95c. per pound. This, for a company that has been making copper but two years, is certainly a revelation to other and older producing companies, and will go far toward establishing the supremacy of the porphyry-copper mines. It proves that the Nevada Consolidated is now on an earning basis of $4,800,000 per year. It is paying dividends at the rate of $3,000,000 per year, which can be increased 50% on the present price of copper.

It may now be considered as a reasonable certainty that a railroad will be constructed during the present year from Ely to Ward, twenty miles south, to connect the mines of the Nevada United company with the Nevada Northern railroad. The company has a million and a half tons of lead-silver ore blocked out in its property, which will average about 25% in lead and from $8 to $15 per ton in silver. The shareholders of the company at a meeting in Denver voted to issue bonds for a sufficient sum to build the road and equip the property with an aerial tramway and ore-bins. A preliminary survey for the road was recently made by the company, which is being checked over by engineers who are supposed to represent the Nevada Northern railroad. Mr. Berry, of New York, an engineer who is a subordinate to Pope Yeatman, consulting engineer for the Nevada Consolidated, is also at the property checking up the tonnage blocked out in the mine. H. Byrd Northrop, treasurer of the company, who resides in Denver, has been at the camp for the past week, and is assisting the engineers in their work. Two years ago the Nevada United company shipped 30 or 40 carloads of ore to the Denver smelters, from which it received a most satisfactory return, but as the wagon haulage from the mine to the railroad amounted to $4 per ton the management decided to defer shipments until it could secure the construction of a railroad, and apparently the time has now come for its construction. Development work has been continued steadily since that time.

C. S. Herzig, consulting engineer for the Ely Central, is spending the week here and is well pleased with development since his last visit. About four weeks ago a find of considerable importance was made on the property of the Ely Calumet company by lessees. The drift has been driven along the lead, which is 3 ft. wide, for a distance of 40 ft., and samples of the ore show that it contains 25% copper. Near the face of the drift a winze has been sunk 10 ft. from which 30 tons of ore were taken which samples as well as that in the drift. This is the richest ore found in the district, except that taken from the 1200-ft. level of the Giroux. The property is situated immediately north of the town of Ely and is on the extreme eastern end of the copper belt. The formation is principally limestone overlying monzonite to a depth of several hundred feet, and is traversed in an easterly and westerly direction by fault-fissure veins, showing quartz and iron outcroppings in many places. The veins have been crushed and brecciated between the walls of limestone, making it possible for the mineral solutions to penetrate and precipitate the metals in the softer formation of the fissures. The eastern end of the belt has been neglected for years by mining men, who were of the opinion that the limestone did not contain cop-

per deposits of importance. The company, it is announced, will open its entire property, consisting of 28 claims, for leasing, and as good ore is showing in many places on the surface it is likely that many lessees will soon be at work on the company's ground. The first payment of $10,000 was made July 9 by S. Herbert Williams and Harry Eastwood on the Turner Ely group of claims upon which they recently secured a bond. The property lies immediately south of Lane City, two and a half miles west of Ely, and is considered as one of the best steam-shovel propositions in the entire district. The sulphides in many places crop on the surface, and it is said by men familiar with the property that they will average from 8 to 12%. It is the intention of the present owners to commence development work on the property in the near future.

It now seems probable that the long talked of Ely-Goldfield railroad will be a reality in the near future. It is known that F. M. Smith has recently returned from Europe, and he has announced that the road has been financed. A permanent survey for the road was made last year from Cuprite, fourteen miles south of Goldfield, to Ely by way of Tybo and Current creek, but it is now thought that the road will run nearly directly north from Tybo to Hamilton, with a branch west of Hamilton to Eureka, which has been without a railroad since the washing away of the Palisade-Eureka road in March last, and which so far there has been no effort to rebuild. Eureka and Hamilton are two of the largest tonnage camps in the State. The mines at Eureka are owned by the United States Smelting company, the ores from which have been shipped to the company's smelter at Salt Lake at the rate of 200 tons per day. The ores are lead-silver bearing and are greatly in demand at the smelter for flux. It is thought that the delay in the reconstruction of the old narrow-gauge road from Battle Mountain has been largely due to the probability of the early construction of the Ely-Goldfield road, which would give the camp of Eureka a standard gauge road, and thus do away with transferring the ore at Battle Mountain.

ST. PETERSBURG

New Oilfields. — English Investments. — Lack of Order. — Quality of Oils.

The following statement of the position of matters as between the people of this country interested in oil either as investors or speculators and the petroleum industry in the Kuban region is one containing not only statements of quite well known facts, but also showing the way that must be followed if the Kuban petroleum industry is to issue from its early stages into a developed business and avoid the checkered and frequently disastrous experiences through which Grozny, with remarkable richness in petroleum, has had to pass up to its present position of relative prosperity. Grozny is nearer the Black Sea than the Caspian, and finds its most convenient port in Novorossisk, that is to say, it is a Black Sea petroleum area, and more than once in its history black ruin has stared the petroleum producers there in the face. Subsequent to, and not unlikely because of the extraordinary troubles at Baku in 1905 which caused petroleum to rise to a phenomenal price, Grozny has lately developed its resources and during the last few years has achieved record productions, reaching now to over 50,000,000 poods per annum, or over 10% of the total Russian production of petroleum.

The Maikop petroleum deposits have the advantage of being still closer to the sea, and therefore within easier reach of the world's market. The operators will probably not have to go through the experience of the Grozny people, whose struggle with water caused heavy loss as well as legal proceedings, but if the business is to develop on healthy lines it must go out of the hands of the speculator and into the control of the investor and the expert. At Maikop claims have been bought and sold without any regard to their value, and it has been quite a common thing for both buyer and seller to be quite unable, after important sums of money have changed hands, to indicate the spot that had been dealt in. Both last year and the present one will ever remain memorable in the history of the Russian petroleum industry because to the interest taken in petroleum deposits to be found in the Kuban Province. Properly speaking, at the beginning of the excitement over this business it was simply a question of the so-called Maikop region which is situated to the south of Kuban, but the petroleum gusher which was struck in the early days of September last year in the Maikop region so stimulated general interest in petroleum that people began to seek for it in the northern part of the region as well. Then finally petroleum searchers covered the whole of the Kuban Province from the Maikop field in the south to the lower courses of the Kuban and Taman in the north.

The result of this movement of interest in Kuban petroleum at the present moment is that the charts of allotments over the area present the feature of a chess board; for there is hardly throughout the whole Kuban Province a single spot of ground where some enterprising man or another has not placed his sign-board or claim, while in the vastly preponderating number of cases he has not taken any time to inquire whether his claim may or may not be on petroliferous land. Without the slightest exaggeration it may be said that now the Kuban Province is covered with a thick forest of claim 'pillars' and it is unfortunately to be stated that in a whole series of cases such claim pillars have brought solid profit to those who have fixed them. Finally those persons who have acquired money in this way find themselves in a favorable position for the moment, but this success must doubtless be considered as placing something of a burden on the future of the Kuban petroleum industry. It is, for example, only recently that news has come from London that the English have considerably cooled in respect to the Maikop petroleum business and they do not wish to hear more of the Maikop claims. Such an indifference toward Kuban petroleum on the part of English capital is quite easily understood. In a great number of cases English investors have had offered to them quite worthless sections of land and their valuelessness is a question both of geological formation and of legal rights. To calculate exactly how much capital has been invested up till now by the English in the Maikop business is impossible; but there are indications that the nominal amount so invested has reached something like 200,000,000 roubles ($106,250,000). According to the list of registered companies in England the capital paid in is less, somewhere between 60,000,000 and 100,000,000 roubles. But whatever sum has to be deducted from the above figure we must recognize that the balance is large. How far such capital is genuine is another question, and in this respect we must recognize that in the cooling off of English investors in the Maikop business Russian unprincipled 'claim stakers' are guilty besides many English dealers who, having considered the business from a purely speculative point of view and having formed such companies, were ready to undertake anything profitable excepting the production of petroleum in Kuban. Up to the present time at least, notwithstanding the undoubted transfer into English hands of a large area of the Kuban Province, very little is heard of serious work undertaken with the object of obtaining petroleum, and even in England in the reports of several companies which have appeared for the exploitation of petroleum in Kuban, we find only information of the revenue of these companies obtained by the issue of fresh shares and so on, which is a purely stock exchange operation. Thus, for example, we find the account of the general meeting of the shareholders of the Maikop & General Petroleum Trust, Ltd. in which the directors very elaborately dwell on these revenues which they have realized, having formed (although their own company has scarcely come into existence) four new companies, the Maikop Valley, the Anglo-Maikop Corporation, the Maikop Producers' Co., and the Maikop Mutual Oil Transport Co., while as to the existence of reserves of petroleum on the allotments of the respective companies or as to boring and general work very little indeed is said in the report referred to.

With reference to this matter I do not take upon myself

revenues which they have realized, having formed (although their own company has scarcely come into existence) four new companies, the Maikop Valley, the Anglo-Maikop Coporation, the Maikop Producers' Co., and the Maikop Mutural Oil Transport Co., while as to the existence of reserves of petroleum on the allotments of the respective companies or as to boring and general work very little indeed is said in the report referred to.

With reference to this matter I do not take upon myself to throw discredit in any way on the solidity of the said company; nevertheless the domination in that report of the stock exchange operations over the genuine work on the spot is in any case unhealthy. To us Russians it is impossible to forget that petroleum in the Kuban Province has been known for a long time. For example, in Kudako on the Iiska there was once obtained a good quantity of liquid mineral; nevertheless the Kuban petroleum industry did not develop; but came to an absolute stop. As in the case of Kudako so also in that of Iiska the opinion is that both these concerns terminated unfortunately because they were not exploited in the proper way and hence no doubt the conclusion follows that the deposit of petroleum, in the Kuban Province is characterized by experts as possessing specific pecularities with which, everyone who contemplates boring for petroleum there, must take account. That is why the English companies which desire chiefly to turn their attention to speculation on the Bourse and only partly, so to speak, among other things to deal energetically with work on the spot were early consigned, if not to destruction, at all events to heavy loss, and this fact no doubt influenced the disposition generally of English capital in Russian business.

It should be noted that Kuban oil compared with other petroleum is distinguished by a high content of benzine, a point which, thanks to the development of motoring and aviation, grows in importance day by day. The Kuban petroliferous region will serve for the export of petroleum products from Russia but not by any means for the flooding of the Russian market with petroleum products, and this circumstance should be remembered by the Baku and Grozny petroleum firms which, as it is alleged, have just secured allotments at Kuban, but do not contemplate the development for fear of future competition. Such a view cannot under any circumstances be considered correct, and on the contrary it would appear to Russian petroleum firms acquainted with local conditions that they should be at the head of those enterprises which either have already begun serious work in the production of petroleum at Kuban or contemplate doing so.

In the Government town of Ekaterinodar, applications for claim certificates are being made every day and the administration is quite unable to grappel with them all. One reason is a shortage of employees in the mining office and there is also a lack of hands for marking off allotments, the issue of which takes months instead of days which would be the normal period, and cases are cited in which agreements respecting these take over a year in preparation. As a consequence much money is being sunk in machinery and tools besides wages, and for want of a solid agreement petroleum production is delayed. A considerable number of allotment holders, representing 400 sections in all, have specially petitioned the Government to have this unsatisfactory state of affairs put straight. To anticipate the decision of such questions of principle is not my province here, but I must observe that the promptest solution of them as well as the promptest possible reply to various kinds of documents that reach the Government appears of primary and essential importance for the petroleum industry that is to develop in Kuban.

Exact statistics of the petroleum output up to December 1, 1909, give a total of 449,580,000 poods (poods = 36 lb.), as compared with 433,180,000 poods for the corresponding period of 1908, making an increase of 16,400,000 poods of raw oil for the 11 months, which is to be attributed exclusively to developments in the Bibi-Eybat district. In all the other districts the output has receded.

NEW YORK

Silver Price Advancing.—New Enterprise in Mexico.—Expensive Litigation in Mexico. — Western Mining Shares on New York Stock Exchange.—The Coppers.—Utah Copper's Great Output.—Hill Wants Lower Copper.

The improving price of silver is the bright spot in mining circles in the East. Boston is primarily a copper centre, especially of the Lake producers. These have suffered with other copper shares. The development companies opening Mexican properties and the shareholders in such enterprises are most largely interested in the growing demand for silver. A 55c. silver market will mean much for many Mexican mines. The development of the immense low-grade orebodies of the Mexican mines appeal to the average Eastern investor more strongly than the continual prospecting for new veins in Cobalt. A further advance in silver will mean profit for many mines which have been just paying expenses. The interest in Mexico is growing throughout the East, although the promotion of new enterprises is almost at a standstill. One of the most recent of important organizations formed to exploit Mexican mining properties is the Mexico-Orient Mining Syndicate, a development company formed by Arthur E. Stillwell. The new development company is to operate in Chihuahua and Sinaloa, along the line of the new road. English capital has been enlisted, and the Mining Syndicate has been organized as an English corporation with a capital of £125,250.

Samuel Untermeyer, of the New York bar, who is credited with having received a fee of $800,000 for effecting the Utah Copper-Boston Consolidated merger, will have to look to his laurels. In a recent decision by the courts of Mexico City, in a suit brought by the Mine Development Co. against George D. Barron, president of the company, and also president of the Tezuitlan Copper Mining & Smelting Co., the attorney for plaintiff was awarded a fee of ₱2,302,500, which overtops Mr. Untermeyer's last triumph. Mr. Untermeyer has in hand the merger of the La Rose, Nipissing, and Kerr Lake of Cobalt, and in this deal will lie his opportunity of going once more to the head of his class. The judgment against Mr. Barron involves the sale by Barron of the properties now operated by the Tezuitlan Copper Mining & Smelting Co., for $11,529,542, so that the enormous fee awarded was in reality about 10% of the judgment. New suits based upon the finding will probably be brought against the present Tezuitlan Copper Co., the Mexican corporation.

The successful development of the rich orebodies of the Tuolumne Copper Co., at Butte, has been carried forward under constant possibility of legal complications with the North Butte Copper Co. The matter finally culminated in a suit started by the North Butte which at the outset prayed to enjoin the Tuolumne company from further work. The request for an injunction was finally withdrawn and a quieting of title in a fractional claim and an accounting asked for. This will give both sides a chance to be heard.

One of the whimsicalities of the sentiment which rules the market is the failure of the rise in silver to add in the least to the activity of the Cobalt market. As a mining camp Cobalt is busier than ever; the rise in silver has meant a large increase in the profits from Cobalt properties, but the public has ignored this phase of the situation. Many of the pioneers in Cobalt have gone to Porcupine. Recently D. Lorne McGibbon, president of the La Rose, and a member of the Nipissing board, has become interested in Porcupine, as a member of a syndicate taking over a group of seventeen claims, known as the Doble property. The purchase of a controlling interest in Nevada Hills by a syndicate, headed by H. C. Frick, of Pittsburg, and J. H. Carstairs, of Philadelphia, is taken to signify that the mine has been developed into a property of greater promise than the public had been led to believe, and also that Nevada Hills will become the leader of the Nevada precious metal share market which with Goldfield Consolidated is transferred to the New York Stock Exchange. It is true that in a sense the listing of mining stocks upon the New York Stock Exchange is a recognition of standing, but in every

instance market activity in the various stocks has soon langulshed. Until the New York Stock Exchange changes its attitude toward mining investments, such issues as procure admission there, will continue to find themselves in a hostile atmosphere. Goldfield Consolidated has enjoyed strong support and an active market on the curb assisted by arbitrage business between New York, Goldfield, and San Francisco. The arbitragers will cease to trade when the shares leave the curb, and like Nevada Consolidated, Goldfield Consolidated will soon have a market of but a few shares daily. Tonopah is making a strong bid also for a revival of interest due to development in the Tonopah-Belmont. A report to the directors at the July meeting is expected to show that net profits for June exceeded $100,000. Ely Consolidated, recently boomed to above $1 per share, has levied an assessment of 5 cents per share. The company naively states that money is needed for salaries and development work. It is only a few months since announcements were made in the press that the property had been proved a big mine. The assessment has caused a market shrinkage of about 80%. The annual meeting of the Silver Mines Exploration Co. was held in New York this week. This is the Lewisohn organization which handles operations in Kerr Lake, Wettlaufer, and other Canadian properties, and will probably be the holding company through which the San Cayetano at Guanajuato will be developed.

The copper situation remains unchanged, the only matter of importance being the market shrinkage of Amalgamated. An issue paying but 2% could hardly be expected to hold its own in a falling market and the anomalous position occupied by Amalgamated has been a matter of comment for some time. Under heavy selling the stock sold off to 57 and students of the copper market consider it still too high. The Granby has started three diamond drills to prospect a part of the company's unexplored territory. Officers of the Granby maintain their reticence, and shareholders are without official information regarding property conditions. At the annual meeting in October, a statement is expected, and it is rumored also that resignations of J. Langeloth, president, and B. Hochschild, vice-president, will be tendered. Lake Copper, another Boston issue, which enjoyed much notice about the first of the year, and sold up to 94½, has been causing shareholders much uneasiness by its market shrinkage, 32 having been reached during the past few days. The slump is attributed to a falling off in value of the ore. Present milling operations show the ore to run 21 lb. copper per ton. The Raven Copper Co., also a Boston copper, has levied an assessment of 10c. per share. F. Augustus Heinze, now in Europe, in an endeavor to sell the $750,000 of bonds of the Ohio Copper Co., has evidently found it uphill work. He states that the timber lands of the United Copper Co., in British Columbia, will probably be sold to English capitalists; this will put the United Copper Co. in position to take the Ohio bonds and advance the money needed. While assessments are falling about the ears of shareholders, and the copper surplus is increasing, and James J. Hill is advising the selling agencies to make a price that will put the high-cost coppers out of the running, the situation has some good features. The Canadian Pacific is to string 2400 miles of copper wire between Montreal and Vancouver. It would not take many such orders to ease the burden of the copper surplus. The Ortega Mining Co., of Cananea, is being once more reorganized. The Ortega, the Miller Mining Co., the Corregidor, the Red Cloud, the Chapultepec, and the Cia. Minera Cuño de Plata, most of which properties were formerly a part of the Southwestern Mining Co., and later organized into the Kansas Cananea Copper Co., are being reorganized into the Arizona-Cananea Mines Corporation. The properties aggregate 4202 acres, part of the ground adjoining the Greene-Cananea. The mine management is to be in the hands of John T. Morrow, formerly general manager of the Greene Consolidated. There has been $400,000 expended in the development of the properties. The present management plans to open the ground for a production of 2000 tons per day, and erect a plant like Greene-Cananea to handle this output. Copper costs are estimated at 9c. The new interests in Nevada Hills have plans under way for the erection of a 100-ton mill, including the foundation for a second section of like capacity.

TORONTO, CANADA

Cobalt Shipments.—Gowganda, Porcupine, and Great Pike Lake.—Iron Ore in Quebec.

The physical condition of Cobalt was never better. The output has lately been well maintained and numerous good finds have been made. A record bullion shipment was made on July 12, including the initial consignment from the new cyanide plant of the Nova Scotia of 26 bars, and 35 bars from the O'Brien. The two lots contained 60,200 oz. pure silver. The Hudson Bay will put up the fourteenth concentrating mill of the camp, which will have 20 stamps and a capacity of about 80 tons of ore per day. The Crown Reserve has issued a statement for the first six months of 1910 showing shipments valued at $709,569, operating expenses $109,644, and royalty $63,861, leaving profits of $536,064, of which $530,644 has been paid in dividends. At the Little Nipissing the winze on No. 2 vein has been sunk to a depth of 75 ft. from the east drift on the 155-ft. level and will be put down 50 ft. farther. At the present bottom of the winze No. 2 and 4 veins unite forming a large and rich orebody. On the Cobalt Lake property some fine showings occur in the north drift from the west cross-cut at the 280-ft. level. The vein, about 3 in. wide at this point, contains an important amount of silver. The Wyandoh, in the Gillies Limit, recently made its first shipment, comprising 24 tons, over half of which was high grade. A new vein was lately uncovered south of No. 1 and cross-cutting is in progress to reach this and several other veins, which show well on the surface at depth. The Rochester has sent a 10-ton shipment of ore taken from a new vein on the 75-ft. level, to the new sampling plant of Campbell & Deyell at Cobalt. A new and rich vein has been found in the Lawson property of the La Rose Consolidated on the west corner of the lot. Surface development on the Nipissing has resulted in the discovery of a 4-in. calcite vein, which will probably run high grade, and has been traced for 30 feet.

The Millerett, Gowganda district, has been a steady shipper for some months, having sent away 283 tons this year to date. The control of the Bartlett mine in the same district has passed into the hands of a syndicate headed by J. R. Carter, and operations are to be resumed at an early date.

The funds will be raised by the sale of 300,000 shares of treasury stock, which will be taken up by the large holders at 25c. per share. The main shaft is down 150 ft., but the vein has dipped away from the shaft and driving will have to be done to reach it. In South Lorrain the Keeley has cut a 12-in. vein of smaltite and native silver on the 100-ft. level. The Kittie near Loon lake, operated by the Howard Syndicate, has struck a vein 7 ft. below the surface carrying 300 oz. silver. The Montreal Reduction & Smelting Co., which built a smelter at Trout Mills near North Bay for the treatment of Cobalt ores, is in process of liquidation, and the plant which cost $275,000 and was never operated, is offered for sale. Many prospectors have gone to the country around Great Pike lake, situated about 40 miles southwest of Porcupine, the trail from that point leading down the Matagami river. The rocks in this area are granite and schist, and gold has been found in quartz veins and stringers at the contact of these rocks.

Samples brought to Porcupine show free gold. D. Lorne McGibbon, president of the La Rose Consolidated, and Frank Armstrong, have taken over the Bruce claims in Porcupine comprising 17 locations. The Mines Branch of the Canadian Department of Mines has drawn attention to the existence of an iron orefield 90,000 sq. ft. in area, about 4½ miles from Chat's falls, Pontiac county, Quebec, which was practically unknown. The ore is reported as being suitable for concentration for iron manufacture by either electric or blast-furnace.

Sinking has been discontinued at the 1300-ft. level of the Briggs shaft and a station is being cut at that point.——A gasoline hoist has been installed at the White Tail Deer shaft of the Copper Queen Consolidated Mining Co. and sinking continued at a depth of 45 ft.——John Korp and associates, operating a lease on the Wolverine, shipped a carload of lead-silver ore to the El Paso smelter.

GILA COUNTY

(Special Correspondence).—The first two churn-drill holes sunk on the property of the Cactus Copper Co., several hundred feet northeast of the Hamilton shaft where nearly all the development has been done, met heavy flows of water but no copper-bearing schist. These holes were not put down in the expectation of finding ore, but for the purpose of proving that no ore underlies this part of the property, where the main working shaft will be sunk in the near future. The first hole attained a depth of about 500 ft. and the second hole was abandoned about 260 ft. from the surface. The drill is now working in the bed of Pinto creek, about 600 ft. southeast of the Hamilton shaft.——A Sullivan 2¼-in. diamond-drill on the 650-ft. level of the Superior & Globe mine has been in operation in diabase for the last two days.——Construction on the surface plant of the Miami Copper Co. is making rapid progress under the direction of H. Kenyon Burch. The old shaft-house at shaft No. 4 has been torn down and a new one is to take its place. The two Nordberg hoists, one for the man-cage, the other for ore hoisting, are on the ground ready for installation. A raise is now being put up on churn-drill hole No. 6.——The churn-drill at work at the Warrior is now developing the Dadeville claim and is at a depth of 475 ft. in schist.——The diamond-drill formerly in use at the property of the Superior & Boston Copper Co. is now being employed underground on the seventh level of the Arizona Commercial mine.

Globe, July 15.

MOHAVE COUNTY

C. E. Price has secured a bond on the Kimball group on Bill Williams fork and put a force of men on development work.——Development on the 100-ft. level of the Golconda opened a shoot of rich ore at a point in the vein that was thought to be barren.——A crew of the Needles Smelting & Refining Co.'s engineers is making a preliminary survey for a branch track from the end of the line at Chloride to the Tennessee mine which the company is working under lease and bond.——The Tracy Engineering Co. is to add another unit to the power plant at Kingman, increasing the capacity 50%. There has been a constantly increasing demand in the district for electric power and the company will probably add four more units within a short time.——The Frisco Mining & Development Co. has installed an automobile truck to carry freight to the mine.——A new hoist and pumping plant has been ordered for the I. X. L. mine near Stockton hill.

YAVAPAI COUNTY

The Tip Top Heath Mining Co. which is opening the old Tip Top mine in the southern part of the county to obtain the tungsten ore that was left in the mine by the former operators, has cut a body of silver ore, samples from which assayed 1000 oz. silver per ton.——The Jerome-Verde Copper Co. has completed the installation of the new machinery and will unwater the shaft.

YUMA COUNTY

The churn-drill operating on the Planet property cut a body of native copper at a depth of 535 ft.——Rich samples of copper ore have been taken recently from the drift on the 40-ft. level of the Sweeney group in the Turtle mountains.——A churn-drill has been taken to the Horn property near Grammett on the Parker cut-off and will soon be started to prospect the ground.——W. E. Scott who is operating the Goodman mine in the Quartzsite district is treating the high-grade ore in the small stamp-mill on the claims and is planning to erect a larger plant in the near future. There is 18 in. of high-grade material and about three feet of ore that will assay $7 to $10 per ton.——The Interstate Gold Dredging Co. has enlarged its plant to bring the capacity of the rest of the plant up to that of the steam-shovel.

CALIFORNIA

INYO COUNTY

A 4-drill compressor has been hauled to the Casa Diablo mine and is now being installed. The shaft is 310 ft. deep and will be continued to the 400-ft. point where a station will be cut and lateral work started on the vein. The company shipped a $3000 gold bar about the first of the month.——F. B. Remington, Samuel Musser, and William Cahoone have shipped a cyanide plant to Benton and will install it at the Edwards ranch, which they secured some time ago. It is estimated that there is 15,000 tons of tailing from the old Commache mill on this ground from which assays as high as $14 per ton have been obtained.

MARIPOSA COUNTY

William Dusel has opened a shoot of $150 ore on one of the claims in the old Teats group at Whitlock which the Dusel brothers secured some time ago. Over 2000 ft. of development has been done since the mines were acquired and the operators now have 60 tons of high-grade ore on the dump.

NEVADA COUNTY

J. E. Wise and E. Edwards are to incorporate a company to operate the Richmond and Gold Line claims near Moores Flat in which they are interested.

PLACER COUNTY

The drift at the Big Dipper near Iowa Hill has opened a rich bed of gravel and the force at the mine has been increased to 50 men.——Work at the Dewey which has been suspended for some time on account of the lack of pipe, has been resumed.——R. H. Young has resumed work at the Annie Laurie mine and will develop the shoot that was opened in the shaft two years ago.——Six men are working in the adit at the Good Friday mine at Ophir, and a vein of fair ore has been opened.

SHASTA COUNTY

F. H. Dakin, Sr., president of the Virginia Gold Mining Co., has commenced work at the Uncle Sam mine back of Kennett following the surrender of the option on that property which was held by the Hazel Gold Mining Co.——The smelter town of Winthrop was destroyed by fire though the smelter which is situated a short distance from the town was uninjured. The loss is estimated between $75,000 and $100,000 of which about two-thirds was covered by insurance. Though the smelter of the Bully Hill Mining & Smelting Co. was shut down the first of the month, work has been continued in the mines of the company and a small amount of ore shipped to the Coram smelter.

SIERRA COUNTY

Work has been resumed at the Sixteen-to-One mine in the Alleghany district which has been shut down for the past few months on account of litigation. H. L. Johnson, owner of the Tightner, will be manager for the reorganized company.——Work is to be started at the Runyan group in Hungry Mouth ravine.——The boilers at the Bear Creek mine near American hill have been fired up as the water supply has become too low to operate the two-stamp mill.——The contractors who are driving the adit at the White Bear to drain the lower end of the Monte Cristo property

are reported to be making good headway although the rock is quite hard.——The shaft of the Poker Flat Mining Co. is down 275 ft. and has 40 ft. farther to go before the gravel is opened.

SISKIYOU COUNTY

The Yellow Rose mine situated near the border of Siskiyou and Trinity counties will resume development this fall. All work will be done from the lowest adit which is in 1200 ft. and 650 ft. below the apex of the vein. It is the intention to drive a 340-ft. raise to connect with a winze that was sunk on the ore some time ago.——The Wellman dredge is running steadily at McConnell Bar and the clean-ups are said to be satisfactory.——The Van Brunt mine is running two shifts but will shut down for the season in a short time. ——Operations are to be resumed at the Frazier-Gibson mine below Happy Camp as soon as the fall rains commence.

TRINITY COUNTY

The lining of the tunnel of the Trinity River Mining Co. near Lewiston collapsed and work has again been temporarily suspended. This is the third time the company has been on the verge of starting only to be set back by some accident.——Work has been resumed at the Golden Jubilee mine near Carrville which has been idle for a long time.—— After a long period of inactivity the Wagner has resumed operations and the management is meeting with good success. The drift which is being driven on the vein has opened a shoot that assays in the neighborhood of $70 per ton.——At the Dorleska the mill is running on ore from the dump and development is being carried forward in the mine.——The Poverty Slide hydraulic mine at Trinity Center, has been shut down for the season on account of the lack of water.——The Van Ness is sinking a shaft from the adit-level to explore the vein.——The Blue Jay mill which is equipped with a concentrator, crusher, and Pelton wheels to furnish power will be started in a few days.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—A streak of ore 10 in. wide has been uncovered in the west drift of the fourth level of the Smuggler mine on Brown mountain. From a shipment of 10 tons made last week a return of $110 to the ton in silver and lead was realized. The shaft is to be sunk another 225 ft., levels to be started from each 75-ft. station. ——Shipments of ore have been started from the True Fissure property, the product being sent to the Golden pyritic smelter. The ore is being taken from the west drift of level No. 6. Willis Bristol is manager.——The foundations for the 100-ton mill at the Conqueror mine have been completed and a force of carpenters has been put to work constructing the building. Machinery has been ordered and will arrive the latter part of this month. W. S. Pryor is manager.——The Ophir Mountain Mining Co. has taken a lease and bond on the Kentuck mine on Bellevue mountain. Operations will be carried on through the Central adit.——A compressor plant has just been placed in position at the Blue Bell property on Seaton mountain. Development is in progress and ore is being broken to supply the new 50-ton mill.——Shipments have been started from the Cumberland property at Alice, the product being sent to the Golden smelter. A carload of ore was shipped last week from the Princess Alice mine to the Golden smelter.

Georgetown, July 16.

GILPIN COUNTY

(Special Correspondance).—Work has been started in the construction of a 25-ton mill at the property of the Golden Sun Mining & Milling Co. J. L. Gordon, the manager, states that dynamos have been ordered and that the adit workings will be electrified.——It is understood that the International property on South Boulder creek is to be equipped with a 25-ton milling plant.——A 6-in. streak of smelting ore has been uncovered on the Grace property that is worth $32.80 per ton in gold and silver. The property is situated in Russell district and is a new prospect. ——Heavy shipments are being made from the Smuggler property. All of the product is being treated at the company mill. G. M. Ashmore is manager.

Central City, July 15.

LAKE COUNTY

The amount of work at present being carried on in the Leadville gold belt district surpasses that of any previous year, and is not being confined to where the known ore-shoots exist, but is being carried into new territory toward Mosquito range and Prospect mountain. Since the opening of the summer season three new shafts have been started in this part of the district, the Little Mary, Famous, and Fourth of July. The two former are situated in Big Evans amphitheatre and are close to the Dolly R., both claims having been unwatered by the Yak tunnel.——The owners of the St. Louis mine have secured a lease on a 750-ft. block of ground on the north end of the Fanny Rawlings mine, and at present are retimbering and putting the shaft in good order. The property has been unwatered, and when the repair work is completed operations will be started.——Good progress is being made in driving the Alps-Aztec adit toward the head of Little South Evans gulch. The breast is now in 530 ft., but the operators have several hundred feet yet to drive before the objective point is reached. While driving the adit numerous small veins have been cut.

OURAY COUNTY

H. P. Foley while driving a cross-cut from the shaft of the Carbonate Queen property near Ironton cut a 12-in. seam of galena ore that assayed 40% lead and from 60 to 100 oz. silver per ton.——It is reported that operations are to be resumed at the Savage Bear in the Bear Creek district at an early date.——J. P. Lang is shipping high-grade copper-silver ore from the Morning Star property.

SAN JUAN COUNTY

The eastern gold belt of San Juan county is again to the front with a find of exceptional value in the Tiger mine, level D. The Iowa Tiger is leased to the Iowa Tiger Leasing Co., made up of local merchants and mining men. For the past 18 months they have been mining a lead ore without any knowledge of the rich gold along side of it. It was noted that by throwing more ore into the mine run from the Tiger, the gold value in the concentrate ran up to one or two ounces per ton. The reason for this was shrouded with mystery until very recently, when prospecting the hanging wall disclosed minute stringers of what appeared to be iron pyrite in the candle light. On bringing this to the surface, however, it was found to be free gold. At lot of 2800 lb. has been shipped to Silverton, the first assay of which ran 62 oz. in gold. The extent of this occurrence is not known as the stope is filled with ore below and not mined out above. This is a repetition of the discovery in the Camp Bird mine where the galena was thought to be the pay-streak and Thomas Walsh afterward found the gold value in the hanging wall. It is reported that Louis Quanstrom, foreman of the mill, is the one to have made the discovery.

SUMMIT COUNTY

The lessees of the Jumbo mine in the Breckenridge district, have got the property in good order and are opening several shoots of free-milling ore.——The aerial tram at the Arctic has been completed and the mill will be started in a few days.——Money has been raised to build a large mill to treat the ores from the Peruvian and Shoe Basin mines and construction will soon be under way.——The Rothschild is expected to resume work in the adit shortly.

TELLER COUNTY

The compressor from the Golden Wedge mine in the Cripple Creek district has been moved to the Dollie Varden by the lessees.——J. T. Keller and associates operating a lease in the Callie mine have opened the extension of the Hodges vein and are shipping ore that assays as high as five ounces in gold per ton.——The Vindicator Mining Co. will pay a dividend of three cents per share on July 25 which will total $45,000.——The Cresson has completed the installation of the big first-motion hoist and resumed work. ——Sub-lessees operating on the eighth level of the Mabel

M. claim have opened a shoot of $100 ore.——A churn-drill has been set up at the shaft of the El Paso mine and a hole will be drilled from the bottom of the shaft to the tunnel level.——Jerry Jones and associates who have leases on the 700 and 300-ft. levels of the Strattons Independence have cut two shoots of ore and are now shipping high-grade material.——Lessees on the American Eagle's property shipped 25 tons of ore that assayed seven ounces gold per ton.——The first clean-up of the new Portland mill resulted in a $9000 gold bar. The directors of the company paid a dividend of two cents per share July 15 which amounted to $60,000.

IDAHO

IDAHO COUNTY

Machinery for a 20-stamp mill to be erected at the Comstock mine near Dixie is being hauled to the property and a site for the foundation is being graded. The stamps weigh 1500 lb. and when the mill is completed it will be one of the best equipped in the State.——The adit at the group of William Simpson has reached the hanging wall of the vein exposing 25 ft. of copper ore.——The 10-stamp mill at the Idaho Champion mine on Crooked river has been started and it is reported that the company is now amply financed to carry on the development of the property.

NEZ PERCE COUNTY

The Idaho company began work May 15 with its new dredge at Pierce, and it is operating successfully and handling 2000 cu. yd. per day of material that runs 20c. per yard. This company has 150 acres of dredgable ground which is estimated to be 8 years' work. The dredge has 3¾-cu. ft. buckets, close connected, and was built by the New York Engineering Co. M. H. Hare of Spokane has taken a 20-year lease on the Idaho company's 120 acres of placer ground at the junction of Oro Fino and Rhodes creeks, close to Pierce, the lease including that company's Risdon dredge, which has 3¼-cu. ft. buckets, open connected. This ground has an average depth of 12½ ft. and will run 11 to 18c. per yard. The dredge is in operation.

MONTANA

BROADWATER COUNTY

Hampton & Easterly have opened a shoot of high-grade ore in their shaft at a depth of 35 ft. The group is in the Radersburg district, and the claims cover a contact between granite and limestone.——The Little Giant property, west of Radersburg, is being systematically developed from an adit that is being driven to tap the vein at a vertical depth of 400 feet.

DEERLODGE COUNTY

The sale of the Southern Cross mine which has been pending for some time, has fallen through as the principals have been unable to agree on the value of the mine.

NEVADA

ESMERALDA COUNTY

(Special Correspondence).—The proposition to merge the Rawhide Coalition and Queen properties is being well received by stockholders, and it is possible that such a consolidation will be shortly arranged. The officials of the two companies plan the erection of a company mill as soon as the consolidation has been perfected.——The St. Ives' lease on Queen is developing the sulphide ore recently opened on the 400-ft. level. A cross-cut is being run from the 200-ft. level to open the property toward the Grutt-Balloon Hill lease.——The Victor lease is arranging for the deepening of the shaft to the 400-ft. point and the driving of laterals on this level. The last mill-run yielded 476 oz. of bullion, valued at $2700.——The Mint lease on Coalition has arranged for the treatment of about 600 tons of ore at the Klinker mill. A recent test disclosed an approximate recovery value of $12 per ton.——The Grutt-Balloon Hill lease is steadily shipping ore to the Hazen sampler, two large ore-wagons being engaged in the work.

Rawhide, July 16.

HUMBOLDT COUNTY

(Special Correspondence).—The camp of National is recording increasing activity and the shipment of bullion from the National Mining properties is growing steadily. In June the camp produced $250,000 in bullion, and low-grade ore to the approximate value of $150,000. The first bullion shipment for July amounted to $51,000. The ore is treated in two old pan-arrastre mills, one operated by the National Mining Co. of Nevada, the other by the Stall brothers.——The Florence Leasing Co. has secured an agreement with the Seven Troughs Mining Co. whereby it will be permitted to run a drift from the bottom of the main 750-ft. shaft to connect with the lease workings.——The Seven Troughs Mining Co. is to sink its shaft to the 1000-ft. level.——The Tyler lease on Seven Troughs Coalition has intersected the Wihuja vein in the shaft at a vertical depth of 422 feet.

Winnemucca, July 15.

WHITE PINE COUNTY

(Special Correspondence).—An air-compressor drilling plant has been ordered for the Clipper shaft of the Ely Central company. The company has also ordered two traction No. 23 Star drills, which will be used in exploiting new territory. The Eureka shaft is now down 560 ft., the drift along the fault plane 40 ft., and the south cross-cut 70 ft. The cross-cut is striking stringers of rich sulphide ore, containing from 10 to 30% copper. Twenty-five men are engaged in the erection of the 10-stamp mill of the Nevada Amalgamated at Willow Patch, in the eastern portion of this county. It is expected that the plant will be completed and the stamps dropping in about 60 days.——Robert Plate arrived last night from an overland trip from Goldfield to Ely. The trip was made for the purpose of securing data as to the probable tonnage of ore along the line of the proposed road. Mr. Plate spent about six weeks on the trip and thoroughly investigated all of the camps along the line of the road. He was particularly impressed with the tremendous showing of ore at Tybo, where development has been carried on for the past four years with a considerable force of men. It is understood that the tonnage of the 2G mine alone would justify the building of the line, it having been estimated that the property could load a train of cars every day for two years from ores already in sight and on the dumps.——Material for the completion of the fifth furnace at the Steptoe smelter is now on the ground, the waste-heat boilers used in connection with the furnace have been bricked in and are being connected. It is expected that the furnace will be completed during the present year. It is greatly needed. The full eight sections of the concentrator are in operation, and about 9000 tons of ore per day are being treated. The hydro-electric pumping plant in Steptee valley near the old McGill ranch is being used when necessary as an auxiliary source of water-supply for the mill. It has a capacity of 10 second-feet, but the supply varies as it is only used when occasion demands. The new tailing sampler is completed and in operation. It was erected for the purpose of sampling the general run of all tailing. All sampling is done automatically by a system of hydraulic and electric devices.

Ely, July 16.

WASHINGTON

FERRY COUNTY

(Special Correspondence).—The Hess Cyanide System Co., of Spokane, has the contract to erect for the Pacific Ore Co. at Republic, an ore-crushing and cyanide plant of 120 tons per day capacity, which is to be operated on custom ore of that district. The crushing will be done with a jaw crusher and a Chilean mill, supplied by the Hallidie company. The pulp will then be cyanided in Hess agitation and aeration tanks. It is stated that 150 tests have been made on Republic ores by the Hess method, and that the results showed an extraction of 98½% of the assay value of the gold in the ore. The Chilean mill is to pulverize the ore in cyanide solution.——The Kettle River Mining Co., which has a partly developed lead-silver property four miles

from Orient, has ordered a concentrating mill of 50 tons capacity. The plant is equipped with a crusher, rolls, jigs, tables, and vanners. E. W. Scothorn, manager, states that the mine is opened by a 200-ft. vertical shaft, over which is a steam-hoist.——The Republic Mines Corporation has paid a total of $25,000 in dividends to date, and it is announced that the directors will now declare a regular monthly dividend.

Republic, July 16.

KING COUNTY

(Special Correspondence).—The Seattle Cascade Mining Co., which has developed a copper mine four miles from Berlin, has arranged to build a concentrating plant of 100 tons per day capacity, and it intends to have the mill complete by October 1. The ore dressing will be done by a crusher and Chilean mill, and the concentration by Wilfley tables. F. G. Winquist of Seattle, is one of those interested, and Robert Dixon is superintendent.

Berlin, July 18.

KITSAP COUNTY

(Special Correspondence).—The Tripple Trip Mining & Milling Co. is developing by means of shafts, adits, and open-cuts, its group of claims in the Olympic range, 80 miles from Seattle, near the head of Hood's canal. The property is 8 miles from tidewater and 3½ miles from a railroad. It is stated that the mineral zone, in slate and greenstone, contains six veins of manganese ore, tests of samples assaying 55.17% manganese, 0.17% sulphur, 0.11% phosphorus, and 18.62% silica. G. W. Morley and associates are in control.

Seattle, July 18.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—An amalgamation involving 11 claims in the Sheep Creek district was put through last week, the La Rose and Gold Belt groups being placed under one management. The claims were owned before the amalgamation by Edward Peters, of Ymir, W. Kennedy, of Salmo, and associates.——The second payment under the bond on the Echo-Sunrise group in the Bayonne district, has been made by the Mercantile Trust Co., Vancouver. At present R. Dalby Morkill is in charge of development work at the property.——A company known as the West Kootenay Mining Corporation, Ltd., has taken hold of the Joker gold milling property and is installing a new plant and 10-stamp mill.——A cross-cut is being driven on the downward continuation of the recent rich finds in the Rambler-Cariboo from the tenth level.——The True Fissure Mining & Milling Co., N. W. Emmens, engineer, Trout Lake city, has decided to put a tramway in from the mine to the city. The surveys have been completed by Mr. Emmens. Ten carloads of ore averaged $60 per ton. The principal ore-shoot contains galena and gray copper and averages 6 ft. in width. Cincinnati capitalists are behind the company. ——Plans are about completed for the erection of a stamp-mill at the mine of the Aurora Mining & Milling Co., Moyie. H. Dimock is the superintendent.——A deposit of asbestos, about 56 inches in width, has been located near Okanogan falls.——The Red Cliff Mining Co. is planning to build a smelter to complete its mining equipment. The company is having surveys made and will very likely develop 450 horse-power in Lydden creek.

Rossland, July 16.

MEXICO

CHIHUAHUA

The output of the Rio Plata mine, in the Arteaga district, last month was 55,779 oz. of silver; 946 tons of ore were treated, and 68 bars, containing 70,000 oz. of silver, have been shipped to the city of Chihuahua since July 1.

JALISCO

The power lines of the Chapala Hydro-Electric-Irrigation Co. is now fast nearing the El Favor mine, and the substation for distribution of power to the entire Hostotipaquillo district is under construction on the company's ground.

SONORA

The Washington copper mine in the Arizpe district which has been under bond to James Douglas and L. D. Ricketts, has reverted to the original owners, F. O. Bostwick and A. R. Dickson. The bond was effective for eight months and during that time $76,000 was spent by the operators, $35,000 of which went as payments to Bostwick and Dickson.——A new cyanide plant is being installed at the El Tigre mine. ——The West Coast Copper Smelting & Refining Co., operating in the southern portion of the State, has purchased machinery for the erection of a smelter, and expects to have the plant completed within a year.——The Sonora Central Mines Co., operating the Santo Domingo property in the vicinity of Alamos, is erecting a concentrating mill that will have a capacity of 100 tons per day.——The Sonora Copper Co. has graded the site for the 100-ton smelter to be erected at the property a mile and a half east of Noria and the machinery has been shipped to the mine.

El Favor Mill, Hostotipaquillo District.

PHILIPPINE ISLANDS

The Headquarters Mining Co. has completed an automobile-road from the property to the Antimok road, a distance of one and a half miles, and is preparing for the installation of a 10-stamp mill. The plant will include a cyanide annex equipped with Ridgway filters.——Several groups of placer claims in the Nueva Ecija district have been tested and proved satisfactory. Negotiations are under way for the installation of dredges and it is believed that at an early date several large contracts will be concluded that will be of great importance to the general development of that district.——The San Mauricio has added several classifiers to its plant.——The Philippine Exploration Co. has secured an option on the property of the Syndicate Mining Co. in Masbate. The option provides for extensive development of the ground.——The dredge of the Philippine Gold Dredging Co. has been moved to the Malaguit river.——The dredge of the Stanley Dredging Co. has cut through the ridge in which it has been working and is now in the rich bottom ground.——A 30-ft. vein of ore assaying $6 to $7 with a streak on one of the walls that assays $40 per ton, has been opened on the Antamok Valley Mining Co.'s property.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

F. W. Bradley is in Alaska.

J. R. Finlay is in San Francisco.

Ralph Arnold was in San Francisco.

J. R. Farrell is at Auburn, California.

Capt. Murdoch Wiley is in a hospital at Seattle.

Francis Drake is in the hospital at San Francisco with typhoid, but is doing nicely.

Reiji Kanda was in San Francisco this week on his way from London to Tokyo.

J. D. Hubbard has been visiting mines in Trinity county, California.

T. Lane Carter, of Chicago, is in the West, and is expected in California.

H. W. Hardinge, of New York, has left for Sweden on professional business.

R. B. Lamb is at El Dorado, California, having just come from Radersburg, Montana.

Allen M. Yonge has joined J. R. Farrell and R. C. Shaw in general engineering practice.

Leonard D. Sivyer, of Los Angeles, has been examining mines in New Mexico, Arizona, and Nevada.

Homes Wilson, manager of the Keane-Wonder mine in Death Valley, California, is in San Francisco.

William C. Russell, manager of the Rawley mine at Bonanza, Colorado, is in New York on business.

Algernon Del Mar went north this week as manager for the Fort Bidwell Con. M. Co. at Fort Bidwell, California.

F. A. Horswill, superintendent of the Stone Cañon coal mines, Monterey county, California, is in San Francisco.

J. V. N. Dorr and family are spending the summer in the East. Mr. Dorr's temporary address is 85 Front street, New York City.

F. C. Brown has resigned as general manager for the Waihi Grand Junction and Komata Reef mines of New Zealand and is at Boise, Idaho.

B. R. Bates has left San Jose de Gracia, Sinaloa, Mexico, to take charge of the development work for the Gold & Silver Recovery Co. at Guadalupe.

Ehle V. Daveler, recently with the Utah Copper Co. at Garfield, is superintendent for the Phoenix Gold Quartz Mining Co., at Sierra City, California.

OBITUARY

Charles A. White, who died at Washington, D. C., June 29, in his eighty-fifth year, was one of the pioneer geologists of America. He was born at North Dighton, Mass., and educated as a physician, as were many of the early American scientists, the medical schools being the only places at which professional scientific training could then be obtained. While practising at Burlington, Iowa, the young physician began collecting and studying the fossils that are there so abundant. In 1866 he succeeded in getting the Iowa Geological Survey re-established, and while in charge of it from 1866 to 1870, did much to promote the development of that State. In later years he served as professor of Natural History at Iowa State University and at Bowdoin College, and as geologist and paleontologist in connection with the 'Powell', 'Hayden', and United States Geological Surveys. From 1879 on he was connected with the United States Museum. While his major scientific contributions relate to the paleontology and stratigraphy of the Cretaceous, it should not be forgotten that his earlier work on coal was of direct and significant economic import. Dr. White was a charming man who contributed to his profession not only by his personal work, but also by inspiring and helping the younger men who were his associates and successors.

Recent Publications

Re-Survey of the Maryland-Pennsylvania Boundary, Part of the Mason and Dixon Line. Maryland Geol. Surv., Vol. VII. Pp. 412, ill., map, index. Baltimore, 1908.

Coal Fields of Northwestern Colorado and Northeastern Utah. By Hoyt S. Gale. U. S. Geol. Surv., Bull. 415. Pp. 265, ill. maps, index. Washington, 1910. This is an excellent account of important coalfields and a good example of high-class geological work.

Occurrence of Arsenic in Soils, Plants, Fruits, and Animals. By Wm. P. Headden. Re-print, Proc. Colorado Sci. Soc., Vol. IX. Pp. 345-360. Denver, 1910. That arsenic is widespread in soils is not generally appreciated, and in connection with smelter fume investigations this compilation is important.

Engineer Mountain Folio.. By Whitman Cross and Allen D. Hole. U. S. Geol. Surv. Geol. Atlas U. S., No. 171. Washington, 1910. Price 25c. This is another of the excellent folios descriptive of portions of the San Juan region of Colorado, prepared by Mr. Cross and his associates. The Engineer Mountain quadrangle lies east of Rico, south of Telluride, and west of Needles mountains.

Surface Water Supply of the United States, 1907-8. Water Supply Papers, U. S. Geol. Surv. The following additional reports are now available: Pt. VII, Lower Mississippi Basin, by W. B. Freeman, W. A. Lamb, and R. H. Bolster, No. 247, pp. 124; Pt. VIII, Western Gulf of Mexico, by W. B. Freeman, W. A. Lamb, and R. H. Bolster, No. 248, pp. 171; Pt. IX, Colorado River Basin, by W. B. Freeman and R. H. Bolster, No. 249, pp. 206; Pt. X, The Great Basin, by E. C. La Rue and F. F. Henshaw, No. 250, pp. 151. All were prepared under the direction of M. O. Leighton and any may be obtained by application to the Director of the U. S. Geological Survey, Washington, D. C.

The Cherry Mine Disaster. By George S. Rice. Pamphlet. Pp. 47. This is a full and careful account of the great disaster written by a mining engineer present during the rescue work and long familiar with mining in northern Illinois. Indeed, Mr. Rice, before he became connected with the mine accident investigations of the U. S. Geological Survey, was mining engineer for the company that was succeeded by the St. Paul Coal Co. His personal familiarity with the conditions and men concerned, coupled with his wide knowledge of mine-rescue work, makes this the most authoritative account of an accident which is certain to have a large influence on American mining methods.

Theories of the Nature of the Earth's Interior. By E. H. L. Schwarz. Re-print *So. African Jour. Science*, April 1910. Pp. 234-241. Rejecting the nebular hypothesis as not only disproved but contradicted by modern knowledge, Mr. Schwarz finds on examination of the records of transmission of earthquake shocks, reason for belief in a solid interior. The results of deep drilling are shown to be contradictory and variable as regards increase of heat with depth, and the conclusion is reached that the earth consists of a self-heating crust resting upon a solid and probably cold nucleus. The sources of the apparent heat of the earth are held to be chemical reactions and radio activity. The influence of these ideas on the possibility of deeper mining is suggested.

Maryland Conservation Commission Report, 1908, 1909. Pp. 204, ill., index. Baltimore, 1909. The report of this Commission, consisting of B. N. Baker, W. B. Clark, and Edward Hirsch, while preliminary in scope, is the most elaborate yet issued by any of the numerous conservation commissions appointed as a result of the famous conference of the Governors called by Mr. Roosevelt. The Commission has attempted only a general review of the resources of the State and finds much useful investigative work already under way. Gaps are indicated and recommendations are made. The report is an excellent illustration of the useful purpose that may be subserved by a joint board correlating the work of the numerous scientific and technical bureaus that have grown up somewhat haphazardly in most American States.

A NEW CONCENTRATOR BELT

In these days of constant striving for improvement in the art of ore dressing, any detail which makes for greater recovery and larger capacity will be welcomed by millmen. The Goodyear Rubber Co., San Francisco, has just perfected a concentrator belt for which wonderful claims are made. It is like the ordinary belt except that the surface

is formed in transverse steps ¼-in. wide and $^{1}/_{32}$-in. deep, with the inclination toward the recovery point. The makers claim that it is practically impossible to overload the belt and therefore its capacity is much larger than that of any riffled or smooth surface belt, and also that cleaner concentrate and lower tailing result from a machine equipped with this belt. Detailed information will be sent by the Goodyear Rubber Co. to any one interested.

COMMERCIAL PARAGRAPHS

The Waoner Electric Mfg. Co., St. Louis, has opened an office at Birmingham, Ala. J. F. Jones will be in charge.

The Berkeley Steel Co., San Francisco, has moved its general office to the Balboa building. The works are at Richmond, California.

The Producers Rock & Gravel Co., of Victoria, B. C., has finished the installation of a plant for crushing blue trap rock to be used in macadamizing the streets of Victoria and Vancouver. J. J. Maney, of Seattle, was engineer.

C. E. Bogardus, assayer and chemist, Seattle, now has associated with him C. C. O'Louchlin, formerly chief chemist at the Mammoth smelter at Kennett, Cal., and it is the intention to take up umpire and control work as a special line at the Bogardus laboratories.

In the advertisement of the Trojan Power Co., in the July 2 issue of the *Mining and Scientific Press*, there was a halftone illustrating the effect of a blast of Trojan powder at the Cumbler quarry, Steelton, Pa. Seven thousand tons of rock were mentioned as having been displaced by a single blast of four and one-half tons of Trojan powder. This is just one-tenth of the actual accomplishment. In other words, one of the zeros were omitted from the number of tons of rock broken, seventy thousand being the correct figure—with as stated, four and one-half tons of Trojan powder.

CATALOGUES RECEIVED

D. D. Demarest Co., San Francisco, Circular No. 30. 'Pacific Rock Drills.' A pamphlet showing clearly the salient points and advantages of this well known rock drill. The design has been modified slightly in minor details, and the drill is now made in seven sizes. One feature of this drill, which commends it to all users of the piston type, is the fact that the lugs on the cylinder and the seats on the shell are not in the same plane. Therefore wear incident to use does not cause troublesome side-play making the starting of new holes so difficult. A novel scheme for taking up wear is provided. Illustrated, 32 pages, 7 by 10 inches.

EDITORIAL

CHANGES in the boundaries of the National Forests are being made constantly as surveys are perfected. On July 1, 9389 acres were added to the Sequoia forest and 65,490 acres eliminated. At the same time, by transfer, the Kern National Forest was established with headquarters at Bakersfield.

A WORLD TRADE directory is being compiled by the Bureau of Manufacturers at Washington. Several hundred thousand names of firms in foreign countries engaged in international trade have been compiled and from these a classified list of 125,000 has been selected and will be published with addresses.

PRELIMINARY figures indicate that dividends paid during July by oil companies listed on the San Francisco Stock Exchange will amount to somewhat more than $1,500,000. This is an increase of more than $100,000 over the amount paid in June and will bring the grand total so far paid to well over $34,000,000.

METALLURGY on the Rand is discussed by Mr. Horace G. Nichols in the July number of *The Mining Magazine*. Other titles include, 'Valuation of Copper in Chile,' by L. C. Stuckey; 'Mobility in Placer Mining,' by J. Power Hutchins; 'Milling of Lead Silver Ore,' by Gelasio Caetani; and 'The Oilfields of Mexico,' by H. A. Denny. As usual the editorial and special correspondence cover a wide and interesting field.

COPPER is reported to be already arriving from Africa by the shipload and the great inundating waves of red metal are said to be making a new high-level shore-line about Perth Amboy, New Jersey. Since, however, the press dispatch that contains the information credits the ownership of Tanganyika Concessions Limited to the "Guggenheim-Ryan-British Syndicate" and is otherwise full of inaccuracies, we think the American Smelting & Refining Company will be able to work up the actual present imports before the smelter becomes buried. Africa will certainly become an important factor in copper later, but just now the accent may be properly placed on the last word.

MISBRANDING has been all too common in many directions. The National Pure Food and Drug Law, while possibly a questionable extension of the power of the Federal government over interstate commerce, has undoubtedly done much good. Extension of the principle to other products such as rope, cloth, and powder, is likely soon to be urged.

There is no satisfaction to the miner in having his health protected as against impure food and drink, only to be blown up by powder stronger or weaker than he has reason to suspect from the label. Reputable manufacturers are assisted rather than harmed by such laws when properly drawn, and the others deserve no protection.

FAILURE of Mr. J. M. Guffey calls attention to the fact that he and his associates, while fortunate in their investments in oil and coal properties in Pennsylvania and West Virginia, have not done well in Western metal mining. At Thunder Mountain, at Idaho Springs, and at various other points they have dropped much good money without adequate return. To succeed in metal mining requires more than ability to make prompt decisions and the readiness to accept long chances that characterize the successful oil operator. Mr. Guffey has acquired considerable experience at a rather large expense. He still owns many valuable properties and we wish him better success in the future.

FORMAL opening of the new Portland mill at Cripple Creek was celebrated July 19 in the good old American fashion by speeches and a luncheon attended by a number of the Colorado mining engineers and metallurgists. The new plant is designed to treat, without roasting, ore assaying $2.40 per ton, and 8000 tons are said to have been handled at a profit of 75 cents per ton in the three weeks preceding formal opening. The process is one of concentration and simple cyanidation, except that while agitating the slime, a secret solvent is added. It is a matter of regret that despite the friendly relations obtaining between Colorado metallurgists, the officers of the Portland company, because of threatened patent litigation, have not felt free to announce the details of the method. The building of this mill is another step toward the winning of the greatest metallurgical prize in Colorado, successful treatment of low grade ore from Cripple Creek.

TENNESSEE zinc mines are again attracting attention. As is well known, eastern Tennessee and southwestern Virginia contain considerable areas of dolomite in which blende and calamine are widely disseminated. At various times considerable quantities of ore have been shipped. Of recent years the zinc industry in this region has not flourished and the Bertha furnace at Pulaski, Virginia, has shipped in ore from New Jersey and elsewhere in order to continue to produce the high-grade spelter for which it is famous. Conditions in the zinc industry, fortunately, are improving, and Tennessee with other States is like to benefit. The Grasselli Chemical Company has become interested, followed by the Osgood Exploring Company of Chicago. The Grasselli company in particular is well equipped to solve the metallurgical problems of the district. At Park City, Utah, by an ingenious combination of close sizing and dry concentration, the metallurgists of this company are making a marketable product from an ore exceedingly difficult to handle. In Wisconsin and elsewhere the concern is a large buyer of low-grade ore and at the works at Cleveland, Ohio, and Parkersburg, West Virginia, its technical men have been doing excellent work.

MINING ENGINEERS rarely devote much attention to politics. The country would be better served if they did. Farmers and lawyers form an undue proportion of the membership of legislative bodies, and a few engineers would prevent a good many impractical experiments at the same time that they would naturally be constructive in their tendencies. California is the only State represented in Congress by a man who gives his occupation as 'mining engineer.' Mr. W. F. Englebright, who represents the first California district, has abundantly proved his right to the title by excellent work at Nevada City and elsewhere. At Washington he has been very influential in shaping legislation relative to mining matters. It was due to his insistence that lands containing precious metals were excepted from the operation of the new withdrawal law, and in the creation of the Bureau of Mines and other matters of concern to the mining industry he has been active and effective. We do not always agree with him, but, if it be not permitted a technical paper to express an opinion in such matters, we may at least make clear our hope that the voters of his district, in which there are large mining interests, will continue for many years to send him to Washington. We like to think that there is at least one mining engineer in Congress.

COLORADO mining conditions have not been altogether satisfactory in the last year or two. There is undoubtedly a shortage of certain sorts of ore formerly mined in abundance, and the inflow of capital has been checked, to some extent at least. Real conditions are not as bad as they appear at first glance. Improvements in hydrometallurgy have diverted to mills, ore that formerly went to the smelters; and erection of furnaces in Utah and elsewhere has decreased the amount of ore from other States reduced in Colorado. If it be true that the amount of outside money now seeking investment in Colorado mines is less than in former years, it should be remembered that irrigation and other enterprises make new drafts on the supply. It is fair also to recall the fact that much of the money formerly sent to Colorado was in no sense invested. It was spent in stock exchange gambling. The benefit from such expenditure is dubious, to say the least. Colorado is growing up and is resolutely putting these excesses of youth behind. On another page we publish an address prepared by a committee appointed at a recent meeting of the mining men of the State. It is well worth reading, and we shall watch with interest the career of the new chapter of the American Mining Congress that has been organized. The representative character of the men concerned in the movement may be inferred from the list of directors chosen. They are, Messrs. E. A. Colburn, W. J. Cox, E. M. Delavergne, A. W. Warwick, Bulkeley Wells, A. L. Burris, R. L. Martin, John R. Wood, D. W.

Brunton, John Dalzelle, A. G. Brownlee, J. F. Callbreath, Max Boehmer, Philip Argall, J. W. Dean, and A. V. Bohn.

TEXAS iron ores are now attracting attention. It is known that the big steel companies have had men examining the field; and shipments to the East have been made. Iron ore occurs widely distributed in the central and northeastern parts of the State. Mr. E. C. Eckel, who examined the deposits in 1904, placed the total area of the iron ore districts at 1000 square miles. The ore compares favorably as to quality with the brown ores of the Appalachian region. The individual beds, however, are thin and a wide area would need to be drawn on in supplying any one furnace. Fortunately the region is agricultural so that railways need not rely on ore alone for freight. The nearness of the field to high-grade coal in Arkansas and Oklahoma, makes it probable that smelting can be done to advantage and establishment of a new centre of pig iron production is entirely probable.

Mining Matters at Washington

Bureau of Mines matters continue to attract attention. The plans for this year announced by the acting director, Mr. George Otis Smith, are excellent, though a larger allotment of funds to investigation of problems relating to metal mining will naturally be expected next year. For a preliminary survey of the field, however, the provision is adequate. The new work is being systematically built on the old, and full advantage is being taken of the excellent progress made by the Technologic Branch of the Geological Survey under Mr. J. A. Holmes before the establishment of the Bureau. Indeed, while Mr. Smith is quite unwilling to endorse Mr. Holmes for the position of Director, he apparently has no such hesitation in adopting his plans. Criticism of the position taken by Mr. Smith and his associates in the matter is widespread. At the meeting of Colorado mining men, reported on another page, strong resolutions in regard to the matter were passed. At the Grass Valley meeting of the Mining and Metallurgical Society of America, the feeling voiced was the same. That the men concerned are not merely 'a few talkers and promoters' who 'take themselves too seriously' may be seen by looking over the list. It is interesting to note that whereas Mr. Smith has condemned Mr. Holmes for being too active a 'lobbyist,' he has found it necessary to enter upon a press campaign of explanation of his own activity in behalf of a rival candidate. The truth is that the only centre of opposition to the appointment of Mr. Holmes, the logical man for the place, is the Geological Survey, and that there has been in the latter organization a good deal of jealousy, and not a little of what others regard as prejudice against Mr. Holmes and his work. So far, no good reason against his appointment has been made public, and until better reasons than any yet advanced be given we shall continue to urge the appointment as Director of the Bureau of Mines of the man most intimately associated with its creation, Mr. Holmes.

We are not among those who fear harm to the Geological Survey because of the establishment of the Bureau of Mines except as harping on the matter may produce that result. As a matter of fact the Survey has been weakened rather than the reverse every time it has taken up work aside from its main and legitimate duties. It has frequently had to assume related functions for which no other provision has been made. As a temporary matter we believe this proper; but if the new work does not shortly win the support that it needs, if it can not stand on its own merits, it is a source of trouble and danger to the Survey and had much better be dropped until conditions change for the better. Ethnology, Forestry, Reclamation, and now Technology, have been successively developed and then cut off from the Survey, but despite these 'losses' the Survey is now stronger, and better established in the good will of the public and of Congress than at any time in the past. It will continue to occupy this fortunate position so long as it does its own work excellently and confines its activities in other directions to sympathetic assistance. Any other attitude on the part of the Survey or its friends creates suspicion. It is a case of protesting too much.

Stock-Selling Geology

Cobalt has had to struggle against many difficulties, not the least of which has been the 'favorable' reports circulated by many stock-selling companies. In one such report a 'professor' who states frankly, "My views may differ widely with the views of other geologists" (which they do), lays much stress on 'Lines of Weakness.' In defining them he says:

"To explain what a Line of Weakness means, I may compare the same with a regional metamorphism —denoting that the rocks for a long distance in certain directions have been altered by some agencies— however, in our case here the lines of Weakness do not metamorphose the rocks regionally, but locally, in other words, the Line of Weakness represents a big contact zone fissured all through and probably including big fissures or even an abyss running through a considerable length of the region, dividing either two or more different rock formations and denoting the different physical aspects of the rocks of the same origin, but separated through different causes—like through differential movements of the earth, or the shrinkage of the crust, etc."

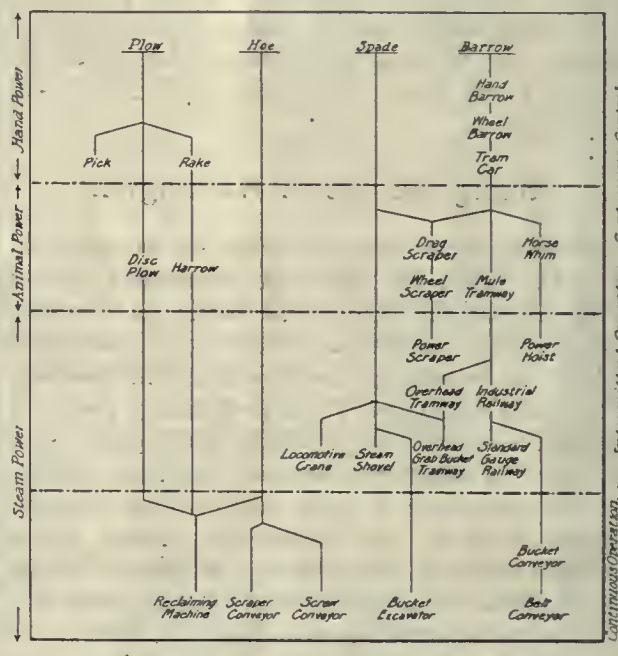
We quite agree that there is a line of weakness here but perhaps we would not define it quite as does the professor whom, we are told, is "a mining geologist of world-wide experience." This lends peculiar interest to his announcement that "I have found at last the very essential cores of the Diabase, which originated the silver deposition in this district, then the Diabase must be underlaid with Huronian or Keewatin rocks at a minimum depth of 500 to 600 feet below Giroux Lake level." There has been much such stuff written about Cobalt and apparently more will be sent out describing Porcupine. The fact that the new Canadian districts make steady progress nevertheless is an excellent assurance of their real value.

Material-Handling Machinery and Its Evolution

By E. H. Messiter

At a very early period man, or his predecessor, must have found it necessary to dig and move earth. This must have occurred long before there was anything with which to do it except the hands. At a certain stage one can imagine some crude implement brought into use to help in the operations of scratching, scraping, digging, and holding and carrying the earthy material. This implement was the progenitor of the whole family of devices we use today for handling material. Remembering that these devices are merely extensions of the human hand and have been made by it only to perform the wishes of the owner of the hand, it is natural to assume that they have been evolved according to the same laws that have controlled the development of the hand itself. Viewed in this way, these implements belong to the animal kingdom and their characteristics are a part of the characteristics of the men that made them. So we can classify them into genuses and species, and study their variations and survivals in much the same way as if they were animals. We ought to be able to construct the family trees of our material-handling devices, and may possibly find the resulting classification instructive.

Starting with the first implement, which may have been a thin flat piece of stone performing the four functions of breaking, scraping, digging, and holding or carrying earth, we may assume that it was early differentiated into the ancestors of the plow, the hoe, the spade, and the barrow. The two fundamental operations are breaking and moving. The plow devotes itself almost entirely to the former, while as we pass successively to the hoe, the spade, and the barrow, the element of moving becomes more and more prominent. The plow, like its near relatives, the pick, rake, and harrow, has undergone changes in material and form, adapting it more perfectly to its work, but these changes have not given new names to the later forms. The disc plow is the most radical development. Only recently has the plow entered into the design of material-handling machinery, and, with the exception of a cyanide tank excavating device, only in combination with one or more of the other elementary implements. The hoe has had a history similar to that of the plow, but unlike the plow it may be regarded as the direct forerunner of some of our common material-handling machines, for instance, the scraper and screw conveyors, both of which are equivalent to continuously acting hoes. The spade or shovel has simply grown by combination with various elementary machines and prime movers into the steam or electric shovel and the grab-bucket and scraper-excavator. The continuous-bucket excavator is essentially a series of shovels and, therefore, a direct descendant in this line. The barrow family is perhaps the most interesting of all. The first barrow was probably a slab of stone or other material on which more earth could be carried than in the hands. The barrow proper, at an early period came to have four handles, so that it could be carried between two men. It was then a hand-barrow. Later a wheel took the place of two of the handles and the wheelbarrow had come into existence. With increase in capacity and efficiency the wheelbarrow came to have two wheels. While the wheelbarrow was always guided by hand, something in the nature of a track was doubtless used at an early period. At a certain stage of the development the number of wheels was increased to four and the tracks took a form that permitted them to guide the wheels. Then the barrow became a car. Animal power and then steam power were called in and the cars were coupled into trains, initiating the industrial railway. The barrow body began to develop special features to assist in loading and unloading, and with further increase in size and another increase in the



Evolution of Machinery for Handling Materials.

number of wheels, the standard-gauge gondola and hopper cars came into existence. After the arrival at the four-wheeled stage an independent branch of the barrow family was started. Instead of making direct application of animal or steam power, cars began to be hitched to chains and ropes. When these were endless the cable railway, or its equivalent, made its appearance. At this point is noted also the inclined and vertical hoists in which the rope is attached either to the car or bucket, or to a carriage or cage on which they rest. The cars at first were not permanently attached to the rope or chain, but later this was done and the cars placed close to each other, end to end, or even over-lapping. This was probably the first conveyor. Like many other members of this branch of the barrow family, the bucket-conveyor is not limited to transportation in directions nearly horizontal. Some of them, with slight modification, carry material vertically. In some forms of the continuous-bucket conveyor the 'cars' returned to the original flat shape of the barrow, and the conveyor became a continuous apron. Then an adaptation to environment as bold as some that are found among animals and plants took place. The axles of the wheels were made stationary and the

apron rode on the wheels. A belt performed the duties of the chain as well as of the apron, and the belt-conveyor was born.

Now, look at some of the appliances of mixed ancestry. The drag-scraper and wheeled-scraper are combinations of shovel and barrow. The grab-bucket and trolley, running on a wire rope, or a bridge, are combinations of a higher order. In each of these devices the barrow has one or more cutting edges which make it also a shovel. A combination of the plow, the harrow and the hoe has recently been made for gathering and mixing ores and fluxes from mechanically-made ore-beds. This has been called a reclaiming machine. The accompanying diagram shows these supposed family relations of the material-handling devices at a glance. In the margin are shown the transitions from man power to animal power and to steam (or electrical) power. More significant is the line marking the transition from intermittent to continuous operation. All of the devices above this line require that the hand that controls them shall not relax its grasp while they are in use. The hand may hold the implement itself or hold a bridle or a lever, but if the hand leaves the mechanism entirely it ceases its work. In the case of the continuously-operating devices, on the contrary, the hand that controls them may leave them for an indefinite period. If we exclude the method using water, air, or explosives in the handling of material, it would appear that we can find a place on this diagram for any of the machines in common use for handling earth or other loose or broken material.

The period of the lifetime of the *Mining and Scientific Press* has witnessed many of the applications of mechanical power to the older appliances and the greater part of the development of the continuous devices. During the latter part of this period the newer devices have been extensively introduced into mining and metallurgical plants. In general, the greater the tonnage being handled the greater the need of mechanical handling. We would thus expect to find the best examples at the larger mines and at concentrating and smelting works where the tonnage from the smaller mines is combined. The installation of steam shovels and hoisting and conveying machinery at the more important mines is well known. Here may be noted the marked tendency observable in recent years toward the introduction of crushing machinery nearer and nearer to the point where the transportation of the ore commences. Crushing makes the mechanical handling easier and mechanical handling makes crushing easier. The concentrating processes begin with crushing, and there is an increasing tendency among smelting authorities to eliminate large lumps from the charge, and thus to commence their operations in the same way. In smelting works the handling of material of the kind here considered is nearly coextensive with the operation of furnace charging. The methods of handling preparatory to the actual introduction of the charge into the furnace are largely determined by the necessity of weighing and mixing the several ingredients. It has been customary to store the different materials separately and then weigh out the proper quantities in barrows or cars. When the number of ingredients is too great to be handled conveniently in this way it has been the practice to bed a part of them by spreading them in successive overlying layers on the ground. This has been done by hand. The cost and inherent imperfections of this method have prevented its use for mixing the entire charge. Within the last decade machinery has been applied to this operation and at two large copper smelting plants all of the charge is bedded and reclaimed by cars and steam-shovels, or by belt conveyors and special reclaiming machinery. At several other plants machinery is used in bedding part of the charge but not in reclaiming it.

The tendency to substitute the newer, continuous methods of handling is becoming increasingly evident, and so the use of cars and barrows for the moving of material in course of treatment is decreasing. A new factor which will doubtless accellerate this tendency is the recent development of efficient and reliable apparatus for weighing material while in motion on conveyors.

Flint pebbles are not exported to the United States from any of the three principal seaports of Germany, namely, Hamburg, Bremen, and Stettin. They are not found in the neighborhood of the above places. Such pebbles, however, are gathered, although in quantities barely sufficient to supply local demands, in the quarries of some of the portland cement concerns in Germany, particularly the Hemmoor works near Cuxhaven. These flints are not round and, before they can be used for grinding purposes, have to be treated until they become of the right shape. For this purpose they are used in pans where the clay and lime are washed, and when sufficiently round are transferred to the tube-mills. Flint pebbles are also found in the chalk works on the islands of Rugen and Wollin in the Baltic, and thence are exported in small quantities to Russia. They are also found on the Danish coast. The Hemmoor works are producing the flint pebbles, but not in sufficient quantities to fill local demands, and no portland cement factory in Germany sells the pebbles. The Hemmoor company has bought good pebbles from several firms in Copenhagen, Hamburg, and Stettin. One of the largest German handlers of flint pebbles states that flint pebbles, such as are used in tube-mills, are not found in Germany to any considerable extent. Few, if any, flint pebbles are exported from Germany to the United States. The principal sources of supply are the French coast from Havre to Calais, the southern coast of England, and some portions of the Danish coast. The exact amount of the foreign trade of Germany in flint pebbles cannot be stated, as these products are classed in the official statistics under kieselgur, quartz, quartz sand, and are not separated.

Power required to start tube-mills in motion is relatively great, being approximately 35 hp. for a 13 ft. by 3 ft. 3 in. mill and 70 hp. for a 22 ft. by 5 ft. mill, but when under way the power required is diminished to about 25 hp. for the smaller and 50 hp. for the larger mill.

Colorado Mining Conditions

The following is the report of the committee appointed for the purpose of organizing the mining industry of Colorado at a meeting called by the American Mining Congress, July 13, 1910.

To the mining men of Colorado in meeting assembled: The members of your committee appointed at a general meeting at Denver called by the American Mining Congress, July 13, acknowledges the honor bestowed upon them and report, that after giving careful consideration to all the remarks of the speakers of the meetings and giving due consideration to the volume of correspondence which has been received from all parts of the State, there appears to be an almost universal demand for the formation of a Colorado Chapter of the American Mining Congress. Your committee therefore presents and incorporates as a part of this report a preamble setting forth the objects of the association and a set of by-laws under which it can commence to do business. In presenting these by-laws we wish to say that they have been made as simple as possible in order that after the organization is completed, the mining men of the State may have the opportunity of giving fuller voice as to laws under which the Colorado Chapter of the American Mining Congress should continue to exist and do its work. Your committee believes that in addition to the preamble to the constitution of the proposed Chapter that it is advisable to indicate what, in its judgment, is the main and immediate work to be done by an association of Colorado mining men. Before doing so, however, it is premised that the suggestions herein made do not comprise all the work that must be done, but simply the work which should be immediately taken in hand. Our suggestions are as follows: (1) The Colorado mining men should sustain the officers of the American Mining Congress in their efforts to see that an adequate Bureau of Mines be completely organized and continuously sustained and to see that the mining interests of Colorado receive the proper Federal encouragement and protection that is its due. (2) It is the obvious duty of the Colorado mining men to see that all the State organizations that bear upon mining should fulfil their functions in the best interests of the industry and to sustain as far as possible the efforts of the officers to improve the services that they are rendering the State. We particularly mention the office of the Commissioner of Mines, the School of Mines, the State Geologist, and the Commissioner of Immigration. (3) That certain bills be carefully considered for representation to the State legislature and that other needed bills be prepared and organized efforts be made to secure their passage. (4) In view of the apparently settled national policy of forest reservation and mineral conservation, it is of importance that the Colorado mining men should seriously consider the new conditions under which they are working and to secure, if possible, such governmental regulations as will best serve the interests of the State at large and of the mining industry in particular. (5) That the collection of such commercial statistics as do not come before the purview of the State and Federal officers be one of the principal objects of the association. It is needless to say that in this connection it is necessary to have the widest publicity and therefore the more active co-operation of the State press should be most cordially invited. (6) The relationship of the mining industry to the public service corporations should be a matter of deep concern. It should be the object of the association to endeavor to harmonize the relation between all branches of the industry to the end that all interests be properly served and protected.

In regard to the question of the protection of investors in mining enterprises, it is the belief of your committee that this matter be attacked very conservatively and yet efficiently, but in such a manner that no aspersions be cast upon worthy enterprises. This is a matter that should be approached cautiously yet with perfect candor. The problem is an exceedingly difficult one, and we feel that in attacking the operations of the dishonest promoter every care should be taken so that the interests of those who are honestly and in good faith endeavoring to raise capital for mining enterprises be not jeopardized. In presenting this report, your committee in no way wishes to bind the actions of the proposed organization, but simply to indicate to the miners of Colorado what in their judgment, after careful consideration, appears to be the more pressing needs of the mining industry within the borders of the State. Finally we wish to say that it is the opinion of your committee that the mining industry in Colorado is by no means in a moribund condition. In the San Juan, Leadville, Cripple Creek, and in the northern mineral fields there is a great deal of activity and the mineral production of the State on the whole is at this time fairly satisfactory. However, we recognize that the industry is not making the progress that the resources of the State warrant.

At the meeting the following resolution was unanimously adopted: Whereas, the interests which united in seeking the creation of a Bureau of Mines have almost, if not quite unanimously urged the selection of J. A. Holmes as the Director of this new Bureau, and whereas, the success of the Bureau is being jeopardized by a temporary appointment and the appointment of Mr. Holmes is being prevented by forces which have always opposed the creation of a Bureau upon the ground that it could serve no useful purpose, and whereas, the success of the Bureau for which Western mining interests have been fighting for fourteen years requires that the Bureau shall be put in charge of a man who understands the need of the mining industry and who believes that the Bureau can perform important public service. Now therefore be it resolved that the mining men of Colorado, in convention assembled, do most respectfully and urgently petition the President of the United States that he shall forthwith appoint as Director of the Bureau of Mines, Joseph A. Holmes; and be it further resolved that a copy of these resolutions be forwarded to the President, William H. Taft, and Hon. R. A. Ballinger, Secretary of the Interior.

Gold Mines in Eastern Oregon

STAFF CORRESPONDENCE

The mine of the Columbia Gold Mining Co. has been in successful operation during the last 14 years. Its location is on the great lode that strikes northeast-southwest through the slate formation of the Cracker Creek mining district, in Baker county, Oregon. The mining properties on this lode that are important in the history of the county comprise the Blaisley-Elkhorn, North Pole, Eureka & Excelsior, Columbia, Golconda, Amazon, and Bunker Hill, the distance from the Baisley-Elkhorn, on the north, to the Bunker Hill on the south end of the lode being seven miles. The Baisley-Elkhorn was in operation several years, but is now idle; the North Pole, belonging to Baring Bros. of London, was operated 10 to 12 years under the management of Emil Melzer, and during the greater part of that period it made a record of yielding the highest profits of any mine in Oregon. It was closed within the last two years because of the failure of the owners to allow sufficient funds to be set aside to continue the development necessary in keeping up ore reserves. The general verdict of mining men is that the North Pole is still a good mine. The property is well equipped with an aerial tramway and a mill for concentration and cyanidation. The E. & E. group lies between the North Pole and Columbia and is fairly well developed from a vertical shaft and adit levels; it is also equipped with a concentrating mill that was erected 14 or 15 years ago. It has ore of the same type as that of the North Pole. The property was located in 1886 and during the intervening years it has been owned by Jonathan Bourne, though Ladd & Tilton, bankers of Portland, are now reported to be most heavily interested. Ten to twelve years ago the mine and mill were operated by Mr. Longmaid, as lessee, who had fair success. Operations since then have been attended by various difficulties and the property is now closed, though it is considered that it has good orebodies and that successful operating is within the possibilities.

Mine and Mill of Columbia Gold Mining Co., near Sumpter, Oregon.

The Columbia G. M. Co. is a close corporation, all the shares in which are held by Edward W. Backus and Wm. F. Brooks of Minneapolis, and Frank S. Baillie of Sumpter, Oregon. Mr. Baillie is manager, and all the development, construction work, and production accomplished within the last 14 years, have been under his personal direction. During 1909, there were mined and milled 17,165 tons of ore of an average value of $11.13 per ton, the cost of operating having been $5.25 per ton, distributed as follows: Asaying, 10c.; general expense, 5c.; office expense, 10c.; insurance and taxes, 10c.; mining and development, $3; crushing, amalgamating, and concentrating, 80c.; cyanide treatment in tailing plant, $1.10. Aside from the mill production there was a shipment of one carload of ore direct to the smelting plant which returned $364 per ton. In the milling processes 35% of the total extraction is made on the amalgamating plates, 50% by concentration, the balance by cyanidation in the tailing plant. The ore consists of quartz carrying gold, silver, and iron sulphide; it contains, probably, 90% silica. Copper, antimony, and arsenic occur in unimportant percentages. The Columbia is, in the main, a gold mine, the ore containing one ounce gold to three ounces silver. The tailing from the concentrators passes to the cyanide plant by a launder. The sand and slime are separated by means of hydraulic classifiers; the sand is leached in percolating vats, the slime being cyanided in agitation tanks of the company's design. The concentrate, which averages $80 per ton, is hauled 7 miles to the railroad at Sumpter and shipped to the Tacoma smelter.

The mine is opened to a depth of 918 ft. by a 3-compartment, vertical shaft, that was sunk in the hanging wall. The vein, which has a dip of 80°, between argillite walls, varies in width from 5 to 75 ft. The foot-wall is well defined, and most of the ore is found next to it; the hanging wall is not so distinct. While the vein is continuous and defined, the ore occurs in lenticular bodies, extending horizontally along the strike and in contact with the foot-wall. These lenses of ore average, approximately, 4 ft. in width. The shaft stations are 100 ft. apart, a cross-cut from each station opening the vein and establishing a working level. Extensive driving has been done on the vein from all stations, and in opposite directions from the shaft. In this manner the vein has been opened for 3000 ft. on the company's ground. At present ore is being taken from the 100, 400, and 500-ft. levels, as well as some from No. 2 and 3 adits, by which the ground higher than the collar of the shaft is developed. It is estimated that 300,000 tons of ten-dollar ore are exposed by present development. Electric power, purchased from the Eastern Oregon Light & Power Co., serves to operate the hoist, pumps, and mill machinery. The air-

compressor is operated by water-power. The surplus water in the mine is handled by Aldrich electric pumps, placed at the 700-ft. station, lifting 500 gal. per minute; and by auxiliary pumps at the 500-ft. station. Hand-drilling is in vogue here, principally because the exhaust oil from machine drills made some of the ore greasy and this condition interfered with amalgamation on the plates. Whistle signals, instead of bell or flash-light signals, are in use. The whistle is attached to the air-receiver at the collar of the shaft, and the receiver is connected with the air-compressor. It is blown by pulling a cord at any station in the mine. This and other mines of Cracker Creek district are in the National Forest, and therefore the cutting of timber for mine uses is subject to the regulations and prices established by the Forest Service.

The Northwest Smelting & Refining Co., which owns the Sumpter smelting plant, is expected to start operating some time this season, according to the plans of F. W. Scofield, the manager, who states that he is now receiving ore for custom work. The plant has a 44 by 140-in. copper furnace, and is said to be in good physical condition. Mr. Scofield figures on obtaining silicious ore from the Sumpter district and iron and copper sulphide ore from the Iron Dyke mine on the Snake river. This smelter operated part of 1905 and 1906, during which period it is stated to have produced and shipped 41,000 oz. gold and 150,000 oz. silver, from ores mined in this section.

FREIGHT RATES FROM THE COEUR D'ALENE DISTRICT

In connection with the complaint of the Pennsylvania Smelting Co. before the Interstate Commerce Commission, some interesting facts were brought out relative to the movement of lead concentrate. It appears from the summary by J. C. Clements, the Commissioner who heard this case, that the rate charged for the transportation of ore and concentrate from the Coeur d'Alene district to both Carnegie, Pa., and Atlantic Coast points is $12 per net ton, though the haul to Carnegie is about 440 miles less than the haul to the Atlantic Coast points. From all other points in the United States where such products originate, the rates are, as a general rule, 60c. per ton less to Carnegie than to New York. The complainant corporation alleged that the rate of $12 was in violation of the act to regulate commerce, and asked that a differential of 60c. per 2000 lb. be allowed Carnegie so that the rate would be $11.40 per ton. The defendant railway companies relied only on one defense, namely, that the $12 rate to the Atlantic Coast points was made necessary through water competition, and was extended westward as a blanket rate as far as Chicago, and that under the circumstances a higher rate to Carnegie might with perfect propriety be established. In support of the contention that the $12 rate to the Atlantic Coast points was compelled by water competition, evidence in the form of two shipments of pig lead from San Francisco to New York by water was presented, which shows that there was charged, respectively, $4 and $5 per ton. The rate from the Coeur d'Alene district to San Francisco by rail and water is $5.50 per ton, which would make the entire rate upon these shipments from the Coeur d'Alene district to New York by water and rail $9.50 and $10.50 per ton, respectively. But this defense was destroyed, as the defendants in a Great Northern tariff published a rate on pig lead from Seattle, Everett, and Tacoma to Carnegie of $12.10 per ton, and to New York $12.70 per ton, there being a differential of 60c. in favor of Carnegie. Moreover, from the testimony it appeared that the complainant is the only smelter and refiner of lead ore and concentrate between Chicago and the Atlantic coast, and therefore the only one affected by the rate in question. One of its competitors has a smelter at Perth Amboy, N. J., and obtains the same rate upon ore as complainant. It is asserted that the Perth Amboy smelter is owned by the same corporation which owns smelters at East Helena, Montana, and various other places. It further appears that these smelters situated at Perth Amboy and East Helena can lay down pig lead at any point in the United States at a much less freight rate than complainant. For instance, the smelter at East Helena can haul 55% lead ore from the Coeur d'Alene district to East Helena, there smelt it, and deliver the bullion to Pittsburg at a freight rate amounting to $9.40 per ton less than the complainant can haul the same ore from the same originating territory and deliver it in Pittsburg which is eight miles from Carnegie and practically the home city of complainant. When 75% ore is hauled the East Helena smelter can lay down the product in Pittsburg at a rate amounting to $4.65 per ton less than the complainant. Apparently the complainant can compete more favorably when it buys high-grade ore than low-grade ore; this being due to the fact that, while the rate on the ore is a little lower than that applied on the product, the greater tonnage of the ore makes the rate applied thereon commensurately higher. Why it should be handicapped in drawing its supply of ore from the Coeur d'Alene district is not of record. The railways were therefore required to establish and maintain a rate from the points in the Coeur d'Alene district to Carnegie, Pa., not in excess of $11.40 per ton, or of 95% of the rate contemporaneously charged to Perth Amboy, N. J., and other points now taking the $12 rate.

USEFUL WATER TABLE

The following compilation will be of use to those who wish to know the relation that head and volume of water bears to the size of nozzle that may be employed to best advantage:

Head	Miner's inches.				
feet.	2-in. nozzle.	2½ in.	3 in.	4 in.	5 in.
100	80	125	185	322	500
150	100	155	225	400	625
200	115	180	260	460	715
250	130	200	290	515	800
300	140	220	320	565	880
350	140	240	345	610	950
400	150	255	365	650	1,000

The miner's inch as established by legislative act in several of the Western States is 1½ cubic feet per minute.

Hydraulicking in Trinity County, California

Trinity, Siskiyou, Humboldt, and Del Norte counties in northern California, are not affected by the laws inhibiting hydraulic mining, as the drainage of those counties is not tributary to the Sacramento river, but is to the westward, directly to the Pacific. As a consequence large hydraulicking operations are still carried on. The largest mine is the La Grange, five miles west of Weaverville, at the head of Oregon gulch. The geological conditions are described by D. F. MacDonald, in the advanced sheets of 'Contributions to Economic Geology for 1909.'*

The deposit at the La Grange mine is part of an old channel formed by Stewarts Fork or by Trinity river. From rim to rim the width of this channel is almost a mile and its greatest depth is 600 feet. Its direction here is determined by its northern rim, which is a great, smooth, slickensided fault-plane trending N. 70° E. and dipping 22° S., and the striae on which make a small angle with the horizontal. Along this fault a parting of sticky clay, a few feet thick, separates the gray schistose rock on the north from the dark, slaty, rough-surfaced bedrock on the south side. The stratification of the gravel along this plane is much disturbed. The wash contains a great variety of rock; about 12% of it consists of boulders weighing from 100 pounds to many tons. Near the lower part of this bed is a lens-shaped layer of cement gravel, having a maximum thickness of 50 feet. Below this indurated bed uncemented stratified wash rests unconformably on an older blue gravel.

A maximum flow of 3400 miner's inches of water is conveyed to this mine from Stewarts Fork, 29 miles distant. From a reservoir eight and a half miles of flume brings the water to the first inverted siphon, which has a span of 4800 feet with an 1100-ft. depression and is of 30-in. steel pipe with lower lengths one-half inch thick. Beyond this siphon there is a 9000-ft. tunnel, two inverted siphons, one with 150 ft. difference between head and discharge, the other with 60, and a flume and ditch leading to the reservoir at the penstock. The flume, 2 ft. wide in the bottom, 6 on top, and 4 deep, is built of 4 by 6-in. framework lined with 1½-in. boards, and cost $5000 to $7000 a mile, the tunnel $10 a running foot.

From the penstocks three main pipe lines carry the water to six giants working under 450 to 650 ft. of head, and three of these, together with a smaller one, work at once. The largest pipe is 30 in., the smallest 15; the gauge is No. 4 to No. 7. The mains have 15 to 18-in. inlets and 5 to 9-in. nozzles and are fitted with safety clutches, invented by Pierre Bouery, the manager, to prevent accident in case the kingbolt should snap and the top of the giant break loose. These giants are fitted with a modified form of 'bootleg' deflector and with saddles, so that the piper rides the swinging pipe and has it under control at all times with minimum exertion and maximum safety and efficiency. The reservoir gates are fitted with automatic floaters for regulating the discharge so that the same amount of water a minute will flow whether the reservoir is full and the pressure great or the reservoir nearly empty and the pressure correspondingly low.

In mining, the 600-ft. bank is usually undercut along the bottom and slowly crushes down, breaking even the cement gravel near the base. This undercutting saves the large blasts formerly necessary, and now only the larger boulders and masses of cement gravel which do not crush small enough are blasted. Large masses of clay are encountered along the main fault-plane; these are bored with an Ingersoll wood-boring machine, using a ⅞-in. bit, and blasted. The high-pressure pipes accomplish the cleaning of the bedrock, so that scraping is unnecessary. The sluice-boxes are 4 by 6 ft. in cross-section and are set into bedrock cuts. They have a uniform grade of 8 in. per 12 ft. for all except the first 70 boxes, which are set at 7 in. The sluice is lined with 40-lb. steel rails throughout its 3000 ft. of length. The bottom rails are all set crosswise, except a few lengths near the upper end laid lengthwise to help give the material a start. Rails set lengthwise and 8 in. apart last two months; lengthwise and 5 in. apart, four months; crosswise and 5 in. apart, six months. The interval of 5 in. has been adopted for the bottom rails; these are held in place and spaced by cast-iron lugs bolted to one rail and having a square depression in the other end, which fits on the head of the bolt holding the lug to the next rail. The rails may thus be readily removed at clean-up time without unscrewing bolts. They are set on 2 by 6-in. pieces spaced with 4 by 6-in. wooden end and centre blocks, thus forming 10-in. riffles. When the top part is worn off the rails are heated in a special furnace, straightened, and used to line the sides of the boxes. For this lining they are set with the web or stem of the T between thick plank strips and with the flat basal part projecting out over the strips, thus armoring the sides of the sluice. Long bolts passing downward through the strips and rail stems hold them in place. The rails are shipped from San Francisco already drilled and cut in 6-ft. lengths. Each length, with lugs attached, costs at the mine, after paying $1.25 for freight from Redding, about $5. Each of the 140 or more sluice-boxes contains 30 transverse rails. About 1400 ft. from the head of the sluice the material can be diverted by means of a steel door to another part of the dumping ground. This exit gives more dump area and facilitates the clean-up of the lower sluice. Through this iron-clad sluiceway material is washed at the rate of 1000 cu. yd. per hour, boulders up to seven tons in weight being carried through. Formerly the sluice was lined with wooden blocks 16 by 16 by 13 in. These wore so rapidly that a clean-up and relining were necessary every two or three weeks. Sand, too, often gave trouble, and it was difficult to save the fine gold if the sluice was allowed to carry anywhere near its full capacity. With the present equipment the sluice can be run full day and night, and only three clean-ups a year of the first 40 or 50 boxes are necessary.

*Bull. 430-A, U. S. Geol. Survey.

The Black Hills of South Dakota—II

By William H. Storms

As was natural, the placers first attracted attention, and it was this that resulted in the great rush to the Black Hills. The various early expeditions having reported the presence of gold in that region, and these statements having been confirmed by the Jenney-Newton expedition of 1875, thousands of men, women, and children left their homes and hastened to the new El Dorado, and a great many claims were located in the Hills, even before the expedition had completed its labors and left the country. Later these people were taken from the Hills by the soldiers, under orders from Washington. The Indians were about the only serious menace to these pioneers, and many an unfortunate gold-seeker went to his last reward at the hands of the hostile Sioux. Singly and in small parties, more than a hundred men, women, and children perished in the most horrible manner after being captured by the Indians, in or near the Hills. Men at work in the placer pits were always armed, and lived, day and night, in constant fear of an attack from the Sioux. One party with several wagons—men with their families, seeking a new home in the land of gold—were surprised at night in Red Canyon, one of the southern gateways to the Hills, and the entire party was massacred. This sad ending to what must have been the enthusiastic hopes of the members of the party, should have acted as a check on others coming into the Hills, but only taught them greater caution—to send scouts ahead and to the rear, and to have at night guards always on watch. Some fellow, with a bit of sentiment in his make-up, nailed a board to a pine tree by the roadside at the entrance to Red Canyon, on which was painted the following expressive warning:

"Travelers, look to your rifles well,
This is the mouth of Hell—the Red Canyon."

The early comers mined industriously on the several streams of the Central Hills, on French, Spring, Castle, and Rapid creeks, mostly. Gold could be found almost anywhere, it seemed, but unfortunately for the exaggerated hopes of the majority, the places that were rich enough to pay well were not numerous. Nearly all the miners were inexperienced —farmers, small merchants, clerks, and artisans of the Middle West, who had come in search of the sudden fortune that transportation literature and newspaper stories, had led them to believe could be had merely for the seeking, with the minimum of work and in the shortest possible time. Among the multitude, however, were many men from the mines of Colorado and Montana, as well as from other mining States, and these quickly introduced the methods and appliances they had learned by experience elsewhere were essential to success, but even these 'old timers' were often disappointed, for they failed to find gold where it should be, while the 'tenderfoot' struck it rich in the most unlooked-for and impossible places. The number of gold seekers was large, but those engaging in business, in agriculture, and in other pursuits, probably equalled the miners in number. The restless horde penetrated everywhere. The beautiful rounded and timbered slopes, and the enchanting parks of the Southern and Central Hills captivated many, and not a canyon, not a gulch or draw, wet or dry, was left untried.

As new discoveries were announced the restless crowd rushed with frantic haste from one new camp to another. Everyone lived at high tension, ready to desert good diggings for those that were reported better, though the promise often failed of fulfilment. From French creek a stampede occurred to Spring creek when gold was found in the latter stream, but the stampeders were scarcely fairly at work on their new claims when word came that very rich diggings had been struck on Castle creek, and away the entire lot scampered, like a lot of frightened sheep. Each fellow acted as though his whole salvation lay in getting there first. A few days later the newer discoveries on Rapid creek resulted in a similar rush from older to the newer discoveries. However, this is one of the alluring features of mining, and always will be. Two parties, more venturesome than others, made their way through the wilderness to the northward with riding and pack animals only, as no wagon could be taken through that trackless forest without great loss of time. One went into the high mountainous country in the northwestern part of the Hills, in what was afterward known as the Nigger Hill district, there being a number of negroes in the party. The other penetrated into the labyrinth of canyons, rugged ridges and peaks lying to the northward of a high mountain known as Terry peak. Both of these parties were fortunate in finding rich diggings. The one stopping north of Terry peak, known as the Gordon party, included a number of miners from Montana. One afternoon some of their horses strayed and the men, taking the trail, followed the animals along a ridge and down a small narrow gulch (afterward known as Slaughter-house gulch), into the canyon of Deadwood creek, where the horses were found and they went into camp. Notwithstanding the fact that the gulch was an almost impenetrable thicket of dead and living timber—spruce, pine, and aspen, some of the men began prospecting on the bars as was their custom. From shallow holes several feet above bedrock, few pans yielded less than 2 cents and some, with depth, as high as 50. This was better than any of them had been able to find in the gulches of the Southern Hills, and prospecting was continued with vigor, the hardy fellows sticking to the work although provisions were running discouragingly low, and they were eventually reduced to 'venison straight,' before they could renew the supply, notwithstanding the fact that they had enough gold in their buckskin sacks to have bought several tons of provisions. The pay was found better on the bedrock of the bar, and the bed of the creek was surprisingly rich. Claims were quickly staked out, up and down the creek, and a mining district formed, called the Lost Horse District, which was afterward changed to Lost District.

The news of the discovery on Deadwood spread rapidly and soon hundreds, and eventually thousands, flocked to Deadwood gulch. The first wagons to enter the gulch came in about two miles below the site of the town which was built at the forks of Deadwood and Whitewood creeks. These wagons were let down the mountain side by means of ropes of the placers, of which the following is an abstract:

"We have made locations on Whitewood, a large stream that rises on the northeast side of Terry's peak, and runs down to the Belle Fourche. Starting where the creek runs out of the canyon into the lowlands, up it to the west fork, or Deadwood, as it is called, there are no better paying mines for a poor

Deadwood, South Dakota, Looking North in 1880.

(From Darton, U. S. Geol. Survey.)

snubbed around good-sized trees. For the most part the hillsides above the town were covered with dead timber, both standing and fallen, and it was this fact that suggested the appropriate name of Deadwood for the gulch, and the town was named after it. The date of the discovery by the Gordon party was late in 1875. One of the early comers into this district wrote to W. P. Jenney a letter, descriptive

man in the Hills. The ground prospects in the creek and on the bars all the way down to bedrock, an average of about 2 cents per pan in fine gold. It is said to be the same on Deadwood. The extent of the claims on these creeks, from the foothills on Whitewood, and up Deadwood, makes a distance of 25 miles, all good mining ground. A small gulch running into Deadwood, called Blacktail, is said to be

good. These mines will certainly pay from $10 to $20 a day to the man when worked in the spring. They are easily opened, for the bedrock is not deep, like it is on Spring and Castle creeks."

This letter was written on January 31, 1876, when little more was known of the district than that gold could be found throughout the length of these streams, and that in some places it was richer than in others. Custer City, a new town of several thousand people, was all but depopulated when the news of the discoveries on Deadwood reached the place, while within a marvelously short time Deadwood became a town of over 4000 population. The Wheeler brothers located the first claim below discovery on Deadwood gulch. At that place the bottom of the canyon was from 200 to 300 ft. in width, and the depth of the gravel, from 2 to 4 ft. This claim was one of the richest on Deadwood and worked with two strings of parallel sluices, produced, it was said, over $200,000. Other claims, both above and below discovery, did almost as well, while still others proved to be disappointing, the difference being due to various causes, among them being the direction of strike of bedrock relative to the direction of the stream at that point, the character of the bedrock itself, width of the canyon bed, more gold usually being found where the gulch was wide than where it was narrow. The grade of the stream was also important, for where it was steep little gold was found, the surface of the bedrock being too smooth to hold the gold. If any were found it would be in the crevices between the various blocks. Then, too, at some places there was found an accumulation of cemented bedrock material lying anywhere from on the surface of the bedrock to several feet above it. These deposits were of local occurrence, though quite frequent for from three-quarters of a mile to a mile or more below discovery. They were formed by ferric iron which issued from pyritiferous veins crossing the creek, cementing the rock fragments into a solid rock mass. Often this material was found to be gold bearing and its upper surface constituted a good bedrock for holding any gold which chanced to be carried over it. The miners called this 'false bedrock,' after the real character of the cemented material was recognized, but generally the 'true bedrock' beneath was far richer. These facts led to some interesting episodes, reference to which will be made later.

Whitewood gulch, below its confluence with Gold Run; the latter gulch itself; Deadwood gulch and its tributaries—Blacktail, Hidden Treasure, and Sawpit, on the west side, and Bobtail and Poorman on the east side, were the richest large gulches in the entire Black Hills region, though in the Nigger Hill region some very rich, but less extensive diggings were found. All of the gulches of the former system head in the region about the Homestake belt, as it is called, and have derived their gold, either directly from the ore deposits of those schists, or, like Hidden Treasure, Bobtail, Deadwood, Gold Run, and Blacktail gulches, have cut through the Cambrian conglomerates and into the Algonkian schists beneath, being thus doubly enriched.

The early-day miners understood the occurrence of gold in the beds of the streams in the Deadwood district, and also realized the true character of the bar deposits, but they did not, at first, fully comprehend the nature of the auriferous-conglomerate deposits. One of the first of these to be worked, capped a hill on the south side of Deadwood gulch, near Central City, and was known as the Alpha mine. The gravel here was less firmly cemented in this deposit than in some of the others in the vicinity, and the deposit was naturally presumed to be a 'high bar' of Deadwood. On the opposite side of Deadwood gulch, and tributary to Hidden Treasure, were found similar deposits, some of which also resembled high bars, and like the Alpha, were presumed to be such, among them being the deposits of the Aurora, Keets, Wooley, and Picacho, though the largest deposit, in the Hidden Treasure mine, dipped northerly into the hill and was covered with quartzite, shale, and sandstone. This deposit passed entirely through the hill, outcropping again, lower down, on the south side of Blacktail gulch, in the Esmeralda and adjoining mines. Still farther northward, on the opposite side of Blacktail, what appeared to be the same conglomerate bed, could be seen capped with quartzite and 'porphyry,' and dipping into a high mountain. This was the conglomerate at the base of the Cambrian, to which extended reference has already been made. The miners could not, at first, comprehend the geology of this deposit, nor did it interest them particularly. Some thought it to be the channel of an ancient river, similar to those found in California, but the main thing was that it paid—was rich, and paid handsomely. The first mills built in the Black Hills were for treatment of these conglomerates, and a number of them were kept steadily and profitably employed for several years. This series of deposits, which had a common genesis and which at one time constituted a single sheet, had been divided in irregular patches by the erosion of the several gulches of the region and these segregated deposits constituted numerous mining claims, the most important of which were those already named, together with those on the north side of Blacktail gulch—the Gustin and Minerva, and the conglomerate deposits as a whole came to be known as the Gustin belt. The ore from some of these claims was the richest ever found in large bodies in the Black Hills. I saw slabs ripped up from bedrock in the Hidden Treasure mine that showed at least $100 in nuggets of gold, some of which were worth as high as $5, while the rock was liberally sprinkled with little pieces worth from 50 cents to a dollar. The deposit in the Gustin-Minerva section is either faulted or intersected by a mass of eruptive rock, but the conglomerate continues northward beyond this disturbance, and may be seen in the neighborhood of the head of City Creek, and along Howard gulch, on the east side of Sheep mountain, 2½ miles northwest of Deadwood. The conglomerate is here gold bearing also, but to what extent I am unable to say.

Erosion has accomplished some strange things in the vicinity of Deadwood. Just east of the town a steep mountain, capped with limestone, and known

as White Rocks, rises 1000 ft. above the bottom of the canyon. From its summit a splendid view of the surrounding country may be obtained. On every side rise high hills having either gentle slopes or rugged precipitous sides, the various formations having a controlling influence on the topography. This is shown in the accompanying illustration of the Cambrian bluff at Deadwood. Almost directly eastward and three to six miles distant, is a broad U-shaped valley, through which meanders a small stream called Boulder creek, which runs for several miles through limestone, the erosion never having cut deep enough to expose even the top of the Cambrian.

The general direction, the form, and grade of this limestone valley give it the appearance of having been, at one time, the outlet of Whitewood creek, which, in my opinion, it actually was, but the occurrence of a fault crossing the course of Whitewood creek two miles below the city of Deadwood, may be responsible for the change in the direction of the stream, for a few hundred yards above the crossing of this fault line the Whitewood takes an abrupt turn to the westward and is seen to have cut its way down through the Corboniferous, Silurian, and Cambrian, almost to the Algonkian, making a second exposure of those rocks within a distance of two miles, its bed being about 100 ft. lower than the valley of Boulder creek. In proof of this theory, it may be cited that the bed of Boulder creek and the bars along its course are wholly composed of gravel from the crystalline area of the Algonkian, though, as previously stated, Boulder creek is wholly in limestone, and so, too, are its tributaries, and this detritus from the Algonkian could only have reached its present position by way of Whitewood creek, when that stream flowed through the valley of the Boulder. Furthermore, this gravel of Boulder creek is gold bearing, as may have been suspected, when the character of the material is considered.

The activities of these early-day miners in Deadwood and Whitewood gulches and their tributaries, resulted in the prompt discovery of the great ore deposits which were the source of all the gold, both in the ancient shore-line conglomerates and in the more recent placers—stream beds and bars, alike, these latter often representing two or more periods of deposition. The Cambrian conglomerates may be considered as representing the oldest placer deposits in the world, unless conglomerates can be shown to be auriferous in some pre-Cambrian formation.

One of the first quartz-vein discoveries made in the Hills was that called the Father De Smet, named after a Jesuit priest who for years had lived among the Sioux and had endeavored to enlighten them with the teachings of the Gospel. He had also, so it was said, cautioned the Indians to say nothing of the yellow metal found in the rocks and in the stream beds, as, if it came to the knowledge of the white men, they would quickly overrun the country and the Sioux would lose their beautiful mountain hunting grounds. Father De Smet was correct, for no sooner did the white man learn that gold was to be found there than he began to appropriate the land.

Analytic Work at Copper Queen Smelter

The analytic work of the Copper Queen smelter, at Douglas, Arizona, is done under the direction of Percy Butler. The facilities are superior, both as to the laboratory building and its equipment. A large separate structure is provided, which is divided into numerous rooms, protected against dust and draught, well ventilated, and superbly lighted. The routine samples for furnace control are here determined, and also the large number of samples of custom ores are assayed and analyzed.

In making assays a preliminary 1/10 assay ton charge on all unknown ores is run in order to work out the appropriate flux. The amount of nitre (KNO_3) required is determined by multiplying the weight of the button obtained by 5, subtracting 22, and dividing the remainder by 4½. This gives the grams of nitre needed for the excess of sulphur, so that the resulting button shall weigh 22 gm. When the sulphur is high silica is added, and if the silver content is suspected to be high, borax is introduced to insure an acid slag. If much copper sulphide be present an excess of PbO is provided. Every ore is assayed in duplicate, two assays each being made of the original and of the duplicate sample. Unless three of these agree within the limits of experimental error new samples are taken and re-assayed. The charge in the crucible is always covered with a non-reducer, which consists of bicarbonate of soda 8 parts, potassium carbonate 8, and raw borax 4. Part of the above is also mixed with the charge. The reducer used consists of the same flux containing an addition of 4 parts of flour. A typical charge for oxidized ores is as follows:

Ore	½ A. T.
PbO	76 gm.
Reducer	8½ "
Non-reducer	17½ "

This is mixed and covered with 8 gm. of non-reducer. The oxide ores may be represented by the converter lining used, which shows on analysis:

	Per cent.
Silica	80 to 85
Iron (FeO)	3
Alumina	3
Lime (CaO)	1
Copper	± 2

The sulphide ores have the following approximate composition:

	Per cent.
Silica	26
Fe (metallic)	28
Lime (CaO)	2
Sulphur	22 to 23
Alumina	6

A normal assay charge for these ores is:

	Grams.
PbO	100
Non-reducer	17½
Silica	4
Nitre	13
Cover of non-reducer	8

By using an excess of PbO (from 100 to 120 gm.),

with nitre in correct amount to give the required button, enough copper can be driven into the slag, even if as much as 10% Cu be present, to give a button which on cupellation will yield a nice feathered litharge, reducing the absorption and keeping the volatilization very low. A comparatively soft cupel is used. Cupellation is begun at a low temperature, feathering from the start, and this continues until it is close to the button. The finish is made at a high temperature. Dry-wood blocks are placed in the muffle-mouth to open the button after melting. The heat is carefully regulated throughout, oil being used as fuel.

The determination of gold and silver in the copper bullion is done as follows: one assay ton in duplicate is weighed into a 16-oz. beaker, and 20 c.c. of a solution of mercuric nitrate is added. This is made by weighing 20 gm. of mercury and dissolving in 8 c.c. of HNO_3; it is boiled until neutral, so that a small amount of basic nitrate of mercury will precipitate on the addition of water. This is made up to 2200 c.c. with water. Take 25 c.c. of this with a pipette, and cover the bullion with it. This amalgamates the bullion. Add 80 c.c. of strong H_2SO_4 and boil to fuming. The copper goes into the solution and the gold and silver remain undissolved. Take up the copper sulphates with water, and when partly in solution add hot water. To collect the gold and silver add a small portion of lead acetate solution, and before filtering add 1 drop of HCl+Aq, half and half, as a precaution. Filter through double paper, and scorify the paper with test-lead and borax, aiming at an 18-gm. button, which is then cupelled. The results are from 0.04 to 0.08 oz. per ton higher by this sulphuric acid method than are obtained with the old nitric acid method. The copper bullion samples are taken by saw-cuts from a sample pig poured from each converter charge. The saw-cuts are made by a horizontal band-saw, in opposite directions, extending a trifle over half-way through the bar, the cuts being a fraction of an inch apart.

From the blast-furnaces come two samples daily, namely, a slag and a matte sample. These are composites, that is, they represent the day's run on all furnaces. There is also a 24-hour sample of slag and matte, which is of large size, and is sent to the sampling works for reduction. The analysis of the slag and matte samples is finished and reported within 1½ hours, the substances determined being silica, iron (FeO), alumina, and lime (CaO). The caustic soda method is used for the alumina.

The slag analysis is made as follows: ½ gm., finely ground in an agate mortar, is weighed into a small casserole. It is just wetted with water, a pinch of $KClO_3$ added, and 1 to 1½ c.c. HCl dropped on while agitating the casserole and stirring with a glass rod. It will gelatinize in one minute. It is then evaporated to dryness. This is dissolved with HCl and water, and filtered through an ashless filter paper with quick suction. It is dried, ignited, and the SiO_2 weighed. The filtrate is treated with a slight excess of ammonia and 3 gm. ammonium chloride; the solution is boiled and filtered. The CaO is determined in this in the usual way. The precipitate of ferric and aluminum hydrate is washed by a small jet of water into the original beaker, and 1½ inch of stick caustic soda (Baker's C. P. by alcohol) is boiled in it for 3 minutes. The alumina goes into solution as sodium aluminate. It is filtered through a double filter to retain all the iron. The filtrate is acidified with HCl, and a slight excess of ammonia (determined by phenol-phthalein) with 3 gm. of ammonium chloride, are added; the solution is boiled five or six minutes, and then filtered through a double filter using one ashless paper (No. 589 S. & S.) and one ash paper No. 597. The precipitate on the filter is washed three or four times, then dried and ignited, and the Al_2O_3 weighed. The iron is dissolved through the paper with HCl and titrated with bichromate of potassium, after reducing with stannous chloride and taking up the excess of stannous chloride with mercuric chloride. The time required is 1 hour and 5 minutes.

A GLIMPSE OF THE COEUR D'ALENE

We are indebted to A. E. Robinson for the characteristic view of Coeur d'Alene scenery shown below. The high mountain in the middle is Kellogg Peak near Wardner. Near the lower left-hand corner are the surface workings of the Sullivan, and the ridge in the foreground is partly covered by the Stem-

winder workings. The Bunker Hill claim extends from near Milo creek, in the bottom of the canyon, to the right between the Stemwinder ridge, and the ridge covered with timber lying beyond. The Wardner foot-wall outcrops at a point near the lower Sullivan workings, and runs through the point from which the picture was taken. Numerous traverse and other survey lines can be seen. The peak is almost due south of the point of observation.

Hoisting is done in a mine at Guanajuato, Mexico, in a shaft over 1750 ft. deep in which there is not a stick of timber. The guides are steel hoisting cables fixed at the surface and drawn tight on jack-bars at the bottom. As a matter of course, there is tremendous vibration in these guides, when the bucket is in motion in either direction, but no accidents are reported as a consequence of this. Here is ease for the exercise of ingenuity in the tying of these rope-guides to the rock-walls, while not interfering with the passage of the buckets.

British Columbia Mining, 1909

*The value of the mineral output of British Columbia for the year 1909 amounts to $24,443,025, which, while less than that of 1906 and 1907, is still considerably greater than that of any previous year. The tonnage of ore mined, exclusive of coal, was 2,057,713 tons, a decrease from that of 1908 of 25,893, or 1.24%. This was produced by the various districts in the following proportions: Yale Boundary mines, 71.03%; West Kootenay, Rossland mines, 11.55%; East Kootenay, mines in Fort Steele division, 7.28%; Coast, 1.92%; all others, 8.22%. The number of mines from which shipments of ore were made was 89, and of these only 52 shipped more than 100 tons each during the year, while but 32 shipped in excess of 1000 tons each. Of the latter eight were in Nelson mining division, 5 in the Boundary, 5 in Ainsworth, 4 in the Slocan, 3 in the Coast, 3 in Trail Creek (Rossland), 2 in Fort Steele, and one each in Trout Lake and Queen Charlotte divisions.

TOTAL MINERAL PRODUCTION FOR ALL YEARS TO 1909, INCLUSIVE

Gold, placer	$70,673,103
Gold, lode	55,277,687
Total gold	$125,950,790
Silver	29,850,586
Lead	23,259,255
Copper	55,871,893
Other metals	890,699
	$235,823,223
Coal and coke	102,904,261
Building stone, brick, etc	9,093,100
	$347,820,584

QUANTITY OF MINERAL PRODUCTION FOR 1908 AND 1909.

	1908		1909	
	Quantity.	Value.	Quantity.	Value.
Gold, placer	.....	$647,000	.....	$477,000
Gold, lode	255,582	5,282,880	238,224	4,924,090
Total gold		$5,929,880		$5,401,090
Silver, oz.	2,631,389	1,321,483	2,532,742	1,239,270
Lead, lb.	43,195,733	1,632,799	44,390,346	1,709,259
Copper, lb.	47,274,614	6,240,249	45,597,245	5,918,522
Zinc	.....	270,000	.....	400,000
		$15,394,411		$14,668,141
Coal, tons 2240 lb.	1,677,849	5,872,472	2,006,476	7,022,666
Coke " " "	247,399	1,484,394	258,703	1,552,218
Other materials	.....	1,100,000	.....	1,200,000
Total production		$23,851,277		$24,443,025

The number of men employed were: In metal producing mines, 3037 (2048 below and 989 above ground); in mines not shipping, 217 (136 below and 81 above ground); total, 3254. A mine employing say 12 men for 4 months was credited with an average of 4 men for 12 months, so that the total above given is less than the actual number of men who worked in the mines during the year. The number employed at the coal mines was 6418, including 215 white boys, and 672 Chinese, Japanese, and Indians. The official figures of all employed at the mines of the Province, therefore, give a grand total of 9672.

PRODUCTION OF MINERAL BY DISTRICTS AND DIVISIONS.

Districts.	Divisions. 1908.	Divisions. 1909.	1908.	1909.
Cariboo district			$405,000	$247,000
Cariboo mining division	$355,000	$220,000		
Quesnal mining division	30,000	12,000		
Omineca mining division	20,000	15,000		
Cassiar district			298,234	234,498
East Kootenay district			4,802,680	4,766,215
West Kootenay district			5,448,224	5,169,749
Ainsworth mining division	422,181	617,340		
Nelson mining division	462,836	584,955

Similkameen and Nicola divisions	101,583	225,210		
Yale mining division	3,000	2,000		
Coast districts (Nanaimo, Alberni, Clayoquot, Quatsino, Victoria)			5,233,397	6,280,631
Totals			$23,851,277	$24,443,025

The coal produced was mined chiefly by three companies, the Wellington Colliery Co. and the Western Fuel Co., both on Vancouver island, and the Crow's Nest Pass Coal Co., in southeast Kootenay. These companies produced about 88% of the total coal mined. Of the smaller collieries, those on Vancouver island were the Pacific Coast Coal Co.'s mines, with about 70,000 tons, and the Vancouver-Nanaimo, 10,000 tons; in Nicola valley the Nicola Valley Coal & Coke Co., 62,000 tons, and the Diamond Vale Co., 1700 tons; in the Crow's Nest district, the Hosmer and Corbin collieries each produced about 60,000 tons. The gross output of coal was 2,400,600 tons (of 2240 lb.), of which 998,494 was sold for consumption in Canada, 741,648 exported chiefly to the United States; 260,554 burned under colliery boilers; 394,124 used in making coke, and 5782 tons added to stock. The quantity of coke made was 258,703 long tons, of which 210,884 was for consumption in Canada; 40,620 exported, nearly all to the United States, and 7199 added to stock. The production of coal was the largest for any year since coal mining was commenced in the Province; that of coke was second only to that of 1905, when 271,785 long tons were made.

Production of placer gold was $477,000, as against $647,000 in 1908, and this was the smallest amount of any year since 1894. The decreased output was attributable partly to the short water supply last season. The value of lode gold was $4,924,090, a decrease of $358,790, as compared with 1908. Nelson, Boundary, and Coast districts each produced more lode gold, but the decrease in Rossland camp was larger than the total increases of other parts of the

*Advance excerpt from the 'Report of the Minister of Mines for 1909.'

Province. About 86.5% of the lode gold was recovered from smelting copper ores; the remaining 13.5% was from stamp-milling. The stamp-mills operated last year were those of the Hedley Gold Mining Co., at Hedley, 40 stamps; Granite-Poorman mill, near Nelson, 20 stamps; Queen mill, at Sheep Creek, 20 stamps; Nelson division and one or two small mills also in the last-named camp.

The silver produced totaled 2,532,742 oz., a decrease in quantity of 98,647 oz., and in value of $82,213, as compared with 1908. About 98.2% was from silver-lead ores and the remainder from copper-silver ores. The Slocan district, including Ainsworth, Slocan, Slocan City, and Trout Lake divisions, produced about 50% of the total, and Fort Steele division of East Kootenay 23%, all from argentiferous galena ores.

Lead showed a production of 44,396,346 lb., this being an increase of 1,200,613 lb. in quantity, and $76,460 in value over that of 1908. Mines in Fort Steele division, chiefly the St. Eugene, produced nearly 61% of this total; those in Ainsworth and Slocan, 34%, and in Nelson and Trout Lake divisions, 5 per cent.

The amount of copper, placed at 45,597,245 lb., was less in quantity by 1,677,369 lb., and in value by $321,727. These figures do not take in account smelter charges or deductions, but show the copper contained in the ore smelted. There was a slight increase in the Boundary and Nelson divisions, but a heavy falling off in Rossland and the Coast districts. The proportions of production of districts were: Boundary 89.04%, Rossland 7.70, Coast 2.84, and Nelson 0.42%. The average assays of copper in ores of the several districts, based upon copper recovered, were: Boundary, 1.41%; Coast 1.5, and Rossland 0.75 per cent.

No iron ore was shipped and very little mined, there having been no market in 1909 for iron ore from the Province. About 10,000 tons of zinc ore and concentrate was sold in 1909, the zinc content ranging from 38 to 48%. The Lucky Jim was the only mine that shipped zinc ore; it sent out 4700 tons averaging 48% zinc. The Whitewater group, Ainsworth division, produced 4600 tons of zinc concentrate, also containing silver from 15 to 25 oz. per ton. Mills of other mines also produced zinc concentrate, but little of that production was sold.

In building materials, etc., the chief production was in granite and sandstone, brick, pottery, and portland cement. Of the last, 238,000 bbl., valued at $360,000, was manufactured on Vancouver island.

Prominent features of the annual report, other than the statistical tables and accompanying comments on the year of the provincial mineralogist, Wm. Fleet Robertson, are: Accounts of that official of his personal observations in several mining districts—Queen Charlotte islands; the coal mining district in the Crow's Nest country in which there has been much development and production; the important though undeveloped coal areas in the upper Elk River district, computed by D. B. Dowling, of the Geological Survey of Canada, to have an area of 140 sq. mi., and a probable coal content of 100,000,000 tons per square mile; the mineral region in East Kootenay, lying between the Canadian Pacific main line railway, in the north, and the Moyie Lake district, along the Canadian Pacific Railroad Co.'s Crow's Nest branch, to the south; and the Duncan River district and Sheep Creek camp, both in West Kootenay. Several official reports on the explosion at Extension colliery, Vancouver island, in which 32 men lost their lives last October, and diagrams also form part of the Annual Report: Well printed halftone reproductions of photographs are numerous, and some of these are of especial interest, since they illustrate mining and other scenes not previously used in any official report.

WORKING COSTS OF GOLD DREDGING IN CALIFORNIA

By Charles Janin and W. B. Winston

In California, dredging companies determine yardage handled by bank measurement ahead of the dredge. When dredges are working in swift running rivers, as in some foreign countries, it is difficult to determine the yardage handled with the same degree of accuracy that can be computed from careful bank measurement; the method generally employed in such cases is to count the number of buckets dumping within a stated time, making some allowance for buckets only partly filled. Should too large a yardage be figured, it is obvious that the estimated cost per cubic yard will be proportionally too low. Working cost cannot be fairly used in comparison unless uniform methods of determining them are employed, and also unless operating conditions are somewhat similar. Ground in the same locality often varies to such an extent that dredges similar in construction, design, and bucket capacity, and operated under the same management, show at times considerable difference in cost per cubic yard. Nearly all dredging companies operating in California keep careful daily records, though on the dredges owned by individuals the practice of keeping exhaustive records of yardage handled and the segregating of items of working cost is not always followed. It may also be said that in some cases working cost is in a great measure a matter of bookkeeping.

The table opposite showing the operating cost per cubic yard for dredges of different capacity, working in California, has been compiled from records of various dredging companies, with the endeavor to arrive at the total operating cost per cubic yard with some degree of accuracy. The buckets in use in California vary in capacity from 3 to 13½ cu. ft. and will probably soon be made 15 cu. ft. Dredge operators in California prefer the close-connected bucket line to the open-connected type, and the use of digging spuds, to head-lines. In practice the close-connected bucket line dumps at the rate of from 18 to 22 buckets per minute, while the open-connected line averages from 12 to 14 buckets per minute. On some of the older boats where the bucket line has been changed from open to close-connected buckets, it is claimed that the yardage handled has been nearly doubled and the expenses per cubic yard decreased.

[1]Total possible time in year's work, 8784 hours.
[2]Including general expense, management, etc.
[3]Heavy repair cost due to new tumbler, conveyor belt, repairs to digging ladder, screens, etc.
[4]Replacing tumbler shafts, conveyor belt, and new screen included in repairs.
[5]New steel spud and screen in repairs.
[6]Depreciation charges included in total expense.
[7]A 7-ft. dredge is now working this ground at a profit.
[8]This dredge successfully replaced an open-connected bucket dredge which could not handle ground at a profit.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Crushing by Stages

The Editor:

Sir—Most millmen have practised crushing by stages, but not in stamp-mills alone. Every machine has its sphere of usefulness, or its limitations. The rock-breaker of different sizes, for breaking ore between certain sizes, depending upon the physical character of the ore; the stamp-mill for other sizes and the pulping machines, such as Chilean or Huntington and tube-mills for still other sizes. Stamps of weights between 850 and 2000 lb. approach at both ends the limits where the rock-breaker or the fine-grinder is more efficient. The 2000-lb. stamp approaches the rock-breaker, while the 850-lb. stamp comes near the sliming machine. While the complication of machinery would no doubt be profitable in very large mills, for the average small mill it would be out of the question. That portion of the mill where the most expensive grinding takes place (the fine grinding plant) is where this principle might be better applied.

F. Cremer says the mining fraternity is slow in recognizing the efficieney of the prineiple as illustrated in the conical tube-mill. Maybe the mining fraternity has found the weak points of the conical tube-mill and prefers two cylindrical tubes, sizing between, or crushing in stages instead of in one machine. Mr. Cremer will do a favor if he will point out in what partienlar the conical tube-mill is more efficient than cylindrical tubes. My idea is that the conical tube has its limitations, just as the stamp-mill has, and for fine grinding, from 100 to 200-mesh, the cylindrical machines properly proportioned are superior.

If in a 5-stamp battery each of the stamps were of different weight and ran at different height of drop and different speed, we would have the same principle as in the conical tube-mill, less the sizing action. The heavy stamps would do most of the work, as is the case in the larger diameter of the conical tube. The question is, to what extent does this sizing action take place. We know that on dry ore with no discharge of ore from the mill, the sizing action of pebble and ore particles is pronounced, but how far does this take place in wet crushing, where a continuous stream is entering and leaving the mill? The pebbles size, of course, but does the ore size, or do the small pebbles have to work on large particles of ore? If so, the principle that Mr. Cremer favors is not found in the conical tube. My experience is that this sizing action on the ore is very imperfect and consequently the small pebble, with its comparatively small amplitude of fall, is in the position of an 850-lb. stamp, taking the size of ore that had better go to the rock-breaker.

ALGERON DEL MAR.

Fort Bidwell, California, July 20.

Lining Old Mill Mortars

The Editor:

Sir—Stamp-mill mortars that have not been provided with 'liners' in the original design, may be lined with cast-iron plates ½ in. to 1 in thickness, or if there is not enough room between the stamp heads and the sides and ends of the mortar box, sheet steel ¼ in. thick, may be cut to the proper size and shape, and set in the mortars, thus saving the mortar casting from further wear by abrasion. To accomplish this it may be necessary to change the position of the stamps by substituting guides which bring the stamps closer to each other. If ¾-in. clearance between stamp heads can be secured it will be found sufficient, if the guides hold the stamp stems vertically, permitting but little 'play,' for if too loose there is danger of a falling stamp striking one that is being lifted—a thing to be avoided at all times. An additional advantage is gained by increased capacity per stamp if the dies are slightly larger than the shoes, that is, have a greater diameter. This difference should not exceed ½ in., however, or the die is likely to cup badly, thus decreasing, rather than increasing, capacity. To get the best results in stamp-milling the cam-shaft boxes must be carefully lined up, whether babbitted or not, or the shaft will 'jump' with every revolution, and if the boxes be babbitted the condition will be worse than where no babbitt is used, for the shaft will quickly pound the metal to pieces and the fragments are more than likely to fall down into the mortar, and every millman knows the results that follow the introduction of lead and antimony compounds into the stamp-mill mortar.

San Francisco, July 20. MILLMAN.

Cyaniding Sulphides

The Editor:

Sir—There is a subject about which little or nothing has appeared in the technical press. I refer to 'Cyanidation of Sulphides'; and should be pleased to gain some data. It would be a boon to the mining world if those who have been engaged or are at present engaged in treating sulphides, you might say pyrite, by cyanidation would diffuse some knowledge on the subject by giving their experience. There is ample room, I think, for a few articles on the subject, describing fully the kind of sulphide treated, time of contact, strength of solution, aeration, and methods of precipitation. There are some plants in California and Nevada treating their sulphides at home, and information regarding their experience would be useful to those now undertaking the task, as sulphides treated and difficulties to overcome elsewhere may be similar. Instead of shipping to smelters, the treatment of the baser products at home is becoming more in vogue. In most cases it is cheaper, especially at a mine having a cyanide plant. Again, it solves the difficulties and expense of transportation. Any information that may be given from whatever clime will not only add to metallurgical knowledge, but will be greatly appreciated.

INGENIERO KCN.

San Francisco, July 19.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Coolgardie is derived from a native word, 'Golgarda,' the name of a pool of water, the one native well in the vicinity of the famous gold deposits. Kalgoorlie is from 'kalgorlah,' the native name of a fruit growing in the locality.

When several charges of dynamite are to be exploded simultaneously by electric fuses, it is necessary, unless the electric fuse wires are long enough to reach between the drill-holes, to join them with insulated copper connecting wire.

The coefficient of friction at low journal speeds is high, but decreases as speed is increased. It varies approximately as the square root of the speed. Also, friction is much greater at low, or ordinary temperature (60°) than at 100° or more.

The Parkfield district of California, situated in the Cholame valley, between the Mount Diablo and Temblor ranges, is connected with the San Joaquin valley at its junction with Antelope valley, and is fourteen miles south of Coalinga. Wild-cat oil wells are being drilled in it.

The only advantage in employing a 48-in. 'drum' on a gravity tramway, in place of one 36 in. diam. is that the cars may be more readily controlled by brake with the former than the latter. It is also somewhat better for the rope, as it will not make so short a bend.

Steel in various forms has been employed in mines for the support of roofs, old T-rails having frequently been used for this purpose years ago. Generally steel I-beams have been used in this way, until now, special forms of the I and channel type are made for use in mines.

Gold in a stream will not lodge where the fall of the stream is heavy, that is, much over 100 ft. per mile. In such instances the rapid current carried along all of the detritus, gold included, generally leaving the bedrock smooth and hard. If gold has passed over such a place, it will lodge only in crevices down into which it sometimes works to the depths of several feet. When heavy grades are met in an auriferous stream, prospective investors would do well to use much caution.

Deposits of high-grade soda exist in various places in Wyoming in the beds of dry lakes or ponds. They range from a few feet in diameter to some that cover several hundred acres. Most of these alkali deposits, though lying at different elevations above the sea, seem to have a common origin and occur in all parts of the State. In some localities the amount of alkali stored in clays and shales is enormous. For example, in the midst of the Red desert there are clay beds of a dull red color which have rather a pulverulent surface during dry weather, though a few inches below the surface in many places the alkali amounts to 30 or 40% of the mass. When there is a slight rainfall the clay forms a protective covering and little of the alkali is carried away.

Tests of rain gauges are being conducted at Ithaca by the New York State Water Supply Commission, and show that the difference in registration between different types is not great. If the registration of a U. S. Weather Bureau gauge is called 100, Walter McColloh, chief engineer of the Commission, reports that the registration of a Smithsonian gauge on the ground will be 101.7, that of a Fuertes gauge 102.1, that of a Dewitt conical gauge 98.4, that of a Smithsonian gauge 10 ft. above ground 105.2, that of a Fuertes gauge 10 ft. in the same position 104.3, and that of a Dewitt conical gauge 96.6.

Tungsten filaments are commonly made by mixing the metal in a paste that is then extruded in the form of a filament, after which the paste is expelled and the particles of metal are welded together by an electric current. This complicated method is due to the fact that tungsten is not sufficiently ductile to be drawn out into fine filaments. An English concern has just discovered a method of producing drawn filaments of tungsten, and the General Electric Co. has also just announced the discovery of a method by which tungsten may be rendered sufficiently ductile to permit of its being drawn into fine wires. The drawn tungsten filament is stronger than the filament made by the sintering process.

In the Lehigh Coal & Navigation Co.'s property near Summit Hill, Pennsylvania, a fire has been burning continuously since February 1859, resisting all efforts to extinguish it. It was finally determined to cut a channel through the coal from floor to roof of the coal-seam, which is 50 ft. thick, and to fill the cutting with clay. This barrier will probably stop the further advance of the fire, as there will be nothing for it to feed upon. In Wyoming, on Powder river, coal veins are burning which have been on fire as far back as the oldest explorers of the region have any knowledge, and these subterranean fires have burned out a vast area, turning the clay shale to hard jasper, and making of the surface a veritable desert —bad lands.

Exhaust of pumps operated by compressed air will not ordinarily freeze if the air outlet be of large size, but often pumps which have been designed for operation by steam are connected with the compressed-air line, in the mine, and such pumps are more than likely to freeze at the exhaust. This can be prevented if the main water-discharge column be tapped about 10 ft. above the pump and a ¼-in. pipe be inserted, this small pipe to be extended to the air exhaust of the pump, and the end of the pipe drawn down to about one-sixteenth inch. The jet of water from this little nozzle should be directed into the exhaust opening, when it will be found that the exhaust will not freeze. In some cases it is sufficient to allow the stream of water from the little pipe to merely drip down on the exhaust port of the pump. If this latter fails to prevent the pump freezing the former method will not.

Special Correspondence

LONDON

Coal Dust Burner. — New Einasleigh Mine.—Talisman.— Great Boulder.

Many attempts are made from time to time with the object of using coal dust for steam-raising purposes. There are two reasons why such a method of combustion is advantageous; first, the air is more efficiently mixed with the coal, and second, fuel that has hitherto been wasted, can be utilized. Many practical difficulties have stood in the way of success, chiefly the production of too high temperatures locally. The design of the Bettington-Robeson boiler which is now being introduced in England and South Africa, diminishes these disadvantages. It is of the vertical type and consists of top and bottom drums connected with three sets of vertical tubes arranged in concentric rings close together. The central, upright, cylindrical space is wide and a lining of firebrick is built against the inner set of tubes. The burner is at the centre at the bottom and the current of dust and air on ignition flows direct up the centre and impinging on the top drum turns toward the outside and travels downward in contact with the firebrick. On arrival at the bottom it passes below the firebrick and comes in contact with the tubes for the first time. It travels up by the inner set and down again in contact with the outer set and finally the gases are discharged through an economizer for heating the feed-water and subsequently through a heater for heating the air fed to the burner. The inside lining of firebrick is intended to protect the first tubes, which in their turn abstract heat from the brick and prevent it from melting. The burner is also water-jacketed and the water circulating through it is used as feed. The heat obtained is so great that the ash of the coal falls in a molten condition. The pulverizer and fan are one and the same machine, the coal being fed through a hopper and pulverized by the blades of the fan. The air and dust first go into a chamber where the coarser particles of coal settle and then through the heater and on to the burner. The blades of the fan can be regulated so as to vary the amount of air drawn in. The draught through the boiler is supplied by this fan and the height of the chimney is determined solely with a view of getting rid of the products of combustion.

The New Einasleigh copper mine in Queensland is turning out to be a valuable property. The mine is owned by an English company which was formed in 1907, and the control is with the same group as British Broken Hill, W. H. Woodhead being the leading spirit. The development has been devoted to opening the third and fourth levels. At the third level a cross-cut was driven, and intersected the lode at 254 ft. The vein was here found to be 47½ ft. wide, averaging 8% copper. A drift to the north passed through 88 ft. of ore and then opened a faulted zone. Subsequently the lode was found again and as driving was continued the content gradually increasing to 8½%. By diamond-drilling at the end of the working it was shown that the lode was 61 ft. thick averaging 6% copper. A south drift on this level was carired 75 ft. through 6½% ore and at a point 30 ft. from the cross-cut a winze was sunk 90 ft. in ore of the same grade. On the fourth level the lode was intersected at 324 ft. from the shaft and was found to be 30 ft. wide averaging 9%. A north drift passed through 30 ft. of 8% ore, and a south drift after passing through broken country found the lode, exposing ore which averaged 7% copper for 37 ft. The manager has estimated that the ore reserve on January 31 was 141,500 tons, half of it averaging 8% and half 4%. A recent cable announces that additional ore estimated at 77,000 tons had been developed, bringing the total reserve to 218,500 tons. In order to test the smelting qualities of the ore 15,000 tons was sold to the Chillagoe company. By this sale the development expenses have been met. A concentrating plant capable of treating 150 tons per day has been built. This includes a unit of Elmore vacuum plant and Wilfley tables which are to be tried against each other on the fine portions of the ore. The directors say that the cost of treatment of the former will be greater than that of the latter, but at the same time the recovery will be higher.

The Talisman is a gold mine situated near Karangahake, in the Province of Auckland, New Zealand, and is managed by Bewick, Moreing & Co. Dividends were first paid in 1906 when £30,000 were distributed. During succeeding years the dividends have been £60,000, £90,000, £108,750, and £120,000, showing a satisfactory progress in profits. The latest report discloses a most encouraging state of affairs, due to the discovery of high-grade ore in the lowest level. During the year ended February 28, the 50-stamp mill treated 44,800 tons and the yield by amalgamation and cyanidation was 46,553 oz. gold and 234,200 oz. silver, being over 1 oz. gold and 5 oz. silver per ton, and an extraction of 95% of the gold and 75% of the silver. At the beginning of 1910 three tube-mills were started,

but defects in their construction have prevented them getting to regular work. During the last two years many new additions have been made to the plant, among which pumps for coping with the great inflow of water take a prominent part. The cost has been provided so far out of revenue, and it is the intention of the directors to provide further funds for capital expenditure by issuing 45,000 new shares at 25s. each. The figures for reserve on February 28, given in the engineer's report, have been rendered out of date by subsequent discoveries on the thirteenth level. At the meeting of shareholders the chairman announced that recent discoveries had disclosed ore with average content above that of the ore treated during the past year. The orebodies are variable and their value difficult to estimate, as the figures vary from ½ to 500 oz. The mine appears to have several prosperous years before it.

The Great Boulder Proprietary undoubtedly deserves to be called the premier mine of Western Australia and during the 15 years of its life has produced gold worth more than £6,500,000. The report for 1909 shows that 187,755 tons of sulpho-telluride ore was treated in the stamp-mill, yielding by amalgamation bullion valued at £227,317; and by cyanidation bullion valued at £366,366, a total of £593,-683. The costs were as follows: development £38,329, amount developed 207,406 tons at a rate of 3s. 8d. per ton;

mining £82,143 or 8s. 9d. per ton of ore mined; milling and roasting £83,783 or 8s. 11d. per ton; cyaniding £32,955 or 3s. 6d. per ton; general charges and sundries £12,776; bringing the total cost to £248,382 or 26s. per ton. These tons are of 2240 lb., so the working cost per 2000 lb. is 23s. Office expenses in London and Adelaide absorbed £10,010, taxes £29,100, and depreciation £45,000; £262,500 has been distributed as dividend. The ore reserve on December 31 was 751,077 tons, averaging 16 dwt. which is 1 dwt. more than the content of the ore treated during 1909. The main shaft is now down 2599 ft. and the Edwards 2557 ft.; they have been connected at the 2350-ft. level. The richest ore in the present reserve is in the 2200-ft. level, the average being 25 dwt. and the ore in the 2350-ft. level is as good as any found in the 1000-ft. above with the exception of this rich ground. The two most important developments on the 2500-ft. level are blocks 51 ft. long of 12 dwt. ore 5 ft. thick, and 54 ft. of 13 dwt. ore 5 ft. wide in the north and south drifts from Edwards shaft. This is a better result than on the 1600 to 2050-ft. levels, where the average has been only 11 dwt. The amount of ore in hand is sufficient to last for four years, and the prospects for further discoveries seem to be good.

BUTTE, MONTANA

Output of Mines.—Heinze Properties.—Ophir.—Parrot Suit.

There has been a great deal of misstatement published about the curtailment of production at the Butte mines. As was stated in these letters a few weeks ago, the curtailment consists of a reduction of ore output amounting possibly to 500 tons per day, made necessary by the purchase of the Clark mines by the Anaconda and the closing of the Clark smelter in Butte. The two Anaconda smelters have not sufficient capacity to handle all the ore that can be mined, or that has been mined for some time. At some of the mines a Sunday rest day has been given the men and this announcement prompted some of the papers to announce that operations at all the mines had been reduced to five days per week. It is announced officially that the Anaconda smelters have been operated at full capacity. The actual curtailment so far has been equal to about the former production of the Clark mines. It is admitted that there may be a further reduction of output if necessary, but at present it is not contemplated. The contract for the construction of the tramway from the Colorado mine of the Davis-Daly company to the Northern Pacific railroad tracks has been signed, and workmen are engaged in work preliminary to putting down the rails. M. W. Brown, general manager for the Heinze company, says that active mining ought to commence in the Colorado in about one month. It is stated that 500 tons of ore per day will be shipped to the Heinze concentrator at Basin as soon as the tramway is in condition to allow the ore being run over the line. Mining men who have been in the Colorado declare that large quantities of high-grade ore have been blocked out on the 1200, 1400 and 1500-ft. levels, the value running about 6% copper with some silver. The Ohio Copper Co. is producing at the rate of about 8,000,000 lb. of copper per year, and if F. A. Heinze is successful in arranging his refinancing scheme in Europe, the mill will be completed and fully equipped, whereas, at present only about one-half the mill is in shape to handle ore. Mining is now being carried on at 50c. per ton and concentrating costs 40c. per ton, these figures also including the cost of management and incidental expenses. The Ohio has a floating indebtedness of $600,000 with outstanding bonds amounting to $1,246,000, convertible into stock at par, while there are bonds in the treasury amounting to $754,000 and it is the sale of these Mr. Heinze is now endeavoring to effect in Europe. W. L. Credon has commenced an examination of the silver ore reserves in the Ophir mine of the Butte Central Copper Co., and upon the result of this examination will depend whether the company will erect a mill to treat the ores now on the 200, 300, 400, and 500-ft. levels. These ores are said to be rich in silver and if Mr. Credon so decides the mill will be built as it is contended that the silver will not only pay the operating expenses, but will leave something for the treasury. A force of men is now at work in the Ophir and sinking to a depth of 1500 ft. will soon be commenced. After two continuances the case of the minority stockholders against the Parrot Mining Co., for an appraisement of the stock, has been set for hearing on September 12. Under the laws of Montana minority stockholders have a right to ask for an appraisement, the expense to be paid by the company. The Butte-Ballaklava company is sending a little over 200 tons of ore per day to the smelter which is averaging 16 tons of copper besides a high value in silver. High-grade ore is still being found. The initial dividend of 50c. is payable August 1. The Silver King, one of the Davis-Daly mines, is being developed by lessees through a new shaft. This is down 125 ft. and at that depth the Silver King vein has been cut. The width has not been determined but driving has been started on the foot-wall where the orebody has been opened to a width of 7 ft. The drift has been extended about 100 ft. and the assays run from 3½ to 4% copper and about 12 oz. silver. Some assays run as high as 30 oz., the silver value being variable.

There is a possibility that the Barnes-King Gold Mining Co.'s property which was closed down a short time ago, will be re-opened by lessees. It is stated that the officers of the concern are negotiating at the present time with a view to leasing the property and that everything looks favorable for the plans to be carried to a successful issue. It is more than likely that just as soon as the negotiations are satisfactorily arranged a stockholders' meeting will be held to ratify the arrangements. Robert C. Davis, superintendent for the Iron Mountain Tunnel Co., reports the discovery of a new outcrop of rich ore near the top of the mountain on the Iron Mountain claim. The outcrop is three feet wide and chunks of the ore have been assayed showing 50% lead and 30 oz. silver per ton. Mr. Davis estimates that the new vein can be reached by extending the adit at the 1600-ft. level a distance of about 500 ft. Samples of the ore have been tested by the General Engineering Co. of Salt Lake, which is drawing the plans for the alterations in the mill in accordance with the requirements indicated by the tests. The plant is to be increased to a capacity of 150 tons per day. Mr. Davis says the market product of concentrate will assay 72% lead and 60 oz. silver. Tuolumne is mining ore as usual and shipping 100 tons per day to the smelter in Anaconda. While the papers in connection with the application for an injunction by the North Butte company have been served on the Tuolumne president, nothing further has been done and no time has been set for the hearing of the case. The East Butte Copper Mining Co. has filed a petition in the district court asking permission to turn over the money to the clerk of the court now claimed by W. O. Clymo and the Anaconda Copper Mining company. The amount involved is $2494.45, the net value of ore from the Ticon mine, the ground being in dispute between the Ticon and the Anaconda companies.

WASHINGTON

Coal Mine Accidents.—Iron Ore Production.

That the work of the Technologic Branch of the Geological Survey, now the Bureau of Mines, is beginning to be felt in a reduction in the number of deaths in the coal mines, is apparent from a report by E. W. Parker, the statistician of the Survey. He gives the number of coal miners killed in the United States in 1909 as 2412, as against 2450 in 1908. The figures for 1909 are really better than they appear on their face, for Mr. Parker has added this year three States which did not furnish fatality figures for 1908. There were 33 deaths in these States, which deaths should be subtracted from the total of 1909 if the figures are to be compared with the previous year. Also this year there was a 10% increase in the production of coal for 1909 over 1908. To show that real progress has been made in the investigation of the causes of mine

disasters, the best comparison is the number of tons of coal mined for each life lost. In 1907, when 3125 men were killed in the coal mines, 145,471 tons were mined for each life lost. In 1908, with 2450 miners killed, 167,545 tons were mined for each life lost. In 1909, with 2412 men killed, 186,567 tons were mined for each life lost.

The report by John Birkinbine, on the movement of Lake Superior iron ores in 1909, has also been issued by the Geological Survey. The most striking feature is a map which shows the routes of shipment of the ores and the points to which they were shipped. The total shipment of iron ores from the Lake Superior region in 1909 amounted to 42,504,110 long tons, a quantity greater than that shipped in any preceding year. Most of this ore was shipped by water, during the seven or eight months of the year when navigation is possible on the Lakes. The principal shipping docks are at Two Harbors and Duluth, Minn., Superior and Ashland, Wis., and Marquette, Mich. Nearly 36,000,000 tons shipped from the docks passed through the Sault Ste. Marie canals and through Lakes Michigan and Huron to their places of destination, the greater part of the ore being delivered at the receiving docks at Toledo, Sandusky, Huron, Lorain, Cleveland, Fairport, Ashtabula, and Conneaut, Ohio; Erie, Pa.; also Buffalo and Tonawanda, N. Y. Most of the ore received at these ports is consumed in eastern Ohio and western Pennsylvania. In 1909 about 23,000,000 tons were sent to the Cleveland and Pittsburg region.

The Lake Superior ores represent about 80% of the total iron-ore production of the United States. The total production of iron ore in the Lake Superior region, by ranges, to the close of 1909 is shown in the following table:

	Tons.
Mesabi	195,703,424
Marquette	91,903,991
Menominee	71,313,115
Gogebic	60,820,503
Vermilion	29,125,385
	448,866,418

These figures do not include stocks of ore which have accumulated at the mines.

SALT LAKE, UTAH

Utah Consolidated. — Silver Shield Mill. — Government Rescue Station.—San Juan Oil.

The time when the intermountain region will again see real competition in the smelting industry seems to be at hand. The first of the reverberatory furnaces at the new International smelter has been lined, a second is almost ready for the lining, and a third should be ready for operation soon after the first of the month. The Utah Consolidated's contract with the Garfield plant is about completed, and as soon as the last of the contracted tonnage is delivered the ore will be turned over to the International. The statement that shipment to the new plant will be at the rate of 1000 tons per day is something of an overestimate as the company does not contemplate, for the present, at least, shipping any more to Tooele than it is shipping at present to Garfield, namely 800 tons. With Utah Consolidated operating under its new contract and sharing in the profits of the International, it should be able to return to the dividend-paying class although it would be rather optimistic to look for it to go at once on its old basis of $2 per share.

The Silver Shield, of Bingham, has completed the foundations of its new concentrating mill and the work of erecting the building and installing the machinery will be pushed as rapidly as possible. The plant will operate at 60 tons per day at first, with the expectation of increasing the capacity as the mine is able to supply it. Free & Taylor, the contractors on the new Snake Creek tunnel, have placed an order for 14,000 ft. of 16-in. galvanized steel ventilating pipe for use in the tunnel. Delivery is to be at the rate of 400 ft. per month until the contract is completed. The tunnel is in nearly 800 ft. and is progressing at the rate of about 400 ft. per month. With the arrival of the electric haulage locomotive, which is expected about the first of August, the equipment will be complete. The tunnel will begin cross-cutting some of the vein systems of the district at about 3000 ft. and from that time on should make some interesting disclosures. The hoisting plant of the Mammoth, which was badly wrecked in an overwinding accident, has been examined by an Eastern engineer and the damage found to be less than was first supposed, although it will be necessary to build a new head-frame and drum for the hoist. A small hoist is being installed at the adit-level that will permit of operations to 1000 ft. while repairs are being made which will be for about two months. The first work will be the repairing of the shaft timbers which were torn out by the broken cable and the cage dropping. Two thousand feet of cable will have to be replaced. The Primrose group, which has lain idle for a long time, has been leased and operations will be resumed in a short time. In the early days this group of claims produced about $100,000 at a shallow depth, but operations were discontinued when copper was found.

Utah will have one of the new government rescue stations which will be established at or near Salt Lake City. This station will be expected to serve the coalfields of Utah, western Colorado, and southern Wyoming. The Indian Queen, in the Beaver district, has been closed down indefinitely. The company has money in the treasury and has done a large amount of development, including a 5000-ft. adit which has attained a depth of 1200 ft., but the ore has never been found.

Engineers for the Santa Fe and the Denver & Rio Grande are in the San Juan oilfields making reports for their respective companies. The Chicago Oil Co., which is supposed to be backed by the Standard Oil interests, has three rigs on the way and is to begin operations in this field. There are five wells now in the field, which are producing oil in commercial quantities. The San Juan fields are unquestionably large and have prospects of producing a great amount of oil, but there has been a considerable amount of misstatement and exaggeration about them of late. One curious feature of a portion of this country is a natural spring of peculiar oily fluid which will not burn but which has been found to make an excellent compound for cleaning out scaly boilers. It has been tried with success by the Salt Lake railroads and a carload has just been shipped to the Seaboard Air line. It is used in its crude state without any refining. The Cardiff in Big Cottonwood, has commenced shipping, the first carload netting $50 per ton. The company has been developing and unwatering for about a year but now is in shape to maintain a small regular production. A reminder of old days come from a trial in Ogden in which certain stockholders of the Golden Rule mine are seeking to recover the sums which they paid for their stock, charging that the samples, on the strength of which they invested, were salted. Assays of $952 per ton in the 'promotion samples' dwindled to 5c. when the mine was sampled by a disinterested person.

BLACK HILLS, SOUTH DAKOTA

Labor Conditions.—Tin Mining.—Wasp Rebuilding Mill.

Since the resumption of work by the mines of the Black Hills, using non-union labor, conditions have gradually improved. A large part of the new labor supply was drawn from Michigan, Wisconsin, Missouri, and Kansas, with some from Colorado, Montana, and other Western States. It was necessary to break in the new men to conform with Black Hills methods, but this was an easy task, even with the men from lead and zinc-mining districts. How well the men have taken to local methods is instanced at one property, where in treating a little over one hundred tons per day, the work of mining and milling is accomplished by a force consisting of five less than was used prior to the lockout. At this property the average tonnage has run a little higher, and since resuming not a minute's time has been lost in the mill. This is not an exceptional case, but is an example of conditions at all of the properties. The

organization of the Homestake Employees' Benefit Association has been nearly completed. This organization practically covers the field of a labor union, in so far as sick and death benefits, recreation rooms, and grievance committee is concerned, and its membership will undoubtedly include nearly all of the employees of the Homestake. The company will assist the organization in every way, taking care of all of the clerical work at the general offices in Lead, and in addition making a cash contribution each month, amounting to not less than $1200. Under the plan as proposed each member will pay one dollar per month, entitling him to all rights in the association, as well as medical, surgical, and hospital care.

At Tinton, in western Lawrence county, the Tinton company is milling in an experimental way, and the prospect seems good for developing a big tin mine. The mill was built several years ago, was found to be inadequate and improperly equipped for the class of ore mined, and has been remodeled and repaired all out of semblance of its former appearance. It is now an up-to-date plant, and when enlarged on present lines will make good production. The mine shows a big vein of characteristic greisen, with a good tin content. E. C. Johnson is still working on the Gertie tin mine, at Hill City, having lately had constructed a grinder of his own design, at the Homestake shops, for crushing ores. This machine resembles a tube-mill, but uses iron rollers in place of pebbles. Exhaustive tests were made by Mr. Johnson with a small machine, before the construction of the full-sized one. He expects to start milling within thirty days. The Pa-Ha-Sa company, owning the old Harney Peak Tin company holdings, has nearly completed the dewatering of the Cowboy shaft. In this shaft the Harney Peak had one of its best tin showings, and A. R. LeDoux, general manager, is anticipating good results with further developments.

The gypsum and stucco industry is growing to considerable proportions in the foothills of the Black Hills. Two big plants are operating and four more are either under construction or getting money together for active work. The plants are situated at Blackhawk, Rapid City, and Hot Springs. Securing a high-grade gypsum from immense beds which require but a few feet of stripping, these plants turn out an excellent grade of plaster at a small cost. A splendid market is found east and north of the Black Hills where newcomers are rapidly settling on homestead lands.

The Black Hills Development & Financial Corporation, operating at Carbonate, has just shipped two cars of ore to Denver. This is the first production from this camp in nearly a quarter of a century. The camp was first opened and known as a silver camp, producing over a million dollars in a couple of years. The ores just shipped showed a preponderance of gold value. The company is engaged in pumping out some old workings, preparatory to following up the old high-grade shoots in a search for milling ore. Much to the gratification of the management, expenses are practically being paid by sorting over old dumps. R. Bunce, of Deadwood, is manager. Paul Danckwardt has a force of men at work repairing the Gilt Edge-Maid mill, at Galena, preparatory to a resumption. Since suspension a year ago the property has changed hands, a Chicago corporation, headed by J. S. Ford, having secured it. Several changes are being made in the mill, one of the most important being in the crusher. It is expected that operations will be resumed about September 1. Work is progressing favorably in rebuilding the mill of the Wasp No. 2, which was destroyed by fire in January. The foundations are completed, part of the machinery delivered, and lumber is now coming rapidly. The plant will have a capacity of 300 tons, with some minor improvements over the old mill. It is being erected at the head of a dry gulch, instead of on the old site overlooking Whitewood creek. The tailing dump was getting a little too close to the C., B. & Q. tracks, and the disposition of the mill refuse would have been a serious problem in another year or so. The new site also makes available a quantity of ore which will be moved down grade to the mill. The difference between dropping ore down grade or hauling it up is a big item

NEW YORK

Copper Curtailment.—Smelting Situation.—Bouse to Planet Railroad. — International Smelting & Refining Co. — Silver. — Standard Oil.

It is a continual matter of surprise that the weakness of the copper situation should affect the entire market so strongly as it does. Nothing could more clearly demonstrate the interdependence of our highly developed commercial structure. Like a chain the market can be no stronger than the weakest link. The week has seen a marked turn in the sentiment as to the future of copper. It is said, and evidently credited in high financial circles, that an agreement looking toward the restriction of the world's copper output has been entered into by some of the principal factors in production. There have been rumors of conferences abroad for some days, but the statement, which is couched in positive terms, is to the effect that the Rothschilds, controlling the Rio Tinto; John D. Ryan, representing the Amalgamated Copper Co.; and Daniel Guggenheim, speaking for the porphyries, have reached an understanding as to curtailment, the details of which are not, and probably will not be, made public. It is expected that the producers on this side will readily fall into line with any reasonable program which promises effective improvement. It is admitted on all sides that nothing more than a tacit 'gentleman's agreement' is possible. Any iron-clad coalition of the principal producers would undoubtedly be pounced upon by the authorities in Washington, no matter how temporary such an agreement might be. Notwithstanding this very illusory promise of relief, the substance of which must perforce remain intangible and unrecorded, its effect was immediate and pronounced both in the market for the metal and in the price levels of the leading copper issues. Copper in London was marked up £1 per ton, New York ⅛ and ¼c. per pound. Amalgamated Copper declared its regular quarterly dividend of 50c.; although the shares moved up with the rest of the copper list on the promise of better metal market conditions, Amalgamated is bound to continue as a weak spot in copper on its income basis, especially as there is no surplus accumulating large enough to give promise of future melon cuttings. Boston & Montana declared a quarterly dividend of $4; $2 regular and $2 extra; this is an increase of $1 over the distribution of three months ago and is announced by the company to be declared out of the dividends received from the company's holdings of Anaconda. An interview, given out this week, by W. A. Clark, former Senator from Montana, is being widely quoted as evidence of an understanding on the part of the larger producers, that all of the more important interests, at least, are to help maintain prices. Mr. Clark also takes occasion to criticise the porphyry coppers on the usual ground that they have boosted the price of their shares, while mining the rich ore, without making proper charges for later increased costs or for plant depreciation. None of which is new, but it is timely, and as Mr. Clark is probably the largest private individual factor in the copper world, he has a more than ordinary right to be heard. His position is unique, in that he has chosen to act as an individual, rather than as the head of large corporate organizations. His corporations have always been mere matters of convenience in the conduct of his business. There is no other individual in the copper world who occupies a similar position. While it is undoubtedly true that such concerns as Phelps, Dodge & Co. and the Calumet & Hecla, will diplomatically deny any understanding with any other concern, it is equally beyond doubt that Mr. Ryan and Mr. Guggenheim knew for whom they could speak before they went into conference with the owners of the Rio Tinto.

One more important, if not the most important, phase of the understanding said to have been reached, and one which is of interest to all producers, is the question of supremacy in the smelting industry. It has been evident for some months that the smeltermen had settled into a grim fight. If they have decided to agree, the mining industry in

general will be eager to learn the conditions of the truce or the treaty, as the case may be. Ray Consolidated and Chino are in course of hurried preparation for outputting copper. If the ores from these properties are not to be used to hold down the competition in the smelting industry a little less haste may be expected in their development. Sherwood Aldrich, president of the Ray Consolidated, is just home from a month in France and Germany. He says that progress at the Ray Consolidated is satisfactory, that the structural steel for the mill is largely up, that the grading for the power plant and for the smelter is completed, and the steel deliveries for both will begin soon. The churn-drill on the Planet property near Parker, Arizona, has cut some rich ore. This property was purchased by the Lewisohns last fall, and since the option was taken over the exploration work has been in progress. It is expected now that a spur will be run by the Arizona & California railroad from Bouse to Planet, and the moment transportation is provided the work of erecting a new smelter will begin. Boston and Duluth interests have organized the Boston Miami Copper Co., taking over some forty claims adjoining the Live Oak just southwest of the Miami, the Inspiration, and the New Keystone in the Globe district of Arizona.

The Utah Consolidated is having a great deal of trouble with its new tramway, which carries the ore four miles from the mine to the ore-bins of the new smelter of the International Smelting & Refining Co. For a part of the distance the line runs up a steep mountain side and the tension when the line is carrying loaded buckets is tremendous. Although the net earnings of the International Smelting & Refining Co. are showing a material increase over last year's profits, it is not expected that there will be any increase in the quarterly dividend to to be declared next month. The company pays 8%. Eearnings for the first half of the current year were at the rate of 14%. A cut in the dividend on the National Lead common stock from 5 to 3% precipitated a drop of about 17 points and a decline of nearly 6 points in American Smelting & Refining. Such progress as 'Smelters' made therefore on improved outlook for copper was nullified by the drop in lead. It is somewhat exasperating for the followers of the Canadian market to note only small fractional advances in Cobalt stocks generally, and to see declines in a few of the principal issues in the face of an improved market for silver. Edward Brush, vice-president of the American Smelting & Refining Co., credits the recent rise in silver to heavy losses of some speculators in the metal, who were unexpectedly required to make deliveries on their commitments to the India Specie Bank. While on its face this might appear to be wholly a matter of market maneuvering, yet it indicates two things that are most satisfactory for silver; first, that the Specie Bank only cleaned up the spot silver market after carefully investigating crop conditions in India and finding them satisfactory; second, the management of the Specie Bank evidently expects, and possibly has certain knowledge, that the Indian Government, which has not been a buyer of silver for three years, will come into the market this fall. These conditions will give a firm tone to the silver market and will be of great importance in the silver camps of Mexico. Cobalt can produce silver at 10 to 13c. per ounce in some instances, and, assured of large profits in any event, the operators and speculators of the camp alike are evidently inclined to disregard conditions prevailing in the market for the white metal. The Hudson Bay Co. at Cobalt has decided to erect a concentrator on the property adjoining the Trethewey. A 20-stamp mill and concentrator with a capacity of about 80 tons per day will be built. Application has been made to the Government of Canada by Arthur Ferland, W. C. Chambers, Charles Richardson, and others, for a Dominion charter to construct a railway 42 miles in length through the new gold camp of Porcupine, connecting the Temiskaming & Northern Ontario railway with the Metagami river, which provides open water transportation to the Grand Trunk Pacific. Mr. Chambers is a prominent railway contractor of Toronto and one of the controlling factors in the Chambers-Ferland mine at Cobalt. Mr. Richardson is a director of the Temiskaming mine. Work on the new road will start as soon as favorable action is taken upon the application. Mining progress at Porcupine is reported to be steady and healthy. A 30-stamp mill has been ordered for the Timmins property and other mines of the camp are said to be contemplating the installation of like plants. A trial run of a small lot of unsorted ore on the Timmins, which was put through the little 2-stamp mill, is said to have shown a value between $200 and $300 per ton.

There is more interest in the Western precious-metal stocks just now than for some time past. Three of the Nevada camps have been getting into the limelight: Fairview, by reason of the entrance of the Goldfield Consolidated interests into the new Nevada Hills Consolidated Co., and the announcement that sufficient ore had been developed in the mine to warrant the erection of a 100-ton mill as a first unit of a large milling plant; Tonopah, by reason of the tremendous showing of the Belmont, which is earning more than $150,000 net per month and which promises to increase by $100,000 additional each month, July earnings are expected to be at least a quarter of a million, possibly more; and Goldfield, by reason of unexpected activity in Florence. Charles S. Herzig is now in Goldfield for the purpose of examining the Florence under an option, said to have been given to a New York brokerage house, presumably for the purpose of making a market for and distributing the stock of the company.

The discovery of gold at the Batopilas property is considered important. The largest vein is said to show some four feet in width and to assay $20 to $40 per ton. Batopilas is to have a complete new equipment and the general manager of the company is now making contracts with the machinery houses for the new plant.

The organization of the Batopilas Mining, Smelting & Refining Co., Ltd. of London, to take over the lease of certain groups of mines of the Batopilos Mining Co. of Mexico, has been successfully completed. Fifty thousand shares of the English company have been underwritten and listed on the Paris Bourse, 75% of the total stock being owned by the Batopilas Mining Co. It is proposed to make similar arrangements for working other mines of the Batopilas company and also starting new mines at favorable points throughout the company's concession from the Mexican Government, which covers an area of 61 sq. mi. It is believed that the more extensive operations should assure an increased revenue to the company from its properties, some of which have yielded silver since their discovery by the Spaniards in 1633. The first unit of the Palmilla Mining Co.'s new mill at Parral, is nearing completion. The power house is nearly finished and the steel work for the mill will be completed the early part of August. It now appears as if the plant would be in operation by October.

Samuel Untermeyer has a $20,000,000 oil company for London capital. The properties are in the vicinity of Bartlesville, Oklahoma, and the building of a pipe-line to tidewater on the Gulf is contemplated. There are some big competitors springing up around the Standard Oil Co. John W. Gates' new concern, the Texas company; the Mexican Eagle, backed by the Pearsons of London and now engaged in a life and death struggle with the Waters-Pierce branch of the Standard Oil Co. for the oil trade of Mexico; the Associated Oil Co. of California, recently listed on the New York Stock Exchange; and Mr. Untermeyer's recent creation are among the principal ones, and these seem apt to grow to a point where they cannot be stifled, as was formerly the usual fate of would-be rivals of the Standard. What with competitors reaching after trade and an extended line of battle engaged in repelling the attacks of the law departments of a large number of the States of the Union, as well as that of the Federal Government, seeking to annul the company's charter, the Standard Oil Co. may be forgiven some nervousness. A gain of $13 per share in the stock on the curb one day and the loss of $6 per share the next seems to point to a situation that is beginning to get on somebody's nerves.

General Mining News

ALASKA

(Special Correspondence).—The Ellamar Mining Co., whose mine is at Ellamar, Prince William sound, has completed a coffer dam by which 250 ft. of its vein outcrop, formerly under water, has been exposed. The dam forms a horseshoe curve and is about 400 ft. in length. It was constructed of 4 by 12-in. timbers, driven to make two parallel walls, leaving a 15-ft. space between them that was filled with glacial clay. This made an effective seawall 20 ft. higher than the surface of the water at low tide. Drain pipes serve to carry the water from the enclosed area, and to supplement this arrangement a steam pumping plant has been installed. The exposed outside timbers, encasing the wall, are creosoted. The shaft, now at a depth of 600 ft., was sunk some distance from the waterfront on higher ground. The vein is in a slate formation and is 80 to 300 ft. wide. The workings, which are extensive on a number of levels, lead out under the sea. It is proposed to carry the stopes to the surface in that part of the vein the cropping of which has been relieved of water by the coffer dam. The ore is said to assay 32% iron and 10 to 13.5% copper. In fact, the last shipment, which was in March, assayed 13% copper, and $2 gold. It is believed the general average of ore that is to be shipped this summer and fall will be 10% copper. F. M. Jordan, general manager for the company, states that shipping is to begin in August to the Tacoma smelter. L. L. Middlekamp is in direct charge of the operations.——The Alaska Northern Railroad Co. has 71 miles of road in operation from Seward to Kern creek, and the work of extending the line from the present terminus to the Matanuska coalfields, near the Susitna river, a distance of 170 miles, is in progress. There has been some travel from its Kern creek station to Iditarod, 400 miles distant, this season.

Ellamar, July 22.

ARIZONA

COCHISE COUNTY

At a recent meeting of the board of directors of the Gold Queen Mining Co., at Courtland, B. S. Taylor was elected president, and D. S. Drew vice-president. The board decided to erect a 15-stamp mill and contracts for the machinery will be let at an early date.——The shaft of the Bismark Gold Mining & Milling Co. at Cochise, is down 62 ft. on a lead-silver-gold ore that is valued between $4.50 and $23.50 per ton.——The adit at the Virtue property in the Paradise district is in 744 ft. and it is estimated that it will take about 350 ft. additional to crosscut the ore.——In the Dragoon district, the Higgins claims are being surveyed for patent.——The connection between the winze sunk on the 1400-ft. level of the Lowell and the 1600-ft. level of the Sacramento shaft of the Copper Queen is expected to break through in a few days. The 7-ton motor that was installed recently on the 400-ft. level of the Holbrook, is running steadily and giving complete satisfaction.

MOHAVE COUNTY

Prisk & Perdue who have a lease on the Home Pastime mine in the Mineral Park district, shipped a car of ore recently to the Needles smelter that assayed $50 to $200 per ton. This makes the sixth car that present lessees have shipped.——The raises from the adit level of the C. O. D. mine have been completed and the ore is now ready for stoping, while the grading for the new 100-ton mill is well under way.——Four feet of zinc ore has been opened on the back vein at the 100-ft. level of the Golconda mine, by the cross-cut into the foot-wall. There are four levels now opened for stoping and it is expected that the production rate in the future will be 1000 tons per month.——The Ruth-Rattan Mining & Milling Co. has been formed to take over the Ruth and Rattan claims of the Rattan Mining Co., in the San Francisco district west of Silver creek. There is a 200-ft. shaft on the Ruth which ..ed a 3-ft. vein of $20 ore. The company will move the old 10-stamp mill from its present site on the Colorado river to the mine, and will install a complete cyanide plant. Eli Hilty will be superintendent.

YAVAPAI COUNTY

The cross-cut from the foot-wall drift on the 800-ft. level of the Little Daisy mine at Jerome, has opened over 30 ft. of copper ore.——C. N. Smith, of Milwaukee, has purchased the Bulger group on Cherry creek and will commence work about September 1.——New machinery has been shipped to the Arkansas & Arizona Mining Co., and the orebody cut by drill-hole No. 2 will be opened.

YUMA COUNTY

C. H. Scheu, of Los Angeles, has secured an option on the Desert Butte silver-lead mine near the station of Kilbeck, on the Parker cut-off, and will commence development September 1.

CALIFORNIA

BUTTE COUNTY

Through the efforts of the Anti-Debris Association, the gold dredges which have been operating on Honcut creek, have been enjoined by K. S. Mahon, Judge of the Superior Court of Sutter county. The injunction stated that the dredges of the defendants dumped the debris into Honcut creek, and that it in turn found its way into the Feather river, damaging the channel in Sutter county and greatly endangering the adjoining property from floods.

NEVADA COUNTY

The Lilly Consolidated Gold Mining Co. has been incorporated to prospect the vein found on the Mitchell ranch between Nevada City and Grass Valley.

SHASTA COUNTY

Two of the furnaces at the Mammoth smelter have been closed down temporarily as the temperature of the smoke passing through the bags at the present rate is too high. As a result 100 men have been dropped from the payroll and the Quartzville mine at Old Diggings closed down. This property furnished the flux for the Mammoth ore and is held under lease by the company which has an agreement to mine 15,000 tons annually from the property. As this amount has been taken out this year the suspension will not affect the lease. David P. Doak, who owns 5080 acres of timber land extending from Kennett to Winthrop, has filed suit against the Mammoth company for $76,000, alleging that the smelter smoke has damaged the timber to that extent.

SIERRA COUNTY

(Special Correspondence).—Sierra City is at this time having quite a revival in a mining way. The old Columbo Mining Co. is under bond to C. W. Thompson and associates, of Oakland, California. The old No. 1 adit is being cleaned out and a thorough sampling will determine whether the mine will be opened on an extensive scale. Several good-sized stringers of high-grade ore have already been found.——The old Chippes now operated by the Swastika Mining Co., is erecting a 10-stamp mill and the work in the mine has been temporarily discontinued until the plant is completed. L. H. Holley is superintendent.——The Phoenix has been re-incorporated by all the claimants to the property. The operators installed an 8-drill air-compressor to operate four machine drills. Also the mill is being repaired and a new Pelton wheel is installed to drive the compressor. The old adit on the property is being retimbered, and mill and mine should be working at full capacity by September 1. This mine has been closed for nearly 15 years.——J. E. Coghlan, who has a lease on the Keystone property, has just completed his second mill-run and is getting ore from the old workings for the next.——The Cleveland Gold Mining Co. is starting a mill-run from the lower adit where it has a vein of low-grade ore 30 ft. wide.——The Sovereign mine in Ladies canyon, is driving a 1600-ft. adit to tap the vein exposed in the upper workings.——The county supervisors at their last meeting ordered the road to be surveyed from Sierra City to Gold

lake, to connect there with the Plumas county road from Clio, on the Western Pacific. The road will go by Salmon lake, Sardine lake, and near the string of 40 lakes on the ridge, and will be 20 miles long, greatly facilitating freight and passenger service.

Sierra City, July 25.

SISKIYOU COUNTY

P. W. Fisher, who is developing a group of claims on the north fork of Humbug creek, opened a seam of ore that assayed over $1000 per ton.——The owners of the Gray Eagle claims on Indian creek, are doing the assessment work for the year.

TRINITY COUNTY

(Special Correspondence).—The Enterprise Mining Co., in the East Fork district near Helena, is confining its work to development only. The property consists of several claims and a water-right, and is equipped with a 10-stamp mill, saw mill, and electric light plant. The mine is owned by Boston capitalists, and is under the management of George Fenwick. Considerable ore has been blocked out

Map of Portion of Trinity, Shasta, and Humboldt Counties, California.
(After MacDonald, U. S. Geol. Survey.)

and the mine is in condition to commence stoping at any time.——The East Fork Developing & Mining Co. has an excellent prospect and is developing it by an adit and incline shaft on the vein. W. S. G. Todd is manager.——On the same branch of the east fork is the Golden Chest group, owned by T. J. Rochford and associates. There is more development on this property than on any other in that district and a good grade of free-milling ore with considerable telluride, has been opened. The Bonanza group of J. L. Johnson and the Trinity group of William McClaren are in the same district. All of these properties contain small high-grade stringers, it being an easy matter to pick up specimens showing free gold on any of the dumps.

Carville, July 25.

TUOLUMNE COUNTY

(Special Corerspondence).—The Tuolumne Consolidated of California will shortly receive a dredge and other machinery for its gravel property near Phoenix lake, and it is probable that in the near future another dredge will be purchased. The company is employing about 80 men, and is rushing work on its dam, ditches, and buildings. Development is also in progress, the prospects showing that the gravel is rich and uniform in value.——A compressor, larger than the one now in use, is to be installed at the Mangante mine, and the working force considerably increased.——The mill at the property of the Springfield Tunnel & Development Co., is in operation and results are said to be satisfactory.——The Black Oak mine is being unwatered to the bottom level, preparatory to sinking.——The Jubilee mine, formerly known as the Hazel Dell, is being actively worked, and more machinery is to be installed in the near future.——The Elizabeth mine, situated near the Hazel Dell, has been bonded to Bernard & Anderson, and work will be commenced at once.——The drift being driven from the bottom of the shaft at the Gold Ship Mining Co.'s property, near Groveland, has reached gold-bearing gravel and it is expected that bedrock will be exposed before long. It is the intention of William Graham, the manager, to install a mill to crush the gravel, and arrangements are being made for electric power.

Tuolumne, July 25.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—The Capital Mining & Tunnel Co. has started to drive an adit on the West Aetna vein. It is proposed to drive 700 ft. to intersect the main raise on the Aetna vein to obtain a circulation of air.——A sale is pending for the transfer of the Strumberg group of claims on Covode mountain. The consideration is given at $50,000.——D. H. Burlingame has secured a lease upon the Santiago mine and mill. On an average of 30 tons per day of smelting ore is being shipped.——Shipments of ore have been started from the Oneida mine on Trail creek. The return on the first carload was 1.95 oz. gold and 1.03 oz. silver per ton. John Owen is manager.——A shipment of a carload of ore from the Princess Alice mine that was made last week brought a settlement of 1.28 oz. gold and 3 oz. silver per ton. J. F. Kaminky is manager.

Idaho Springs, July 23.

GARFIELD COUNTY

At the Grey Eagle claim at Goldstone, 11 miles north of New Castle, the vein is 2 or 3 ft. wide, and averages $35 in gold, with a few ounces silver per ton. The vein is in a fissure in granite, the ore being a sulphide of iron. The vein has been opened on several levels and it is the intention of the company to erect a mill in the near future. F. J. Bodfish is manager.

GILPIN COUNTY

(Special Correspondence).—The Sternberger power plant on Fall river has been completed and electric power was turned on last week. Electricity is to be sold in the Fall River, Russell, and York districts. The plant cost $200,000.—The new shaft house on the British mine has been completed, and machine drills have been brought into use.——The mill building for the Golden Sun Mining & Milling Co. has been completed and the machinery is now being placed in position. The plant is to have a capacity of 40 tons per day.——Jones & Oliver, leasing on the Mitchell mine, have sold a one-third interest to Thomas & Keppler. The new pool will at once erect a shaft-house and install machinery.——Work has been resumed on the East Flack mine by Christopher & Co. The shaft, down 150 ft., will be sunk another 100 ft. If the showing warrants machinery will be purchased.——New macninery has been sold by Stroehle & Son to the operators of the General Jackson property situated in Elkhorn gulch.

Central City, July 22.

LAKE COUNTY

Good progress is being made in driving the Birdella adit by the Gleason Gulch Mining Co., the breast now being in nearly 700 ft.——The Famous shaft in Big Evans gulch will be down 700 ft. in a few days. A station will be cut, pumps installed, and lateral work started to develop the ore-shoot.——The shaft which is being sunk on the Free America and Little Galesburg claims on the north side of Breece hill, has cut a heavy flow of water and pumps will be installed before sinking can be continued.——The lessees on the Montgomery are shipping about 75 tons of ore per day and prospecting the orebody that was opened in the Yankee Doodle ground. The drifts from the Lime shaft have been cleaned out and a wagon-road completed to the mine. When the work starts underground the lessees expect to ship 25 tons of ore per day.——Beamer & Co., who

have a lease on the Adelaide, are still working in the upper levels of the mine but are preparing to clean out the old shaft and commence exploration of the orebodies in the lower portion of the ground which has been drained by the Yak tunnel.——The old Mab dump is being screened by lessees and material shipped that assays 40 to 50% lead.——The upper levels of the Greenback are being prospected and if found to contain ore of commercial value the lower portion of the mine will be unwatered.

SAN JUAN COUNTY

The cross-cut on the third level of the Lutz-Abbott-Bonner group in the Silverton district, has opened the vein exposing a 16-in. stringer of sulphide ore. There are 15 men working in the mine from which a carload of ore was shipped to the Kuenzel smelter a short time ago. A. S. Sturgeon is manager.

TELLER COUNTY

A washer and gasoline engine has been moved to the dump of the Mary McKinney property, and the rock will be treated by lessees.——On the Dillon property the Carol Mining Co. is cross-cutting toward the Granite shaft to open an orebody that had been found before the closing of the main shaft.——The water in the Eclipse shaft has been lowered 375 ft. and it is expected that the mine will be completely cleared to the lowest level, 500 ft., in a few days.——The Jerry Johnson shipped a $4167 gold bar to the mint last week as the result of the clean-up of the Gaylord mill.——Work has been resumed at the Lower Dead Pine by the sub-lessees Keagle & Company.

NEVADA

ESMERALDA COUNTY

Charles S Herzig, representing Eastern capitalists, has purchased the control of the Jumbo Extension Mining Co. which owns considerable property at Goldfield and Diamondfield. The Goldfield group consists of the Gold Wedge, Polverde, Vinegorone, and Dick Bland fractional claims, and the Diamondfield group includes the Gold Coin, Saddle Rock, Three Friends, Three Friends Fraction, Black Butte

Florence Mine and Mill.

No. 1, and Black Butte Fraction. The property has been worked almost exclusively by lessees, the company having derived a revenue of approximately $50,000 in royalties. It is understood that Mr. Herzig is also negotiating with Parker and Lockhart for the control of the Florence.——About four miles west of Goldfield and a little south of the Ben Hur group James Carson has found a 7-ft. vein which contains several inches of high-grade ore.——The Goldfield Consolidated Mines Co. has ordered a 24-in. water-jacketed furnace, a cupeling furnace, and blower from the Allis-Chalmers Co. with which to refine the bullion and precipitate at the company's mill.——The settlement from the Hazen sampler for the ore shipped recently from the Grutt-Balloon Hill lease amounted to $111 per ton. The ore was stoped on the 350-ft. level.

LINCOLN COUNTY

The force at the Mendha mine in the Pioche district, has been increased to 30 men, and the teams are hauling 20 tons of ore per day to the railroad——The Pioche Metals Mining Co. shipped a carload of silver-lead ore to Salt Lake a short time ago that was obtained while sinking the shaft to the 300-ft. level. Drifts have been started in both directions along the contact at that point.——The management of the Consolidated Pioche Mining Co. has decided to sink the No. 1 shaft to the 1200-ft. level by contract, and is receiving bids for the work.——The Highland Mary which is under the direction of S. H. Babbitt, shipped two carloads of silver-lead ore to the Salt Lake smelter recently.——It is reported that the Pioche King which is situated between the Pioche Golden Prince and the Prince Consolidated is to resume shortly.

LYON COUNTY

The Keystone mine in the Mount Grant district, which was sold last April to a Boston company, has been closed down as the result of the development by the company has not held up to the original report on the ground. The company built a modern assay office and commenced the erection of a 40-stamp mill, part of the supplies for the plant being now on the road.——The Black Rock group, six miles east of Yerington, has been sold to Racine capitalists, and will be operated by the Black Diamond Copper Mining Co. There are four veins on the group which can be traced a distance of 2600 ft. on the surface. Two shafts have been sunk on the ore to a depth of 80 and 150 ft. respectively, opening a copper ore with some gold and silver.——L. H. Bartholomew, who is operating a 2-stamp mill on his property in the Mount Grant district, shipped a small gold bar from the recent clean-up. The ore was taken from a winze which is down 30 ft., and if the shoot continues of similar value Mr. Bartholomew will add more stamps and a cyanide plant.

NYE COUNTY

(Special Correspondence).—The Belmont shaft at Tonopah is being widened to the surface and a new plant will soon be installed.——An important body of ore, 20 to 30 ft. wide, has been struck at the 800-ft. point in the MacNamara. The vein appears to be an entirely new orebody and extends the proved area of the Tonopah district considerably to the west. Sufficient development has not progressed to demonstrate the size or value of the vein, but good milling ore was opened. A raise is being driven to prospect it farther. Arrangements have been made to change the steam hoist into a 100-hp. electric hoist, in order to handle the ore opened on the new level.——The Mizpah Extension shaft has passed the 860-ft. point and is progressing at the rate of two feet per day. It will be sunk to the 1000-ft. level.——Operations on the 1035-ft. level of Tonopah Midway have been stopped owing to the presence of large quantities of gas. Powerful ventilating apparatus will be installed as soon as possible.——It is rumored that the West End company is considering the installation of a mill. A Crane ore-washer and picker is now in operation.——The Montgomery-Shoshone mill is treating about 5200 tons of ore per month and diamond drilling is under way from the winze on the 700-ft. level.

Tonopah, July 22.

STOREY COUNTY

The ore taken from the stopes on the 2000-ft. level in the southwestern portion of the Ohpir mine at Virginia City, has improved considerably the last few weeks, an average of over $64 per ton being obtained for 40 cars. On the 2300-ft. level in the south drift from No. 1 west crosscut the ore assays $9 per ton in the face.——The pumps in the C. & C. shaft are doing good work, the water now being 250 ft. below the 2350-ft. level. Excellent progress is being made in removing the debris below the 2500-ft. level and the shaft timbers are found to be in good condition.——Consolidated Virginia is stoping over 200 tons per week which is being shipped to the Sutro mill.——Work was suspended for a few days last week at the Overman and Seg Belcher mines owing to trouble with the electric cable in the shaft.——Joseph Dietrich, who is operating a lease on the croppings of the Choliar property, paid the company $1791 royalty for ore extracted during the month of June.

WHITE PINE COUNTY

A crew of graders and carpenters are at work at the Amalgamated Mining Co.'s property near Blackhorse where the company is erecting a mill to treat the ore from the San Pedro mine, and a number of other properties in that district. James H. Marriott is manager for the company. ——Work has been temporarily suspended at the Boston Ely as the shaft, which is 1227 ft. deep, has failed to open a body of commercial ore though it has passed through several hundred feet of leached material. The property is to be examined by an engineer and a new method of development outlined.——The Cone brothers, who have a contract to drive a 300-ft. adit on the Ely Silver Lead Co.'s ground, are making good progress, having completed 150 ft. of the work.——Another carload shipment of ore valued between $40 and $45 per ton was forwarded last week from the Ely Consolidated to the Salt Lake smelter. There was about 50 tons in the lot which was taken from the No. 2 drift from the Brilliant shaft, the vein averaging two and one-half feet in width.——Work at the Giroux has been considerably increased and it is reported that the ore will later be shipped to the International Smelting & Refining plant at Tooele.

UTAH

BEAVER COUNTY

The Utah United Copper Co. has opened 18 in. of rich copper ore on the 200-ft. level of its property in the Beaver Lake district, 12 miles west of Milford. The company is to sink the shaft to the 400-ft. level and cross-cut as it is expected that the sulphide zone will be found at that depth. ——A body of copper ore has been found in the Red Warrior in the Star district. This comes as somewhat of a surprise to the operators as the company has been stoping silver-lead carbonate ore previous to this.——At the Rob Roy property the control of which is held by P. T. Farnsworth of Salt Lake, a modern assay office is to be erected and later a small mill will be installed. The company has secured a water-right that will supply power for the plant and water for the batteries.——The shaft at the Oak Leaf mine, ten miles west of Beaver, is down 500 ft. on a vein of carbonate of lead and silver which varies between four and eight feet in width.

JUAB COUNTY

The timbers in the shaft of the Mammoth property in the Tintic district, which were torn out when the engine ran away some time ago, are being replaced rapidly and the work will be completed the early part of August.—— At the Tintic Combination little work is being done except that necessary to keep the mine dry. An assessment has been levied on the stock and operations will be resumed as soon as sufficient money has been paid into the treasury.——The Bullock property at Silver City which has been closed the past two weeks on account of an accident to the engine has been started again. Work will be continued for the present in the north drift on the 210-ft. level but later an assessment will be levied for the purpose of raising money to purchase new machinery and continue sinking. Elmer Duncan is superintendent.——The Primrose group which is one of the oldest in the Tintic district, will probably be under active development in the near future as Salt Lake interests are to acquire a long lease on the property. The mine produced approximately $100,000 worth of lead-silver-gold ore in early day but was closed when the copper sulphide was reached.

SALT LAKE COUNTY

After a long period spent in development the Yosemite mines Co. of Bingham has unwatered the lower levels of the property and is in a position to commence active mining. The drift from the Mascotte tunnel was driven 1500 ft. to a point directly under the Yosemite No. 1 shaft which was tapped to drain the mine. When the company abandoned the 800-ft. level on account of the heavy inflow of water there was exposed a body of copper-iron sulphide ore on which the company now proposes to commence stoping. Previously the operators were only mining the lead ore and the old stopes are too badly caved at present to determine the amount available.——The Bingham-Butte Mining Co. which has been driving the Tiewaukee adit has been reorganized and will continue work as the Montana-Bingham Consolidated Mining Co. The new company will be incorporated for 1,500,000 shares which will be exchanged for the old stock and sold to raise capital for further development. The adit will be 2700 ft. long when completed. ——The old Passed Treasure group in the Big Cottonwood canyon is being prospected, and the old shaft which is down about 75 ft., cleaned out. The 15-ft. vein has been stripped so that 20 carloads of ore is exposed that assays in the neighborhood of $25 per ton. This will be broken for shipment at an early date.——W. L. Harwood has placed a force of men at work on the property of the Big Cottonwood Consolidated Mining Co., and a long cross-cut will be driven into the hill.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—The operations of the diamond-drill on the southern part of the Knob Hill property of the Granby Consolidated, have met with gratifying results. A continuation of the Knob Hill vein has been passed through for 100 ft. by the drill, and development is now being done toward the opening of this orebody. The Granby company has commenced diamond-drilling from its 400-ft. level which should prove the value of the ore from that to the 1000. Owing to the comparatively low price of copper the company is making no great effort to produce that metal to full capacity. At present six furnaces, of the eight, are operating at the smelter, treating something over 20,000 tons per week, of company ore, and 300 tons of custom ore.——The Hedley Gold Mining Co., shares of which were recently listed on the Boston Stock Exchange, is making regular shipments of rich concentrate to the Consolidated smelter at Trail. At the 40-stamp mill at Hedley a major part of the gold content of the ore is saved by amalgamation, the concentrate from the Frue vanners assaying about $80 per ton. The company has paid $107,520 in dividends since last August. This concern also owns the Copper Flat mine, Silver City, Mexico.——Work has been interrupted at the Rambler-Cariboo, the Lucky Jim zinc property, and other mines at Whitewater, Three Forks, and in the vicinity of Sandon and Kaslo, by devastating forest fires. At this writing, however, the fires are partly under control and other mines that have been threatened may escape damage. W. E. Zwicky, manager of the Rambler-Cariboo, is now in Spokane, arranging for the rebuilding of burned buildings and tramways, with a view to immediate resumption of work. The Consolidated Mining & Smelting Co. sustained $50,000 damage at the St. Eugene mine, Moyie, from fires. The flume was burnt away at places and large quantities of mine timber destroyed. The concentrator and upper tram are reported out of danger at this date.——In accordance with the amendment to the Coal Mines Region Act, passed in March last, three rescue stations are being established by the Provincial Government, one in the Crows Nest region and two on Vancouver island. Orders have been placed with the Draeger company, Pittsburg, for the necessary oxygen apparatus.——A new Portland Canal mining concern has been launched in London, named the British Columbia Gold Field Co. of Canada, Ltd. though the investing public is confused by the contradictory reports on the Portland Canal district. The director of the Geological Survey of Canada, W. R. Brock, says that while this is not yet a proved district he thinks it is the most promising opened in British Columbia since the boom of a decade ago in southeastern British Columbia. A large territory is available for prospecting both north and south of Stewart along the inland border of the Coast range granite.——The North Washington company has closed a 10-year lease for the Similkameen power plant near Oroville.——The Buffalo group of three claims near Poplar has been bonded to Vancouver interests and work will be started at once.——Work has been resumed at the Society Girl mine near Moyie after a shut-down of a few weeks. The property adjoins the St. Eugene.

Rossland, July 23.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. H. Weed is at Chicago.

C. W. Hayes is in Mexico.

R. B. Lamb was in San Francisco.

C. S. Herzio is at Rawhide, Nevada.

Henry J. Stehli is in San Francisco.

J. R. Philips has gone to Los Angeles.

D. W. Brunton, of Denver, is in New York.

Frank L. Booth is at San Francisco from Chihuahua.

R. A. F. Penrose, Jr., is at San Francisco for a few days.

E. W. Paaker, of the Geological Survey, was in New York.

S. B. Christy and E. A. Hersam are visiting Nevada mining districts.

W. Murdoch Wiley has been in San Francisco and Los Angeles this week.

Roy E. Cohn is at Berkeley on vacation from Minas del Tajo, Rosario, Mexico.

William Scallon has removed from Butte to New York and is at 55 Liberty street.

W. A. Prichard has returned to Santa Cruz de Alaya, Mexico, from San Francisco.

Wilbur H. Grant, of Spurr & Cox, was in San Francisco en route from Tacoma to Tonopah.

W. Randolph Van Liew has been appointed general manager for the Caucasus Copper Co., Limited.

Edwin Letts Oliver has established offices for the Oliver Continuous Filter Co. at 9 First street, San Francisco.

Frank W. Royer, consulting mining engineer, has established an office at 522 Mutual Life building, Mexico, D. F.

Frank H. Probert, of Los Angeles, returned to Globe, Arizona, from New York, and went from there to Chicago.

C. Colcock Jones has returned to Los Angeles from a professional trip of several weeks in Esmeralda county, Nevada.

R. B. Wheelock has resigned as engineer for the Quartette Mining Co. at Searchlight, Nevada, and will open an office at Battle Creek, Michigan.

J. D. Irving, editor of *Economic Geology*, is attending the International Congress of Geologists in Sweden. W. S. Bayley, of Urbana, Illinois, is editing the journal in his absence.

A. V. Judson has resigned his position as superintendent for the Mt. Pleasant Con. G. M. Co., at Grizzly Flats, California. His temporary address will be 2103 San Jose avenue, Alameda, California.

W. B. Cogswell, of the Solvay Process Co., is returning from a motor trip on the Continent and an outing on the Mediterranean; sailing a few days since for New York City from Genoa, Italy.

S. E. Bretherton returned to San Francisco from Shasta county, where he was starting work in the mines of the Afterthough Copper Co., and has gone to Plumas county to examine drift and quartz mines.

Carl F. Dietz, of the firm of Dietz & Keedy, of Boston, sailed for Europe on professional business during the week and also will attend the joint meeting of the Mechanical Engineers at Birmingham and London, thereafter going to Paris and Berlin on business for his firm.

The San Francisco Section of the Mining & Metallurgical Society of America held a field meeting at Grass Valley and Nevada City, July 22 to 24, the visiting members and guests being entertained by George W. Starr and A. D. Foote. Among those present were S. B. Christy, A. D. Foote, Corey C. Brayton, Whitman Symmes, William Hague, F. L. Sizer, C. C. Broadwater, George W. Starr, E. A. Hersam, C. C. Derby, Arthur Foote, Albert Burch, J. F. Farrell, and H. F. Bain.

Recent Publications

SURFACE WATER SUPPLY OF THE UNITED STATES, 1907-8. Part III. Ohio River Basin. By A. H. Horton, M. R. Hall, and R. H. Bolster. U. S. Geol. Surv., Water-Supply Paper 243. Pp. 224, ill., index. Washington, 1910.

PROGRESS OF THE MINERAL INDUSTRY OF TASMANIA. By W. H. Wallace. Pp. 11. Hobart, 1910. The usual report for the quarter ending March 31, and showing a total production valued at £344,766.

MINERAL RESOURCES OF THE NABESNA-WHITE RIVER DISTRICT, ALASKA. By F. H. Moffitt and Adolph Knopf, with a section on the Quaternary by S. R. Capps. U. S. Geol. Surv., Bull. 417. Pp. 64, ill., index, maps. Washington, 1910.

An instructive little hand-book descriptive of the region southeast of the headwaters of Copper river.

MARYLAND GEOLOGICAL SURVEY, Vol. VIII. W. B. Clark, State Geologist. Pp. 486, ill., maps, index. Baltimore, 1909. This elaborate report includes three parts: (1) Second Report on State Highway Construction, by W. W. Crosby; (2) Maryland Mineral Industries, 1896-1907, by W. B. Clark and E. B. Matthews; (3) Report on the Limestones of Maryland, by E. B. Matthews and J. S. Grasty. The volume is another welcome addition to the series being published by Mr. Clark and his associates.

CONTRIBUTIONS TO ECONOMIC GEOLOGY, 1909. Advance chapters from the annual bulletin of the U. S. Geological Survey are now available as follows: Copper, by L. C. Graton, H. S. Gale, and G. W. Stose, Bull. 430-B; Lead and Zinc, by L. J. Pepperberg, Bull. 430-C; Iron and Manganese, by E. C. Harder, J. L. Rich, A. C. Spencer, and Sidney Paige, Bull. 430-E; Mineral Paints, by J. C. Stoddard, A. C. Callen, F. T. Agthe, and J. L. Dynan, Bull. 430-G; Salines, by C. L. Breger and A. R. Schultz, Bull. 430-I.

TRANSVAAL CHAMBER OF MINES TWENTIETH ANNUAL REPORT, FOR THE YEAR 1909. Pp. 511. With a supplement separately bound containing a list of companies, syndicates, etc., registered in the Transvaal, pp. 86. Johannesburg, 1910. The work of the Transvaal Chamber of Mines is well known and the annual report of that organization has come to be regarded as one of the indispensable volumes of the year. The last report is no less valuable than its predecessors and is a compendium of all the business features of mining on the Rand. Labor, titles, laws, taxes, patents, output, and similar matters are discussed with a wealth of detail quite unequaled elsewhere.

THE GOLD HILL MINING DISTRICT. By F. B. Laney. North Carolina Geol. & Econ. Surv., Bull. 21. Pp. 137, ill. Raleigh, 1910.

The Gold Hill mines were discovered in 1799 and have been frequently described, though not with the wealth of detail afforded by Mr. Laney's monograph. By using a metallographic microscope he has worked out successfully the relation of the sulphides to each other and the relation of the gold to the sulphides. The ores are found to consist of auriferous pyrite and chalcopyrite, with which is more or less gold-bearing quartz. The gold increases as the copper decreases, so that it is thought to be associated rather with the pyrite than chalcopyrite. The report is an example of the excellent work now being done by some of the State surveys.

SOLUTION OF GOLD IN SURFACE ALTERATION OF OREBODIES. By Albert D. Brokaw. Re-print from *Journal of Geology*, May, June, 1910. Pp. 321-326. In this paper are given the results of an important series of tests carried out at the suggestion of W. H. Emmons and leading to the following conclusions: (1) that at the dilution of natural solutions of ferric salts, their solvent effect on gold is probably slight; (2) that in the presence of manganese dioxide no increased solubility is found unless chlorides are present; (3) that mixtures of ferric sulphate, sulphuric acid, and sodium chloride in concentrations common in mine waters will readily dissolve gold in the presence of manganese dioxide; (4) that free hydrochloric acid in the presence of manganese dioxide has a much greater solvent effect than the same amount of chloride in ferric chloride solution; (5) that the influence of ferrous salts in suppressing the solubility of gold is negligible if manganese dioxide is present; (6) that the solution of gold is practically limited to the oxidized zone.

Book Reviews

Any of the books noticed in this column are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

THE FLOW OF WATER. By Louis Schmeer. Pp. 228. D. Van Nostrand Co., New York. Price $3.

This is a new treatment of an old and much discussed subject, in which the author has endeavored to present his ideas in as simple a manner as possible. It deals with the flow of water in conduits under pressure; in open conduits (cemented ditches, sewers, and the like), and in ditches dug in earth and rock, in all their varied shapes. It contains the necessary mathematical formulas, which have been simplified as far as possible, and explained in clear, comprehensive language. There are also many pages of useful tables to be employed in calculations, and which will make the book useful to the student of hydraulics and to the engineer.

THE CHEMISTRY OF CYANIDE SOLUTIONS RESULTING FROM THE TREATMENT OF ORES. By J. E. Clennell. Pp. 202. McGraw-Hill Book Co., New York. Price $2.50.

In the preparation of this volume the author has reviewed cyanide practice generally and has presented various methods by means of which the constituents of cyanide solutions may be determined at any period of the operation of the process. This is something which will appeal to cyanide operators generally, particularly where it is desirable to make tests in the daily routine of work, where absolute accuracy is not essential, the object being rather quickly to arrive at information which will be a guide to the operator in the conduct of the work from day to day, or as often as necessary. The book is one which will find a ready demand, and will make clear many of the problems that vex the cyanide metallurgist, particularly those less experienced in the business.

MANUAL OF THE CHEMICAL ANALYSIS OF ROCKS. By Henry S. Washington. Pp. 200. John Wiley & Sons, New York. Price $2.

This is the second edition of this excellent and popular book, which is now presented in amplified form. It deals with the constituents of rocks, and the apparatus, reagents, and methods for their determination. Throughout the work has been thoroughly revised and where necessary new details added, its object being to place scientific petrology upon a firm chemical basis. It cannot fail to be of value to the students of this interesting and important branch of chemical investigation.

The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

E. L., Rossland, B. C.: Hornblende granite.

A. C. A., Johnsonville, California: Pyroxenite.

E. E. M., Nogales, Arizona: No. 1, a highly silicified metamorphosed rock, probably of igneous origin; contains pyrite and chalcopyrite; No. 2, appears to be from the surface of No. 1, the sulphides being oxidized. The fragments are too small for accurate determination.

TABLE OF CONTENTS

EDITORIAL

PATENT laws in Australia have been changed in the last year and a lower scale of fees now obtains. In addition but two instead of seven copies of all drawings are now required, though the other five must still be furnished if called for.

STRANGE as it may seem, Colorado has a new mining camp, Beshear, five miles west of Georgetown, one of the oldest mining towns of the State. A townsite has been surveyed and 200 claims located. The discoveries were made by miners from Cripple Creek.

EUROPEAN visible supply of copper was estimated July 18, by James Lewis & Son, at 102,659 long tons, nearly double the stock on January 1, when it amounted to 55,677. European consumption for the first half of 1910, except in Germany, where the figures cover five months only, was placed at 145,527 tons of fine copper.

JAPANESE continue to leave the United States for home, the net excess of arrivals in Japan in two and a half years being 8600. The present arrangement regarding immigration of laborers to the United States seems to be working satisfactorily, and a problem that at one time threatened serious friction has thus been solved by the application of a little common sense.

THE PINE CANYON smelter of the International Smelting & Refining Company in Tooele county, Utah, is about to begin work. The first furnace was fired July 28 and actual smelting will follow as soon as the furnace and stack become thoroughly warm. The International is the most prosperous of the various Cole-Ryan enterprises, and with the new plant in operation should make even larger profits than those reflected in the present 2 per cent quarterly dividends.

'BACK TO THE LAND' is the cry that best meets the questions raised by the increased cost of living, and back to the land a steadily increasing stream of people is moving. During the panic of 1907 land dealers in Denver did a steady business, and in a surprising number of cases purchases were paid for in cash that had evidently been hoarded. Last fall under the auspices of the *Chicago Tribune* a land show was held in the City by the Lake, a show that proved surprisingly popular and started many away from the crowded cities. This autumn a similar exposition is to be held in Pittsburg, the *Gazette-Times* and *Chronicle-Telegraph* standing sponsor. Such movements warrant support. It is perhaps a matter

of individual preference, since we must rise early in any event, whether we do so to catch a suburban express or an unruly cow that has strayed to the far end of a dewy and briar-covered pasture. Whether it is easier to keep a cook in town or a 'hired man' on the farm is an open question. In irrigated districts fruits thrive, but so do mosquitoes, and many a man of sound judgment in business matters, prefers a beer garden to a market garden. Still, however we may look on these matters individually, there is no dispute that as a nation we need more men on the farm, and miners approve heartily all efforts to induce others to raise more foodstuffs.

MINE-RESCUE cars are being built under the direction of the new Federal Mining Bureau. Two have been ordered, one to be stationed at Billings, Montana, and the other probably in Utah. Each will be fully equipped with rescue apparatus and in charge of a competent officer prepared to respond to emergency calls for aid. This is an excellent move. Ultimately the mine-rescue work must be taken up by the States or by associations of mining companies, but for the present there is a large field of activity for the Federal officers in developing and demonstrating the proper methods and apparatus.

CURTAILMENT of the copper output seems actually under way, though having in view the Sherman anti-trust law, each company is acting 'individually.' Apparently the law of supply and demand has not been repealed and the companies find it unprofitable to continue to produce in excess of market requirements. Curtailment is sensible and business-like, and the public has no occasion to quarrel with it. It does not necessarily forecast any further move in the direction of the much discussed copper merger, though it is clear that leading copper producers are constantly being brought closer together by the logic of events.

LOS ANGELES is to have a systematic collection of rocks and ores illustrating the economic geology and mining industry of the tributary region. The matter has been undertaken by the Chamber of Mines and placed in the hands of a committee, of which Mr. J. Nelson Nevius is chairman. Space in the Germain building has been secured and a part of the material is already on exhibition. It is proposed that the collection shall be systematic. Earnest effort is being directed toward making it also truthful and representative. Donations are requested and will be installed and exhibited free of expense, provided that they conform in character to the very reasonable regulations adopted by the committee. The educational value of such collections is unlimited. A well arranged and well displayed collection gives to each visitor a large amount of information in a short time and a basis for correlation of other data derived from reading or conversation. Just as a bit of mineral put in a saturated solution will cause the previously invisible dissolved substances to become apparent by crystallization, so a visit to a museum will orient a vast amount of amorphous information. The specimen in the museum gives the student a starting point and a measuring rod. It makes knowledge practical and effective. For this reason museums are proper objects for public support. The industrial importance of systematic and attractive displays is better understood but still needs emphasis. Southern California, as other parts of the West, needs development, and one of the most effective means of bringing that about is to stimulate interest by such displays illustrating undeveloped resources. The Chamber of Mines has done well to take up the matter, and if the plans of the present committee succeed the result will be an effective agency for publicity of the right sort.

RECENT discovery of rich ore on the 1000-foot level of the Central Eureka mine, at Sutter Creek, California, again emphasizes the advisability of thorough prospecting during development. The Central Eureka was reopened in the early nineties after an idleness of many years. A shaft was sunk in the fissure, but no ore of consequence was found above 1100 feet from the surface. From the next level downward for 1200 feet the vein was extensively stoped and many dividends paid, but owing to increasing cost of operation and legal complications work was eventually discontinued. The mine remained idle until last year when it was reopened. Work has been principally confined to straightening and re-timbering the shaft. Now prospecting has revealed a new shoot of ore where little was expected. It was less than two years ago that in the South Eureka mine, adjoining the Central, a rich vein was discovered in the west country after many years of unprofitable operation on another vein, and the levying of 58 consecutive assessments. Mining on the Mother Lode in California, while no longer 'in its infancy,' still possesses many attractive possibilities.

Settlement of Illinois Labor Difficulties

That coal mining was about to be resumed in Illinois appeared probable at the first of this week. Since then returns from the referendum vote of the miners have made it clear that the suggested compromise will be rejected. It is entirely unlikely, however, that the mines will be idle much longer. The time when there is a natural and active demand for coal in the Middle West is at hand. The suspension has continued since April. This has given about the normal number of days of idleness for the year, and with the return of fall and active demand for coal, the mines must be re-opened or severe loss and hardship incurred. Neither men nor operators are in position to meet these, though both have probably been not unwilling to while away the summer in impressing the other fellow. The actual settlement proposed, and which doubtless nearly outlines the terms that will be finally accepted, involves an advance for the miners in certain districts over and above the terms of the Cincinnati demands. The troublesome shot-firers matter is compromised, the operators agreeing to assume payment provided the cost be limited and the shot-firers protected from Union control or interference. The operators are to

return to the Inter-state Conference and provision is made against calling out engineers, pump-men, and others essential to the protection of the mines not only during the life of the agreement, as provided by the old contract, but subsequently. To insure this, jurisdiction over the men concerned is given to the National rather than State organization of the miners. It is this slap at the State officers, apparently, that has aroused opposition and will necessitate further negotiation.

To mining men away from Illinois the significant facts about this settlement are that after a trial of independent negotiations the operators find it preferable again to become parties to an inter-state agreement, and the further fact that after repeated conferences with Mr. J. H. Walker and other State leaders of the Union had failed, the settlement has been negotiated by Mr. T. L. Lewis, the International president. That the local men are not yet ready to accept the settlement as a whole does not detract from the fact that the broader view of Union officials outside the State has proved helpful. A further noteworthy fact is that the matter is reaching adjustment by negotiation between the parties in interest, the operators and the men, and not through the services of outside arbitrators. More and more labor contracts are coming to be looked on as business matters pure and simple. Each side strives to get as much as possible and business conditions control the final settlement. We have faith in both the Coal Operators' Associations and the United Mine Workers, and we believe that the approaching affiliation of the latter with the Western Federation of Miners will bring to settlement of vexed labor problems in the West the benefit of experienced and capable negotiators and should be encouraged.

Oil-Land Legislation

Discussion of oil-land legislation is not now active. The great increase in output has set producers skirmishing for markets rather than wells. In California, where legislation regarding public oil lands is of first importance, everyone swears at the Lakeview gusher—and wishes he had one. Producers are divided. Those owning the fee to land, are, in view of market conditions, satisfied with the withdrawal orders of the President, since their present interest lies in checking rather than stimulating development. Temporarily, the interest of the conservationists lies in the same direction. To force development at present would lead to waste and unprofitable business for everybody. Withdrawing land from entry is an effective means of checking development. No other has yet been found except through monopoly of transportation and regulation of price. The operators or would-be operators, who do not own land, but were relying on 'locations,' are not so well satisfied with the situation. Many of them are deserving of sympathy, but more are not. On another page we present a careful account of the actual operation of the old law, by Mr. Forstner, a candid and experienced engineer who writes from the fullness of personal observation. The facts that he presents warrant careful study. It is clear that many claims were not entered in good faith, and it is equally clear that the field is not one where a plea may be properly made for the poor prospector. In California, where the oil sands lie deep and a valid discovery necessitates an expenditure of some $25,000, it is evident that the man who stakes a claim without means of developing it is a burden on the industry rather than a help. The situation is not the same as in gold and silver mining, where the patient and intelligent effort of the lone wanderer over the desert and mountains results in actual discovery of a vein. The oil industry differs so widely from metal mining that it is the height of folly to attempt to apply to it laws framed for the development of gold placers.

Defenders of the old law belong mainly in two classes, the first being those who expect to profit personally by the location of oil lands, but who, usually, do not have the means to develop a lease. These men fear, and properly, that under any leasing system requirements of work would be so severe as to prevent holding ground long enough to promote a company. The promoter, it may be promptly conceded, while occasionally malodorous, none the less serves a useful function in business economies, and must be considered. It is easier to raise money for drilling when definite bodies of land are controlled and a permanent title is in prospect, than to first raise the money and then find the land on which it can be spent to best advantage. This is true however much better the latter method may really be. The second class of objectors is one that deserves less consideration, though actually more influential. It includes the lawyers in and out of Congress who wish to let well enough alone and who look to further departmental and court decisions to clear away existing difficulties. Their attitude comes from a very accurate knowledge of and wholesome respect for the unsettling of conditions produced by any new law. Decisions rest largely on precedents, and these, like the miner's dependent shots, hang one on the other. A change in the statutes disturbs the whole equilibrium and re-opens many old contentions. It often requires re-fighting old battles, and the wisest lawyer cannot tell the final decision until the Supreme Court has spoken. Knowing the interests involved and the difficulties to be faced, the lawyers are always conservatives when a change of statutes is proposed. Lawyers, however, should serve the law rather than master it. Theirs is the duty of pointing the way and determining rights under the law. In making the law they have only the rights and responsibilities of other citizens. There are limits beyond which it is not wise to attempt by court construction to amplify an inadequate law. Temporarily there is joined to these classes a third, including those who, owning a fee in oil lands, and fearing the effect of additional development on prices are content with things as they are. What the outcome will be cannot be foretold. The situation is sufficiently serious to warrant careful study by all citizens. At the Los Angeles meeting of the Mining Congress a day will be devoted to the discussion of these and related problems. Certainly no more important topic could be chosen.

A Portable Saw-Horse Crane

By Corey C. Brayton

The crane, shown in Fig. 5, is simply a big saw-horse mounted on mine car-wheels and provided with a trolley. It was designed by myself, is original as far as I am concerned, and was improvised for installation of equipment at a mine of which I had charge. It differs in general from the common hand-operated crane only in that the floor of the building rather than the walls support it, and in that it is, to an extent, portable. The equipment at the mine where the crane was built, was electrically driven, all in one building, and consisted of a 140-hp. hoist, a 1000 and a 500-cu.ft. compressor. It was essential,

Fig. 1. Crane and Bed-Plate of Hoist.

Fig. 2. Crane Carrying Ore-Hoist Drum Weighing 6000 Pounds.

knowing the life of the property, to construct as light and cheap a building as possible, and it was desired at the same time to provide a means for installing the equipment and for taking care of repairs. A crane with a span equal to the width of the building and supported by the walls was obviously out of the question. A trolley for each machine supported by the roof and walls was not only out of the question, but also undesirable on account of having but one horizontal line of travel. The saw-horse crane was therefore designed, and the building constructed of the lightest possible framing.

The crane was built for a maximum load of 6000 lb., which was the weight of the heaviest single piece of machinery, and with a span a few inches greater than the width of the widest machine foundation. The arrangement of machines to avoid waste of floor-space necessitated a crane track for each. These rails were spiked to the floor joists before the double floor was laid, and the top of the rail is practically flush with the floor surface and out of the way. Owing to delay in delivery of material the installation was made before the completion of the building, as is shown by two photographs, Fig. 1 and 2. The electric wiring is under the floor and is therefore out of the way of both the crane and the employees.

The crane cost complete, without chain block, $100. The weight is approximately 2000 lb. The material entering into its construction, with the exception of the timber, came from the usual scrap pile found about a mine. The crane handled the installation entirely satisfactorily, and with a great saving in both labor and time. It can still be used in handling heavy pieces while making repairs. For installations of this kind and occasional repairs, it accomplishes exactly the same result as the hand-operated crane; that is, the placing of the load where it is

Fig. 3. Interior Showing Hoist, Switchboard, and Light Construction of Building.

Fig. 4. The Two Compressors and Crane.

wanted, is practically as efficient, and is much cheaper. It is far superior to the fixed trolley with only one horizontal line of travel. Fig. 3 and 4 show the machinery in place, and in Fig. 1 is seen the crane standing on the track.

The crane is easily and cheaply built, is readily moved when loaded, requires no extra strength in roof, walls, or floor of the building to support it, and pays for itself even in small installations and repairs. On account of its portability it can be made to serve several machines in the same building. At a small additional cost it could be built to handle double the load and could also be provided with means to facilitate the two horizontal movements of the load.

In general, mining machinery, such as hoists and compressors, is installed by a swarm of men using main strength, rollers, jacks, and pinch bars, with occasionally the aid of a chain-block suspended from shears, temporary frame work, or some other fixed support, and heavy repairs are made in much the same way. Such work is not only expensive and

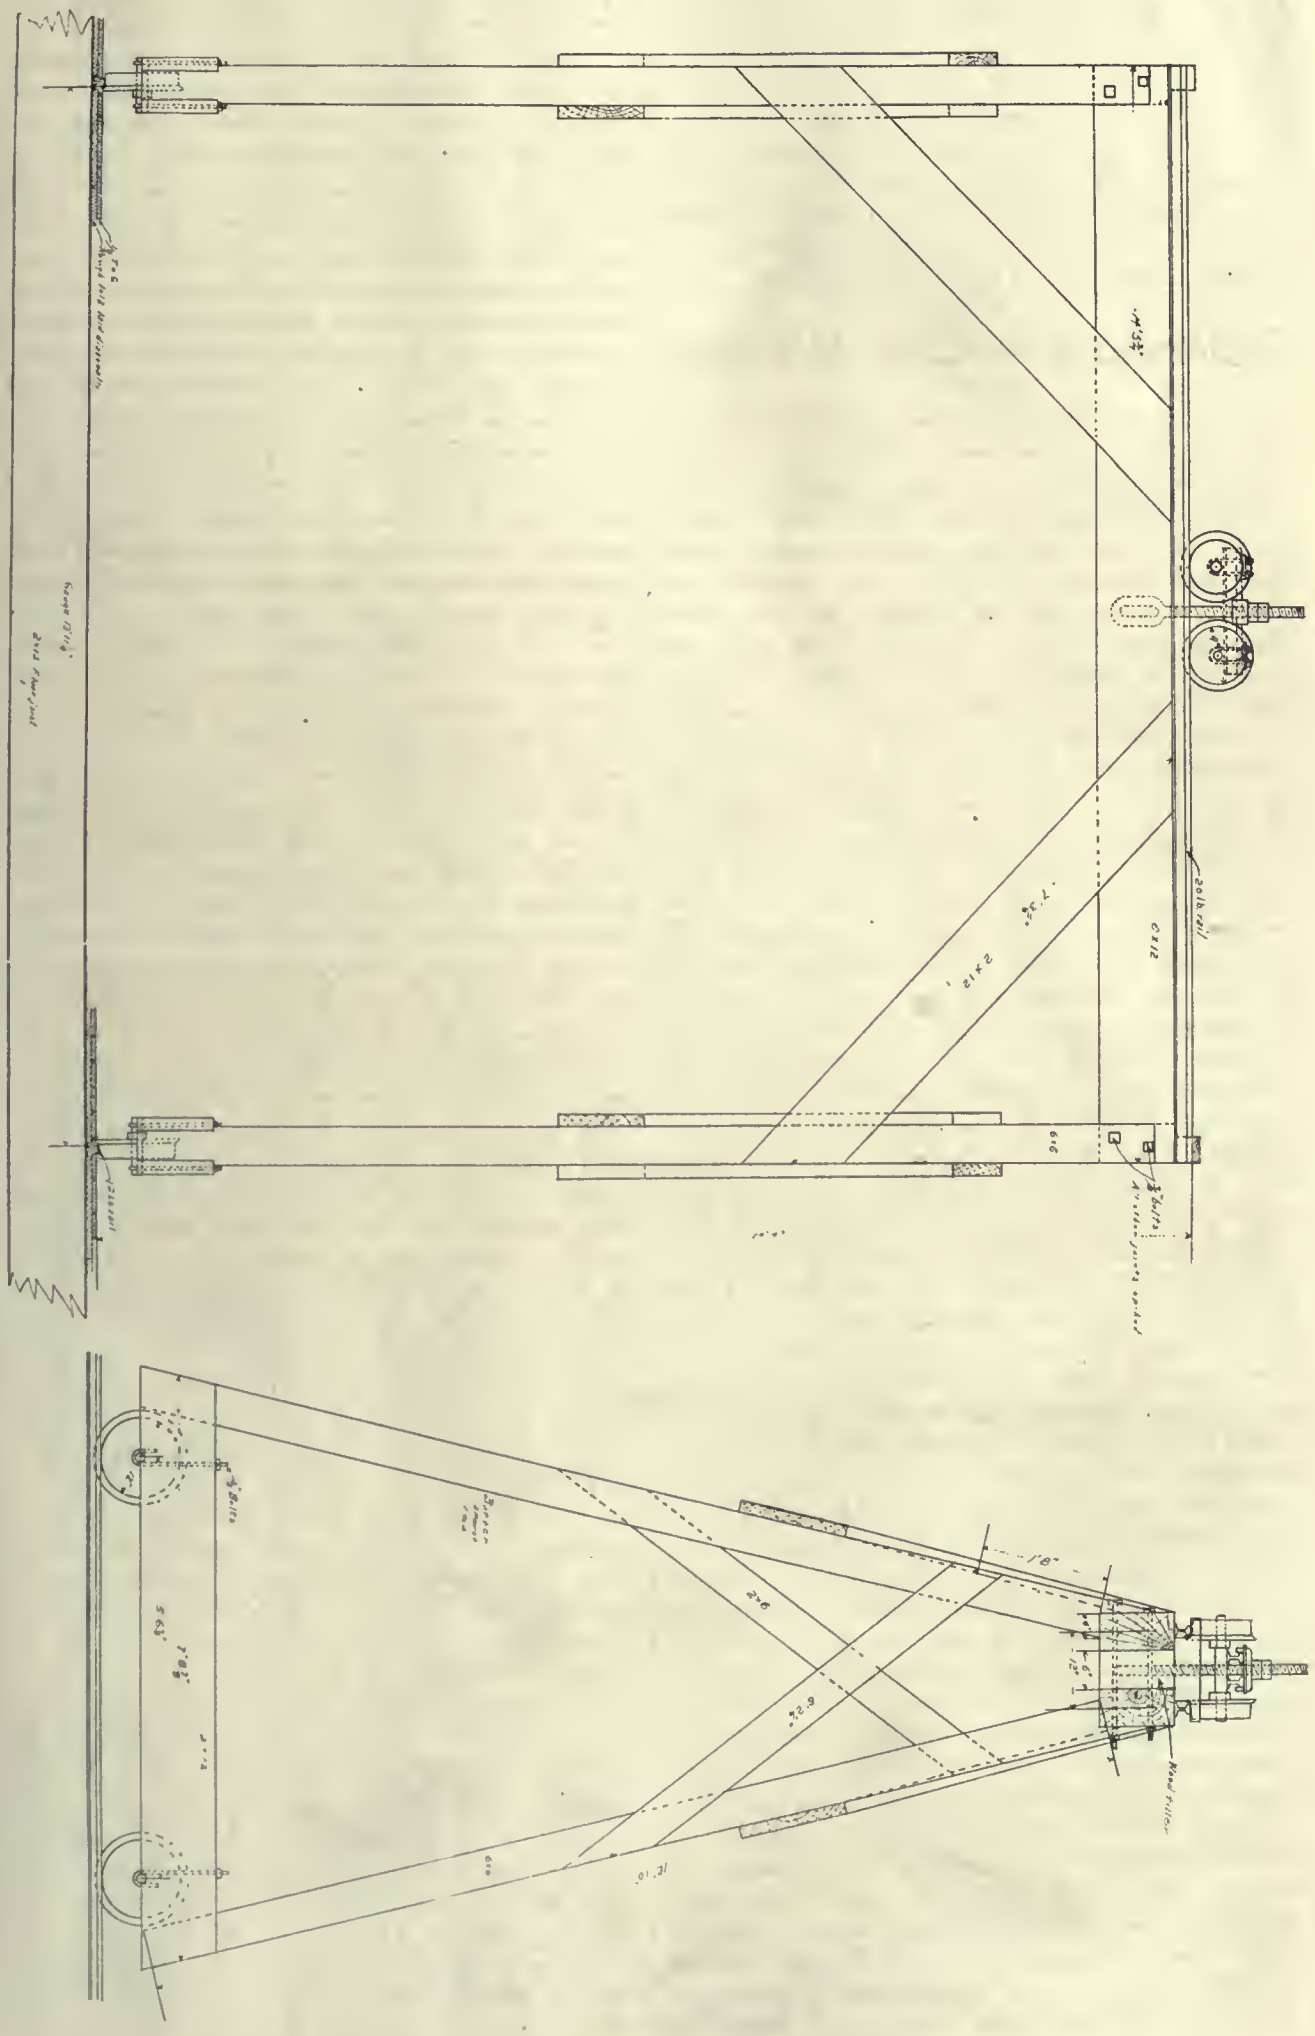

Fig. 5. Dimension Drawing of Crane.

slow, but also offers a considerable chance for breakage through accidents. This crane can be adapted to nearly all ordinary mine-machinery installations and repairs, and to a great variety of other machinery installations and repairs. In certain cases, of course, character of installation, frequency of repairs, weight of machines, or permanency of installation and building, warrant a trolley, or some type of overhead crane. There are other uses to which a cheaply constructed contrivance of this kind can be put.

Radersburg District, Montana

Recent developments in the mining district of Radersburg, ten miles southwesterly from Toston, in Broadwater county, Montana, has for the past year been attracting attention. Radersburg is an old camp, which forty years ago was being worked vigorously and with profit, the ores of the oxidized zone yielding $40 per ton and upward, in stamp-mills. With the penetration of the sulphides at about 100 ft. from the surface the ore was found to be no longer amenable to simple amalgamation, and as one mine after the other reached the region of sulphides, the activities of the district waned. It was at Toston that W. Lawrence Austin made his first attempt at pyrite smelting; an attempt that fell only a little short of commercial success. After all these years capital has again been interested and a new period of prosperity has come. The accompanying map shows the location of the important mines of the district. The principal work has been done in low foothills southwest of the town, 4500 ft. above sea-level. As usual in the West, the first mining was for placer gold, the production of which probably amounted to several hundred thousand dollars. Quartz mining began in the '70s on the oxidized ores. In recent years sulphide ores of the camp have been in demand by the smelters at Butte and East Helena, and the resulting low treatment rates have encouraged renewed activity in the district. At present several companies are operating and the camp gives promise of becoming a steady producer.

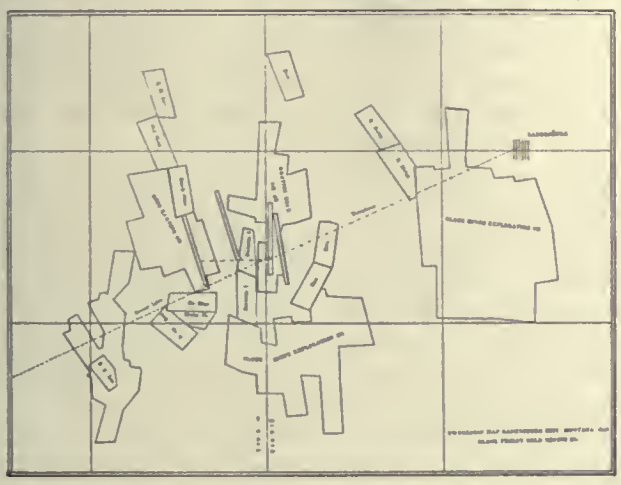
The Keating Gold Mining Co. is the largest operator. It has a vertical shaft 350 ft. deep, and an inclined shaft, on the vein, about completed to a depth of 600 ft. The property is being equipped for a production of 100 tons and over per day. The Black Friday Gold Mining Co., the next largest operator, has an inclined shaft 500 ft. deep, which is soon to be sunk deeper. The property is being equipped for a production of 30 to 50 tons per day. The Ohio-Keating, Rena, and Etta properties are in the development stage.

The Radersburg ores are found in narrow fissure veins in eruptive rocks. The veins strike north-south, usually, and dip steeply to the west. They are little faulted. The unoxidized vein-matter consists of auriferous pyrite in a gangue of calcite and quartz. Chalcopyrite, sphalerite, galena, marcasite, pyrrhotite, and chalcocite occur rarely. Fourteen miles west of Radersburg is the Elkhorn district, and the eastern edge of the batholith of granite, in which occur the Butte ore deposits. At Elkhorn is found a stratigraphic section extending from the Algonkian to the Cretaceous, occurring as the west side of a synclinal fold with north-south axis. Passing east, toward Radersburg, the syncline is succeeded by a well developed anticline across which a section is exposed down to the Algonkian and up again from Algonkian to Cretaceous, and into Tertiary strata (Bozeman lake-beds). On the east side of this anticline, at the horizon of the Cretaceous rocks, is found the Radersburg mineralization. An extensive zone of igneous rocks breaking through Cretaceous shales, sandstones, and limestones, occurs here, trending northerly and southerly, and extending for at least twenty miles. These rocks consist of diorite, andesite, with less abundant felsite and rhyolite. The mineralization occurs in these igneous rocks, or associated with them. The geological relations of the igneous rocks are complicated and have not been worked out. Some of the andesites and felsitic rocks may be surface flows, though most of them appear to be intrusive. Secondary enrichment of the oxidized ores is not marked. A ton of oxidized ore may be richer than the underlying sulphide, but this can be accounted for by the fact that it takes about twice the volume of the oxidized ores to make a ton as it does of the sulphides. There is no indication of decrease of value in the veins to the present depths. In fact, the Black Friday ore-shoots appear to have increased in size and value with depth. Tertiary lake-beds conceal the underlying rocks over much of the district. In these lake-beds numerous hot-spring deposits occur. The veins of these hot-spring deposits are calcite veins, having usually the same strike and dip as the productive veins. By following the strike of some of the productive veins into the lake-beds the tufas of the hot-spring deposits are found. These facts suggest that the hot-spring deposits may represent a stage of the mineralization of the producing veins, as they both have the same gangue, namely calcite. Incidentally a unique question involving the mine location laws has been raised here. The hot-spring deposits contain sufficient gold to permit a valid lode location. The surface tufas spreading out from the hot-spring vents or veins are integral parts of the lode, though lying flat on the surface of the lake-beds; that is, the tufas are as much a part of the veins, in the light of their genesis, as are the vertical veins along which the solutions ascended. The question arises whether a location made on the surface tufas without exposing the vertical vents is valid. If so, the matter becomes complicated, since the tufa has the lake-bed clays for a foot-wall and the sky for a hanging.

The Ohio-Keating Con. M. Co. is developing a vein on the Ohio claim which is readily traceable on the surface for half a mile. It strikes N. 10 to 20° W., dipping a little to the west. The vein varies from a seam to 4 ft., averaging 16 in. The oxidized ores of the upper portion of the vein were little stoped years ago. It now has a 220-ft. shaft on the vein, with a drift at 110 ft., which runs north 216 ft. and south 37 ft. At the face of this latter drift the vein is displaced by a transverse fault, the throw being to the west. A large number of samples taken

in this drift and in the shaft indicate an average of $16.25 per ton, which is almost exclusively gold, in pyrite. Gangue minerals, quartz, and calcite occur in relatively small amount. A second shaft has been sunk 120 ft. north of that above referred to, to a depth of 45 ft., where some stoping has been done. Shaft No. 3 is 750 ft. north of No. 2, and here stopes have also been made by the old timers in the oxidized ore. The vein occurs in a series of lenses, the walls repeatedly closing the fissure to a seam and opening again to several feet. A remarkable and fortunate thing is noticeable in the fact that the wider places in the vein are the richer, the ore ranging in grade from $2.50 to $74.40.

A glance at the map will discover a number of long lath-shaped claims. These were located in early days when claims were 2200 ft. long and 100 ft. wide. One of these is the Keating claim of the Keating Gold Mining Co., on which the deepest shaft has been sunk 600 ft. A vertical shaft has been sunk 350 ft.



The longest level is 1250 ft. on a vein of solid pyrite, averaging $15.50 per ton. In one portion of the vein a stope has been opened continuously for a distance of 840 feet.

Another important development is found on the Black Friday vein, owned by the Black Friday Gold Mining Co. This vein is somewhat different from the other veins of the camp, in that the fissure is accompanied by a gouge in places, indicating a differential movement of the rock walls, that is, there has evidently been greater movement of the walls at those places where the gouge is present than elsewhere along the vein. To this movement is ascribed the fact that oxidation has extended to greater depth in the Black Friday than in the other claims, and the change from the oxidized zone to that of the sulphides is less abrupt. The enclosing rock is described as andesite, in which is noticeable numerous phenocrysts of feldspar, and the walls are impregnated to some extent with pyrite, and the jointing planes and fractures of the rock are similarly mineralized. The statement is made that since June, 1909, there have been shipped from below the 200-ft. level, 1150 tons of ore having a gross value of over $50 per ton. This vein, like the others of the camp, is narrow, in hard rock, and occurs as a series of relatively long flat lenses. Mining cost is estimated at $15 per ton.

The cost of operating in this district is variously estimated, the figures ranging from $8.75 to $20 per ton, including mining, transportation, and smelting. There is no doubt that the treatment of the ores of this district at the mines will be of great advantage in the economy of operation of these properties, and without doubt this will be done. The present impression is that fine grinding, roasting, and cyaniding will successfully treat the ore, and it may even be that the raw sulphides may be amenable to treatment by cyanidation, but of course this has to be demonstrated. The information contained above was abstracted chiefly from reports made by W. L. Creden and D. C. Bard, of Butte; C. W. Pritchett, of Denver, and R. B. Lamb, of New York.

Acquisition of Public Oil Lands

By William Forstner

During the last months numerous articles have appeared in various daily and weekly publications in California, attacking the withdrawals from entry of lands within the supposed belt of oil-bearing lands in California, ordered by the Government during the years 1908 and 1909. As the validity of these withdrawals is a matter of doubt, projects of law were proposed in Congress to cover this point, and these projects have found so much opposition among the oil men in California that a delegation went to Washington to protest against the adoption of any law validating these withdrawals. In fact, it appears that a large majority of the oil men desire to have the present mode of acquiring title from the Government to oil lands remain in force. Before entering into a discussion as to what would be the most desirable method of disposing of the probable oil lands still remaining within the jurisdiction of the Government, it appears to me important to place before the reader the former law and regulations under which oil lands were entered, and the practical result of their operation, and then the new law passed at the end of the recent session of Congress, to show what new conditions have been created by its enactment.

The act of Congress of February 11, 1897, stipulates that "any person authorized to enter lands under the mining laws of the United States may enter and obtain patent to lands containing petroleum, or other mineral oils, and chiefly valuable therefor, under the provisions of the laws relating to placer-mineral claims." Section 2329, Revised Statutes of the United States, stipulates that: "Claims usually called 'placers,' including all forms of deposit, excepting veins of quartz, or other rock in place, shall be subject to entry and patent, under like circumstances and conditions, and upon similar proceedings, as are provided for vein or lode claims." Section 2320, in prescribing the manner in which lode claims shall be located, contains the following: "but no location of a mining claim shall be made until the discovery of the vein or lode within the limits of the claim located."

That discovery of mineral is required to validate

a location has been so repeatedly held by the courts, that this point may be considered as placed beyond controversy. No title is then acquired by the mere act of locating an oil placer claim on vacant Government land, and no right of exclusive occupation on such a claim is obtained until the discovery of 'mineral,' (here oil), has been made on such claim.

This point is apparently lost sight of by those who claim that by changing the present method of disposing of those lands, the Government will deprive the poor prospector of the chance of making money. The intent of the law of May 10, 1872, and of the law of 1866, which it superseded, was undoubtedly to encourage development of the mineral resources of the country, not to retard it by allowing parties to locate large tracts of land without performing any development work, thus preventing others willing to develop the land from doing so, by exposing them to the chance of litigation after they have succeeded in proving the land valuable.

To protect his right such locator, or association of locators, must "with diligence prosecute the work toward a discovery." "To constitute such a discovery of oil by boring beneath the surface."—Miller *v.* Christman, 140 Cal., p. 440. Even then, in the same case, the court held that "the discovery, when made subsequently, operates to perfect the location against all the world, save those whose bona fide rights have intervened," and further, "where there is an absence of discovery of oil within a prior location, and no work is done to protect the possession of the prior locators, their location is void, and subsequent locators entering openly and peaceably in good faith, and making another location, which they proceed to protect by diligent prosecution of work to the discovery of oil in paying quantities, acquire a valid title as against the prior locators."

It will be seen from the above that under the former law, until the discovery of oil was made, diligent operation of the work toward a discovery was an essential requisite to protect the right of possession of the locator.

This was, however, entirely lost sight of by the great majority of locators. They assumed that the perfunctory performance of the annual labor of at least $100 worth of work, or improvements, prescribed by section 2324 of the Revised Statutes, was sufficient to hold possession of the located claim, not taking into consideration that discovery was a prerequisite to perfect their right of occupancy. This annual labor was also, in nearly every case, of the most perfunctory character, and consisted either in building a cabin, generally unfit for habitation, or the erection of a 'stub-derrick,' consisting of four short batterposts on blocks with light braces and entirely unfit for actual work, showing that the intent of these locators was not to perform the work required to discover oil, but solely to hold the claims at the least expense, with a view to disposing of their assumed rights to parties willing to do this work.

Undoubtedly a number of bona fide locations were made in the oilfields, but I believe to be well within the limits when I state that nine-tenths of the locations were not made with any intent to develop the land, but purely and simply with the purpose to prevent others from locating the land, and to force any party who actually desired to develop the land to pay them a sum of money, or to surrender them a part of the land after patent was obtained, which cannot be considered as otherwise than extortion, because those parties were not receiving any valuable consideration, but had to submit to this arrangement in order to enter into peaceful possession, while the locator had, in fact, not the slightest legal right to claim exclusive possession.

In order to show to what an extent this locating of Government land, without making any effort to develop the land so claimed, had been carried on, a list of acreages located by a number of groups of locators is given:

	Acres.
One group on January 1, 1908	39,040
Another group on " " "	4,480
" " " " " "	7,040
" " " " " "	6,400
" " in December "	3,280
" " on January 1, 1909	4,620
" " " " " "	1,920
" " " " " "	2,400
" " " " " "	3,040
" " in March "	5,920
" " " May "	4,840
" " " " "	4,320
" " " " "	3,840
" " " June "	2,560
" " " July "	2,640
" " " September "	18,240
" " " " "	3,640
" " " " "	3,520
" " " " "	3,840
" " on January 1, 1910	9,440
" " " " " "	6,400
" " " " " "	7,520

Nearly all these locations were made at a distance from existing producing wells, in territories where the actual underground conditions were unknown, and it is fair to assume that the average cost of a well under these conditions would be in excess of $25,000. As on every 160-acre tract one well had to be in actual process of development to answer the requirements of the law, it is clear that not one of these associations of locators showed a bona fide intent to proceed in the actual development of the lands they located. A great number of these locators cover the same lands: often as many as five and six locations have been filed on one quarter section. Many of these locations cover lands held by agricultural patent, or lands on which agricultural claims of various kinds—homestead entry, desert land entry, forest lieu selections and State selections—have been filed.

The uncertainty as to what rights any location carried with it was further complicated by the question whether when an association of eight locators have transferred their interests to another party, and this party, individual or corporation, makes a discovery, such discovery entitles to patent for the 160 acres containing the eight associated claims or only for the 20 acres forming the claim on which the discovery was made. Section 2330 of the Revised Statutes declares that no location of a placer claim made after July 9, 1870, shall exceed 160 acres for

any one person or association of persons, and section 2331 provides that after May 10, 1872, no such location shall include more than 20 acres for each individual claimant. In Cook *v.* Klonos, 164 Fed. 529 Oct. '08, the United States Circuit Court of Appeals held "when the scheme is used to secure an interest in a claim for a single individual in excess of the limit of 20 acres, it is plainly in violation of the letter of the law, and when all locators had knowledge of the concealed interest and were parties to the transaction, it renders the location void." In July, 1909, the Department of the Interior rendered a decision, H. H. Yard et al., 38 L. D. 59, holding that where eight persons made a location without a discovery, and seven of them transferred their claims to one of the locators, or to another person, and such locator or other person made a subsequent discovery, that in such event such discovery would be a new one, under which a location of 20 acres only could be made by the persons making the discovery.

Considering the chaotic condition in which the whole question of the title to oil lands, held by virtue of location, was at the time, which had been repeatedly called to the attention of the Department of the Interior by its different bureaus, it is but logical that steps were taken to effect a better regulation, which finally resulted in the land withdrawal act passed in the latter part of June, 1910, by Congress. See *Mining and Scientific Press*, July 9, 1910, page 59.

By section 2 of this act the rights of the various claimants are distinctly regulated. It confirms "a bona fide occupant of oil and gas-bearing lands, who at the date of withdrawal is in diligent prosecution of work leading to the discovery of oil and gas" in his rights "so long as such occupant or claimant shall continue in diligent prosecution of such work," and further, specifically, those who have initiated rights or claims upon such oil or gas-bearing lands prior to the passage of this act. The objections made against this act appear to me largely unfounded.

The main objection is that the Southern Pacific Railroad Company will be unduly benefited by its provisions, due to the fact that it owns through a large portion of the oil and gas-bearing lands in the San Joaquin valley, the uneven sections, and that by drilling those sections it will practically exhaust the oil supply of the entire territory. This argument has found a strong response due to the inimical state of mind of the public toward corporations in general. To bear out the contention of this argument, however, a much higher mobility must be attributed to the oil in the oil-bearing strata than is really the case. Such high mobility is assumed by some writers in public print, for instance, in a recent technical oil paper, critisizing the fact that in the withdrawal act similar rules were prescribed for both coal and oil-bearing lands, the statement was made that coal was stable in its location, in contradistinction to "oil which floats around." It is outside of the scope of this article to get into a technical discussion regarding the distance to which an oil-well drains adjacent territory; but while admitting that oil can and does move through the strata wherein it is confined, this mobility is relatively small, and the migration of the oil through the sand is not rapid enough to cause a depletion of the oil-bearing strata by a well at a great distance from that well. This fact has been repeatedly proved by operations in the field. Although there are no data to determine the distance from a particular well at which its influence ceases, which distance naturally depends largely upon the physical character of the oil sands, the assumption that a line of wells surrounding a section, would be able to drain an important portion of the oil contained within that section is not at all sustained by actually observed facts.

Another objection against the withdrawal law is, that it only protects the locator who is diligently prosecuting the work of development, and thereby crowds out the locator whose means prevent him from doing so. Drilling for oil is expensive, especially in unproved territory, and a locator or association of locators, with limited means, are therefore handicapped. But bearing in mind the state of affairs existing prior to the passage of this law, the frauds attempted under the former law, the efforts to hold large acreages, as above noted, also to get patents on large acreages of oil lands under the pretext of gypsum discoveries, it appears to me that this drastic measure to prevent the continuance of these practises was perfectly justified.

As already stated in the editorial of the *Mining and Scientific Press*, in the issue of July 9, 1910, page 36, this is only a temporary law, until an adequate law for the disposition of oil and gas-bearing lands, belonging to the United States, can be framed and passed by Congress. I have already discussed some of the principles on which, in my opinion, such law must be based, in my article critisizing the project of law offered by S. C. Smith, Representative from California; see the *Mining and Scientific Press* of July 10, 1909, page 52.

Phosphate rock in bulk is shipped in large amounts from the southern ports of the United States into Rotterdam, and while large quantities are re-shipped up the Rhine into Germany, the Dutch factories consume probably 60,000 to 70,000 tons per year. All of these phosphates are on the Dutch free list and pay no import duty. In the Netherlands there are several large fertilizer works, manufacturing for the home market as well as for export. Aside from the factories already in operation, a plant with an annual output of some 30,000 tons of prepared fertilizers is under construction and will be ready to contract for its supplies of Florida raw material by the end of the present year. While the products of Christmas Island, Panope, and other sources of supply in the Pacific seldom find their way into this market, the Florida exports nevertheless have serious competition to meet. Large deposits are being worked in Tunis and Algeria, a Dutch firm having an important concession there. These African phosphates seldom run better than 55 to 60% pure, while the best grades from Florida will go over 75%. Aside from the lower price due to lesser purity, the item of cheap labor at the mines and shorter ocean transportation is in favor of the African producers.

Concentration of Slime—I

By Edwin A. Sperry

INTRODUCTION

In considering the treatment of slime by concentration, there are many things which come up for discussion and comparison. Such a discussion necessarily commences with the methods employed in the work of crushing the ore and passes along through the various steps of the operation of preparation, to the final treatment of the slimed ore and the recovery of the metals in a marketable form. The subject will be discussed under five heads in their natural sequence. These heads are: (1) crushing and grinding; (2) sizing; (3) classification; (4) dewatering; (5) final treatment.

Crushing and Grinding.—While the word 'crushing' is employed in this heading, it will not be used in reference to coarse-crushing machines, such as rock breakers, but will be applied to those employed in reducing the ore to less than 30-mesh, 30 wire (0.02-in. or 0.5-mm. open space). Sizes coarser than this come under coarse concentration and are, therefore, outside the scope of this paper. A definite classification of the various sizes to accord with the different lines of treatment which can be applied, based on practical lines, may be made as follows:

1. **Coarse**, or that size which can ordinarily be treated by jigs and including from the coarsest down to 30-mesh, 30 wire (0.02 in. 0.5 mm. open space).

2. **Sand**, or that size which, passing 30-mesh, remains on 100-mesh, 38 wire (0.004 in. or 0.1 mm. open space). This size is readily treated on the common form of concentrator such as the Card or Wilfley.

3. **Fine**, or that size which, passing 100-mesh remains on 200-mesh, 45 wire (0.002 in. or 0.05 mm. open space). This size is readily treated on the Frue vanner, Wilfley slime table, Sperry slime table, and various other machines used for this purpose. The principal reason, however, for making this division is based on the speed of settling in a body of water. Ore particles between 100 and 200-mesh have an appreciable ponderosity and on this account will settle readily, and are easily separated from the finer size and easily treated.

4. **Slime**, or the very finest size. The term 'slime' means widely different things to different people. In previous discussions three distinct points of view have appeared: (1) The purely practical, according to which slime is considered to be that portion of the ore that is so fine as to make it unfit for treatment on the common forms of concentrators; this is ordinarily placed at minus 100 mesh, and the division is based on a dividing line between the different methods of treatment. (2) The second point of view occupies an intermediate position between the practical and technical. The definition here might be stated as including that portion of the ore which, on account of its fineness, requires considerable time to settle in a body of water. This, if stated in terms of mesh, might more closely approach 200, but this is merely relative and given as a matter of comparison. This definition is practical in that it recognizes a division between quickly and slowly settling particles, and technical in so far as it recognizes a condition beyond terms of mesh in which specific gravity plays but little part. (3) The last and purely technical, is one according to which the particles are of such fineness that they lose their individual integrity and, in combination with water, approach, if they do not merge into, the colloidal condition of a hydrate, which changes their form and nature.

In the following discussion, the intermediate position will be assumed as more nearly conforming to the conditions to be met in practice.

In the crushing of ore, one of two results is aimed at, one being the least possible production of slime, the other, the complete reduction of the ore to this condition. In the discussion of the various types of machines for crushing and grinding, the crushing action, as well as the machines mentioned as examples, will be given as nearly as possible, in the order in which they theoretically occur, beginning with those which would give the least proportion of slime, and ending with those which would be most efficient in the reduction of the entire amount to slime. They will be first discussed from as nearly a theoretical standpoint as possible, analyzing the action of the machines themselves, and they will be placed, as nearly as possible, in their natural order as regards practical results.

In theoretical order, it happens, the Huntington mill stands ahead of the Chilean mill but, owing to the inferior method of screening in the Huntington, the order will be reversed. This will be more fully dealt with later.

The subject of crushing will be first taken up under the separate heads noted below. The different crushing actions may be classified as follows:

CHARACTER OF CRUSHING ACTION RELATIVE TO THEORETICAL PROPORTION OF SLIME PRODUCED

Elemental crushing action.	Derived actions.
1. Projectile.	1. Pressure-impact.
2. Pressure.	2. Pressure-torsion.
3. Impact.	3. Impact-torsion.
4. Torsion.	4. Impact-grinding.
5. Grinding.	

These may be placed in order of theoretical production of slime, based merely on the action itself, but subject to change from modifying conditions arising from individual action of the machine as follows: (1) projectile—Marx mill; (2) pressure—rolls; (3) impact—stamps (California practice); (4) pressure-impact—Huntington, Wild; (5) pressure-torsion—Chilean mill, triplex rolls; (6) impact-torsion—stamps (Gilpin county practice); (7) torsion—disc-grinders; (8) impact-grinding—tube-mills, ball-mills; (9) grinding—cone grinders.

(1) **Projectile.**—This action is ideal for the disintegration of the ore as the resulting impact against the 'anvil' has simply a shattering effect. The shattering is naturally along the lines of cleavage and is nearly in conformity with crystalization. Several attempts have been made to adapt this principle but no thoroughly successful machine has yet been evolved. One machine of this type, however, has been recently presented which gives promise of good results—the Marx pulverizer. It is still experimental but shows points of interest.

(2) **Pressure.**—Rolls, in ordinary practice, exem-

plify this action as nearly as possible and stand at the head of the machines of this class. By the term 'ordinary practice' is meant the common type of rolls in contradistinction to high-speed rolls. These were run at so high a peripheral speed as to approach the action of impact rather than of pressure. Triplex rolls are placed in another class as will be explained later.

(3) **Impact.**—As rolls are an example of pressure action, so the stamps stand for impact. This contemplates the simple reciprocating motion without the rotating motion which is sometimes given them, especially in Gilpin county practice. This will be spoken of later. A distinction is made between California and Gilpin county methods. In the California mill stamps weigh approximately 1000 lb., drop 100 per minute, with height of drop 7 in., height of issue 2 to 4 in.* With these dimensions and speeds the delivery of pulp from the battery is rapid and as a consequence the removal of undersized particles is more thorough. Even with this rapid delivery there is much of the undersize which remains in the crushing zone but, owing to the rapid drop and consequently excessive splash, these will not readily remain on the die to be struck again. In feeding the stamps the proportion of slime can be influenced. If the feeding is high the ore is crushed against itself and is not so finely pulverized as it is when 'iron strikes iron,' as the expression is. Then, too, if plenty of water is used the undersized particles are the more readily washed out through the screen. By careful manipulation stamps can be made to crush very uniformly, with a small proportion of slime.

(4) **Pressure-Impact.**—In the Huntington, the Griffin, and the Wild mills, we have examples of this action. In these machines crushing is done on the inside of a large ring by the pressure, generated by centrifugal force; a muller in the form of a small cylinder rolling against the ring. In one form, the Huntington and Griffin, the ring and muller lie in a horizontal plane and the pressure is generated by centrifugal force. In the other form, the Wild, the ring and muller are in a vertical plane and the pressure is that of gravity. The compound action of pressure-impact is accorded these machines as the rolling-pressure action of the mullers is often combined with jumping of the muller, the return of which to contact with the ring develops considerable impact. This is due to the fact that the mullers are not rigid and are free to recede. In the first form the ore, after crushing, is thrown vertically and then, by vanes, horizontally to the screens. In the Wild it is thrown, at once, horizontally, to the screen. In comparing the two actions the difference in the efficiency of these mills, due to these causes, will be appreciated by millmen, the Wild mill conforming more nearly, if not quite, to the theoretical.

(5) **Pressure-Torsion.**—This action is shown in the Chilean mill and in the Triplex rolls. It is the result of rolling a short cylindrical-shaped body in a circular direction on the face of the disc or flat ring. As the muller is a cylinder, and not a cone, its line of contact with the horizontal plate is equidistant from its axis, and as this contact line is always radial to the disc, or ring, there is a constant twisting motion between the two surfaces. The weight of the rolling member in the Chilean, and the pressure of the spring in the Triplex rolls, with the torsional or twisting action described, give the 'pressure-torsion' combination. While these two machines are theoretically in the same class, the lower screening capacity of the Chilean places it below the Triplex in the practical order. The pure torsional action would be more highly productive of slime but as it is slight in both cases mentioned, it does not enter largely into the consideration of results. The Triplex rolls have the advantage of an immediate removal of the ore from the crushing zone and, as in the case of ordinary rolls, the undersize is isolated at once, nothing but the oversize being returned to the crushing zone, at least, such should be the case.

(6) **Impact-Torsion.**—Gilpin county stamps are used as an example of machine using this combination. In comparison with the California stamp the general form will be given. The stamps weigh 650 lb., drop 30 per minute, from a height of 17 in., with height of issue 10 to 15 in. Owing to the height and upward slowness of the motion of the stamp, the cam has an opportunity to give the stamp a spinning or whirling motion, and in descending it strikes the die with a twist. This gives the combination of 'impact-torsion.' The torsion is not great, but more than in the Chilean mill. The slow action of the stamp, together with the great depth of the issue, causes fine grinding which places it far down in the practical scale.

(7) **Torsion.**—There are no machines which use a strictly torsional action in crushing ore, the nearest approach to it being the disc grinder, composed of two discs revolving in opposite directions. The ore is fed at the centre between them. The discs are slightly dished in shape, that portion near the edge having parallel faces. They are so arranged that these faces are a certain distance apart and are set up when the wear increases the space. The circular motion of the discs gives a twisting motion which is most effective in crushing. This form of machine is not much used as the wear on the crushing faces is excessive and the power consumed is relatively large.

(8) **Impact Grinding.**—The tube or pebble mill, is used as an example of the application of this combination. The general form is a tube, ordinarily 14 ft. long by 5 ft. diam.; lined to protect the outer shell of the mill, usually with silica brick, or some such material. The tube is charged with several tons of rounded flint pebbles of 3 to 4 in. diam. The ore is fed at one end and the tube revolved. As the pebbles roll and fall down from the ascending side, the ore is caught between them and eventually ground into a slime, when it is discharged from the other end. The object of this machine is to reduce everything to slime and it is considered one of the most effective devices for this purpose. The ball-mill is a modification of the tube-mill with the substitution of steel balls for pebbles and steel lining in place of the silex brick. It is designed for dry

*The Gilpin county data will be given later.

grinding and is used extensively in cement manufacture.

(9) **Grinding.**—This action is exemplified in the ordinary sample or cone grinder. Its action differs from disc grinders in that the moving surface passes the fixed plates in practically straight lines, causing a simple rolling motion without torsion. It is so designed that by adjustment, the grinding surfaces gradually approach each other until they are in contact. This machine has no practical value in metallurgical operations outside of the laboratory.

With this short discussion of the various actions the comparisons of practical results can be more readily understood. It is an extremely difficult matter to make any specific statement as to what machine will produce the greatest amount of slime, for, to determine this point, it would be necessary to operate all of them on the same ore and under the same conditions. The only way to reach a conclusion is to analyze the crushing action and then, by a consideration of the manner in which the ore is delivered from the crushing zone, as regards its promptness, a fair idea can be gained as to its efficiency. One statement can be made which needs no argument, and that is, that it matters not what machine or what action is employed in the crushing of ore, the amount of slime produced is largely, if not entirely, influenced by the promptness and thoroughness of the removal of the undersized material from the crushing or grinding zone. From this point of view, and from this only, can proper comparison be made between machines of different type. Based on this statement, it can be readily assumed that rolls would produce less slime than stamps, even of the California type, and the Chilean mill less than the Huntington. As to the stamps and the Chilean, it would depend on the manner of operating the stamps. With proper use the stamps produce less slime. While the Wild mill uses the same crushing action as the Huntington, it can be placed ahead of stamps, owing to its prompt delivery, and it would be fair to suppose that the Triplex rolls would be superior to the stamps.

A general statement concerning the machines cited can be made, however, by placing them in one of three classes: (1) those best adapted to crushing without producing slime: (2) those which occupy an intermediate position and can be used for either purpose according to conditions; (3) those especially adapted to the reduction of all the ore, or practically all, to slime. They may be classified according to this plan, as follows:

1.	2.	3.
1. Rolls.	4. Stamps.	7. Disc-grinder.
2. Triplex rolls.	5. Chilean mill.	8. Tube-mill.
3. Wild mill.	6. Huntington mill.	

Many styles of crushing machines might be cited, but only those more commonly known have been used in comparison, it being more especially the present object, to define the various actions and results by reference to well known forms. From these it is hoped that analysis of action and results may be readily applied to such machines as may be met in special cases.

SIZING

Sizing is the separation of ore particles into classes having the same diameter, within a certain range, regardless of their specific gravity. Sizes are best specified by using two screen meshes. For instance, if it is stated that certain particles are 30-60 mesh, it is to be understood that they pass a 30 and remain on a 60-mesh screen. It is customary to designate a screen as '30-mesh' or '60-mesh' when from centre to centre of wires it is $^1/_{30}$ or $^1/_{60}$ of an inch. In other words there are 30 or 60 meshes to a linear inch. This term is indeterminate as the size of the wire has to be considered. In stating the size of a screen in terms of mesh it is always wise to designate the size of the open space and size of wire, as these are vital points. There is a method of designating screen sizes, which is coming into vogue, and by its use there is no chance for a doubt as to the space. It is the use of metric terms in designating the size of the open space direct. It should be encouraged, and were it not for the unfamiliarity of the public with the comparative value of the metric measurements, it would be more universally adopted.

There is no department in metallurgical work where there is so much confusion and misunderstanding as in the designation of sizes of screens. A great deal has been written on the subject, but there seems to be still room for some definite system of terms. The Institution of Mining and Metallurgy has put out a standard list, and for some few purposes it is commendable. In the presentation it stated that the design was simply for use in laboratory work in order that results could be based on some uniform system of sizes. It was based on a standard size of wire for each mesh, but it is obvious that this standard could not be carried into practical mill work and this fact was recognized by the Institute. The reason for this can be briefly stated. There is work in which heavy service is required of screens having the same open space as there should be in others which require as high a percentage of open area as possible. As an illustration the screen of a trommel needs to be heavy to insure a reasonable length of life. In the jig cell handling the oversize from this trommel the open area should be as great as possible and on this account lighter wire can and should be used. Other cases might be cited, but this will illustrate the point.

In the average mind the term '30-mesh,' or whatever it might be designated, has a specific value and all that is necessary is to order or specify by this simple and ambiguous method. At many of the larger mills this confusion does not exist, as all the screen lines are worked out on definite statements of 'open space.' Even then, there has been but little information to guide the designer or operator in the selection of screens which have the required weight and space for the purposes for which it is intended, in order to fulfil the conditions of the service it is designed to meet. There is no greater need of care in any department of milling than in the selection of a screen line, so designed that the particles may be sized within the most desirable range. A failure to select the most advantageous sizes and ranges has contributed, in many cases, most seriously to failure.

A fixed system of determining what open space is most efficient would be of great value to the designer as well as to the operator.

OPEN SPACE	64ths	25/64	23/64	20/64	18/64	16/64	15/64	14/64	13/64	11/64	10/64	9/64	8/64	6/64	5/64	4/64	2/64	1/64	1/128	1/256	1/512

WIRE SIZES REFERRED TO U.S. STANDARD LEGAL GAUGE

A table has been prepared which is herewith presented, in which the open space is given in sixty-fourths of an inch, in millimetres, and in decimals of an inch, starting from what is termed '2-mesh' and ending with '200-mesh,' under each head, giving size of open space. In one column several mesh values are given with the gauge number of the wire which would give the open space at the head of the column. For instance, in the column headed $^{2}/_{64}$—1—0.039, the open space would be $^{2}/_{64}$ in., 1 mm. or 0.039 in. Running down the column it appears that 14-mesh with No. 21 wire, 16-mesh with No. 23 wire, 18-mesh with No. 27 wire, or 20-mesh with No. 32 wire would all give the open space designated at the head.

With this table at hand, a line of screens may be readily and quickly worked out and the weight of the wire selected to meet the various services required. The wire in the larger sizes is calculated to $^{3}/_{1000}$ of an inch, which is as close as it could be approached in ordinary application or manufacture. In the finer meshes it is practically correct. Inasmuch as there is considerable of a variation between the several gauges it would be well to establish a fixed standard in this regard. There is but little difference between the English legal and the American legal standard gauge, and either could be used without materially affecting the results.

From the nature of the case, sizing is necessarily done by screens. It is only within the last few years that screening has been successful for sizes finer than 30-mesh, 30-wire. The shaking or impact screen has made it possible to screen successfully as fine as 100-mesh, 38-wire. Of this type are the Impact, Imperial, Wild, and Centripact screens. The Impact employs a simple upward 'bump' at right angles to the screen, which, as the screen is placed on a slope, gives the ore a toss and lands it a little lower on the screening surface. The Imperial has a combination of horizontal and vertical motions, and as the ore is tossed, the screen recedes horizontally beneath it so that the ore lands at a point lower down on the screening surface. The Wild has a swinging motion without a bump, and advances the ore by a series of tosses. On the Centripact screen the ore progresses from the centre to the edge of a circular screen by a series of tips imparted by a revolving ratchet. They are all open to a similar objection—the necessity of many wearing parts.

Another type of screen has been introduced which bids fair to take a prominent position. It might be called a washing screen, as the pulp is distributed over the surface of a moving screen and moved forward, to and under a spray which washes the undersize down through the screen, leaving the oversize to be discharged at the tail end of the machine. No agitation is needed in this type of machine, dependence being placed on the spray to remove the undersize. There are two forms in which this type has appeared, the first being that of an endless belt of screen-cloth having a slow, progressive motion, as in the Callow screen; the other being virtually an inverted trommel, screening from 'out to in' instead of from 'in to out,' as in the King screen.

J. M. Callow, of Salt Lake, thus describes the Callow screen: "The fundamental principle of this machine is a traveling belt of screen-cloth, over which the ore and its carrying water is spread by means of distributing aprons or feed soles. This belt of screen-cloth passes over the head and tail-rollers, and the belt is caused to travel continuously in a horizontal direction at a speed varying from 15 to 30 ft. per min., according to the nature and quantity of the material to be screened. These feed soles or aprons play a most important part in the operation of the machine, and its successful and proper operation depends in a great measure upon this feature, as well as on its proper construction and adjustment. It is with this that a preliminary sizing is done, for, as the particles, which are of all sorts and sizes, fall from the lip, the coarsest pieces, having the greatest trajectory, strike the screen at a point far ahead of the smaller ones, leaving a space behind free and unincumbered, which permits the free passage of the fine material and water. Simultaneously with this action the cloth is moving forward and the deposit of oversize is continuously removed from the separating or screening zone, and thus the machine continues to perform its function so long as it is kept moving and is supplied with the feed. Beyond the screening zone, the deposit of oversize is carried forward and passes under a shaking spray of clear water, where any remaining traces of slime or of fine adhering particles are washed off and pass through with the water from the spray into the undersize hopper beneath. Continuing, the oversize still clinging to the screen-cloth, passes in front of a small impinging spray which is situated about the mid-diameter of the front roller, and the oversize is there washed off the screen-cloth into the oversize hopper below."

Foresters divide all the oaks into two distinct groups—the white oak and the black oak group. One way of distinguishing the two is by the fact that the black oaks require two years to mature their acorns, while the white oaks take but one. The woods of the two groups of oaks are also structurally different. The true white oak, known to botanists as *Quercus alba*, is merely one of the species which make up the white oak group. Red oak, on the other hand, belongs to the black oak group. Red oak has a number of common names, among them mountain oak, black oak, and Spanish oak. There is much confusion in the use of names of the oaks.

Diamond Mines of Arkansas

By John L. Cowan

If it were announced, upon unquestionable authority, that diamonds had been discovered in probably important quantities in Patagonia, or Labrador, or the frozen wastes that Peary traversed and Cook didn't traverse en route to the Pole, half the world would go diamond mad; and men would pawn their watches or mortgage their farms in order

Washing Plant.

to try their luck in a gamble of such tremendous possibilities. Yet gem experts of acknowledged ability and integrity are responsible for the statement that the surface finds in the Arkansas diamond fields exceed anything that was discovered in the South African mines at a corresponding period in their exploitation; that the diamonds recovered

Testing Plant.

fully equal those of the De Beers Consolidated mines in average value per carat; that the haphazard washing operations so far performed have yielded greater returns from the amount of material handled than some of the great mines of Africa give; and that the diamond-bearing formation may reasonably be expected to extend so far into the earth that operations will be limited only by engineering and economic considerations; and no great stampede has taken place. The discovery of diamonds in Arkansas was announced more than three years ago, and officially confirmed in publications of the United States Geological Survey. It caused no excitement, excepting among the farmers of the immediate neighborhood; and has aroused less comment than the commonplace announcement of another Pittsburg divorce scandal. Perhaps this cold-blooded reception of news that ought to have created a sensation was due to a deep-seated conviction that nothing good could come out of Arkansas. Or perhaps the American people have been educated to believe that it is only far-away birds that have fine feathers, and that if diamonds existed so close to trolley cars and civilization they would have been adorning the short-fronts of our captains of industry, head waiters, and green-goods artists long ere this.

In 1906 John M. Huddleston bought a tract of land in Pike county, Arkansas, two and a half miles from Murfreesboro, and 120 miles from Little Rock. In places the soil presented a peculiar appearance, being stained in curious hues of green and blue, leading Mr. Huddleston to suspect that copper, lead, or other valuable minerals or metals might be found in the neighborhood. On the first day of August, as he was down on his hands and knees looking for indications of these, he picked up small crystal, which he suspected might be a diamond, although he was not sure. That afternoon he started to ride into Murfreesboro, when he saw a second crystal lying in a rut by the roadside. He dismounted and secured this also. The crystals he showed to a jeweler in Little Rock, who pronounced them genuine diamonds, the first one weighing four and a half carats, and the other weighing three

Peridotite Area, Arkansas Diamond Field.

carats. Mr. Huddleston and his family immediately began a still hunt for diamonds, examining the ground where the first stones had been found with minute care. No more stones were found until September 8, when another was picked up. Then people in Little Rock began to take notice, and Sam W. Reyburn, Charles S. Stifft, and Albert D. Cohn started an investigation on their own account. They found that the region in which the Huddleston farm was situated had been described as a volcanic area as long ago as in 1842, by W. B. Powell; and that J. C. Branner and R. N. Brackett, of the Arkansas

Geological Survey, had commented upon the lands in 1890 as consisting of decomposed peridotite and possibly diamond bearing. That the diamonds of South Africa occur in peridotite is well known. The men mentioned secured an option on the Huddleston farm, and went to New Yok City to consult with George F. Kunz, America's most famous gem expert.

Mr. Kunz pronounced the stones shown him to be diamonds beyond the shadow of a doubt, and recommended that Henry S. Washington be employed, if possible, to examine the locality, determine whether the diamonds were found in the original rock formation, and report upon the probable extent of the diamond-bearing area. Mr. Washington made a careful and exhaustive examination of the locality, and later Mr. Kunz visited the ground and spent some time there for the same purpose. Soon afterward John T. Fuller, for five years connected with the De Beers Consolidated mines, first in the capacity of mining engineer and later as mine manager, visited Pike county, with the same object. Messrs. Kunz and Washington read a paper on 'Diamonds in Arkansas' at the New York meeting of the American Institute of Mining Engineers, February 1908, and also supplied one on the 'Occurrence of Diamonds in Arkansas' for publication by the United States Geological Survey in 'Mineral Resources of the United States for 1906.' In the latter they stated that the "occurrence of diamonds in the peridotite of Murfreesboro may be regarded as unquestionable:" that "most of the stones are white, a large proportion being of good water and the white of exceptional purity, finer than most African stones;" and that "this is the only place outside of South Africa where diamonds have been found in peridotite." This official recognition places the Arkansas diamond mines safely beyond suspicion.

Whether the diamonds are abundant enough to justify extensive mining operations and a costly washing plant remains to be seen. This point can be settled definitely and beyond doubt or question only by the expenditure of time, capital, and labor necessary to find out. Upon this phase of the subject the judgment of a practical mining engineer, whose experience was gained in the world's greatest diamond mines ought to be of some value. It is this consideration that makes Mr. Fuller's report interesting and important. He states that the peridotite in which the Murfreesboro diamonds are found occurs in a true volcanic 'pipe', similar to those of South Africa: that this 'pipe' will extend vertically for an unknown depth into the earth, so that mining operations will be limited in depth only by economic and engineering considerations, and not at all by a failure in continuity of the deposit; that the known diamond-bearing area is approximately 60 acres in extent: and that the indications from the slight operations so far carried on point to an average yield of 0.21 carat per truckload of 16 cubic feet excavated from the pipe. As the great Jagersfontein mine of the Kimberley district averages only 0.13 carat per truck-load, and others of the South African mines fall below the estimate made for the Arkansas mines, Mr. Fuller's report may fairly be considered equivalent to a prediction that Murfreesboro is destined to become one of the world's great gem mining centres. The Roberts-Victor mine, discovered in 1905, and considered one of the coming mines of the Transvaal, yields 0.70 carat per load of 16 cubic feet. The owners of the Arkansas diamond mine (the Murfreesboro property upon which the greatest amount of development work has been done) believe that their property will do as well.

Following the public announcement of Mr. Huddleston's discovery of real diamonds, the farmers of Pike county began a frenzied search for similar crystals upon their own lands; and people might be seen in every field and along every fence-row, down on hands and knees searching in the dirt and gravel for gems. The ordinary labors of the farms were neglected—for who would dig potatoes or hoe corn when diamonds might be picked from the surface? Altogether more than a thousand gems have been found so far, most of these coming from the Huddleston and adjoining properties. Numerous diamond-mining companies have been organized, and some of these are selling stock and making extravagant claims for properties far away from the volcanic pipe, where the presence of diamonds (unless carried there) would be a mineralogical miracle. Some of these diamond-mining companies are making preparations to work the deposits in a thorough and systematic manner, in the confident expectation of building up in Arkansas a great, permanent, and profitable gem mining industry. Others evidently have no other object in view than to 'work' the public, and sink the proceeds of sales of stock deep into the pockets of the promoters, rather than into shafts and drill-holes.

Thus it appears that the long-sought American diamond field has been found. Its extent and value are yet wholly problematical, but indications point to the existence of an important deposit of the most desired of all gems. The geology of the region is so well known that the discovery of more than one pipe of volcanic blue ground is hardly to be hoped for, though the extent of the original pipe is not known and kimberlite is reported to have been found under cover more than a half mile to the east. Probably the Arkansas diamond fields will never rival those of South Africa in extent. Nevertheless it is not impossible that the single pipe that has been discovered will prove as rich as any similar one in South Africa. No large stones have yet been found in Arkansas. The largest so far recovered weighed six and a half carats, and the average weight of the first fifty stones found was about half a carat. Of course, the larger the stone the greater the value per carat; but a compensating circumstance is found in the fact that the market for small stones is constant and practically unlimited, while the demand for large stones is uncertain and variable. During the recent financial depression, the De Beers, Dutoitspan, and Jagersfontein mines, which produce mostly small stones, operated continuously, while the Premier, and other mines that produce many stones of large size, closed down on account of great accumulations of unsold gems.

Theory of the Dissolution of Metals by Cyanide

By J. B. Stuart

Not long ago the tendency of those cyaniding silver ores was to rely upon a maximum degree of dilution to accomplish the maximum extraction, believing that the rate at which the silver went into solution was accelerated thereby. Hence they tried to use as many tons of barren solution per ton of slime as possible. Later this idea gave way to better practice, and the primary reason for the large bulk of solution required was found to be merely the need of washing the dissolved metals from the charge. With the perfection of filter plants, as against decantation plants, it became apparent that washing of dissolved gold and silver by dilution was by no means as perfect in the agitation and decantation method as in its displacement by the filtration methods of washing. Then it was appreciated to what extent mechanical-agitation methods suffered, from revolution *en masse* of solution and solids. In the case of filter methods of washing, there could be no doubt that the barren solution, or water, actually displaced the metal-bearing solution, retained as moisture in the cake. On the other hand, a quantity of barren solution, or water, several times as great as that used in filter methods, failed to accomplish anything like so satisfactory a 'wash' when applied by mechanical-agitation methods. This, I take it, points very clearly to the need of maintaining as high a difference between the relative velocities of slime particles and solution as possible; and the primary object of such methods I consider is to promote the diffusion of the dissolved metal from the immediate surface of the slime particles to the general mass of solution involved in the charges.

TABLE OF SURFACE AREA OF PARTICLES

Screen No.	Screen coef.	Per cent max. surface exp.	Sq. m. sur. per 1 m. ton sp. gr. 25	Sq. m. sur. per cu. m.
10	1	3.03	960	2400
20	4	6.06	1920	4800
30	9	9.09	2880	7200
40	16	12.12	3840	9600
50	25	15.15	4800	12000
60	36	18.18	5760	14400
80	64	24.24	7680	19200
100	100	30.30	9600	24000
110	121	33.33	10560	26400
120	144	36.36	11520	28800
130	169	39.39	12480	31200
140	196	42.42	13440	33600
150	225	45.45	14400	36000
160	256	48.48	15360	38400
170	289	51.51	16320	40800
180	324	54.54	17280	43200
190	361	57.57	18240	45600
200	400	60.60	19200	48000
250	625	75.75	24000	60000
300	900	90.90	28800	72000
330	1000	100.00	31680	79200

To illustrate the increased efficiency obtained in treatment by moving the solution relatively faster or slower than the slime particles, the following comparison was made of treatment by the Brown or Pachuca tank method and that of mechanically-rotated paddle-agitation assisted by vanes on sides of the tank and one 4-in. air-lift at one side. To make the comparison a little more satisfactory, the screen tests on the charge were reduced to a single figure representing the mesh number of a uniform material which would present the same surface per ton for contact with solution, as that indicated by the screen tests. Perhaps others may like to use the same method, so I will further explain it. For purposes of comparison only, and to eliminate difficulties due to irregularities in size of wire and air spaces, I speak of '10-mesh' as cubes of 1/10-in. on a side and '100-mesh' as cubes of 1/100-in. on a side. Under these conditions, then, material of 2.5 sp. gr. would present the surface as indicated in the table above.

If, now, in any screen test the percentage remaining on each screen is multiplied by the corresponding percentage area for that size, and the percentage passing 200 mesh be considered as all remaining on 250 mesh and multiplied accordingly, this will determine the average screen size. The sum of all these products gives the total surface exposed for contact with solution. Take the following example:

On 10-mesh	1% × 3.03 =	0.0303%	of total area.
40 "	4% × 12.12 =	0.4848%	"
80 "	8% × 24.24 =	1.9390%	"
100 "	10% × 30.30 =	3.0300%	"
150 "	15% × 45.45 =	6.8170%	"
200 "	20% × 60.60 =	12.1200%	"
250 "	42% × 75.75 =	31.8000%	"
		56.2211%	

From this it may be concluded that the screen tests indicate material of average size a trifle coarser than 190 mesh exposes 56.22% of the maximum surface possible. Although not strictly correct, still, when dealing always with the same ore, it may be said 56% of the gold and silver content of the ore would be exposed by such size material for complete extraction.

In my Pachuca-tank test, the charge showed material equivalent to 146 mesh, assaying 237 gm. Ag per metric ton, in a dilution of 1 to 1½, yielding 77% extraction in 36 hours agitation. This implies 44.24% (14.6 by 3.03) of the total surface was exposed or 104.84 gm. Ag per ton were readily accessible to the solution. In the mechanically-rotated paddle-agitation assisted by one 4-in. air-lift, the charge showed material equivalent to 187 mesh, assaying 397 gm. per metric ton, in a dilution of 1:35, yielding 70% extraction in 33 hours agitation. The surface exposed was 56.66% (18.7 by 3.03) of the total possible, and 224.7 gm. Ag per ton were readily accessible for dissolution.

I claim that in the Pachuca-tank treatment 32.76% (77%—44.24) of the content was extracted from imperfectly exposed Ag; and that by the other treatment only 13.34% (70—56.66) of the content was extracted from imperfectly exposed material.

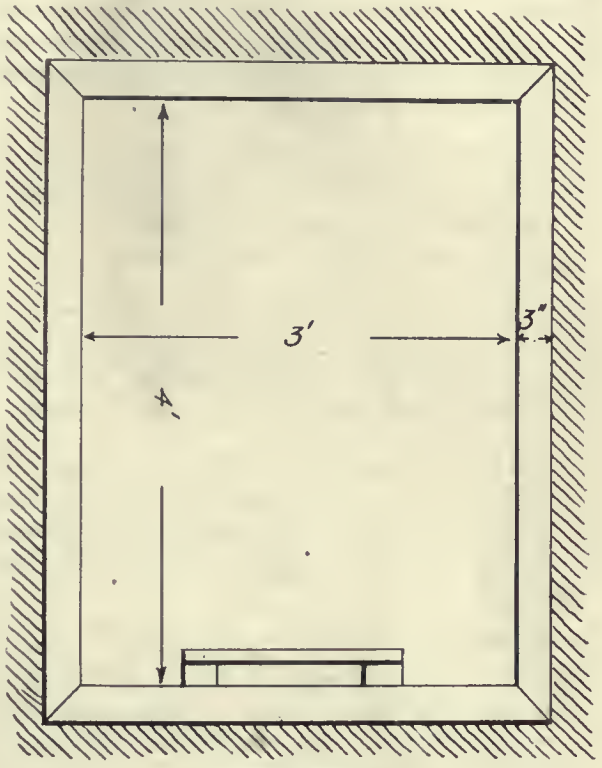
Inasmuch as the two charges did not assay the same, further investigation is desirable. In the first

case, to get 77% of 237 gm., 182.49 had to be dissolved, and of this, 104.8 were free—hence, 77.7 gm. was dissolved from imperfectly exposed material assaying 132.2 gm. per ton (237—104.8), making the extraction of this material only, 58.8%. Applying the same methods to the mechanical-agitation experiment, it is found 277.9 gm. had to be dissolved out of 397 present to get 70%, of which 224.7 gm. was free, leaving —53.2 gm. (277.9—224.7) to be dissolved from a total of 172.3 gm. of imperfectly exposed Ag, which corresponds to an efficiency of 30.7% on this imperfectly exposed silver. It is obviously easier to obtain any given percentage extraction upon a high-grade ore than on a low-grade ore, so the limit to which tailing-value may be reduced in a given time is of more importance than the mere percentage extraction obtained. Thus it becomes clear that the extraction by the air-lift tanks is far more satisfactory than that made in rotary paddle agitation. The latest advance in this direction is the Just process in which the charge is practically only kept in a distended condition with just enough disturbance to cause diffusion of the enriched solution from the surfaces of the slime particles to the general mass of solution occupying the interstitial space. The advantages offered by the Just process over the Pachuca-tank treatment are many, and obvious to all engaged in operation of cyanide plants. Its universal adoption is only dependent upon further proof that the silica-sponge false-bottom will not gradually become choked. Under normal conditions, it appears to be free from this danger, as only air is passing through it and no lime-water gets to the pores. But how about the effect of frequent shut-downs for lack of power so common in many camps? When the blower stops, the charge begins to settle and the slime and lime-bearing solution are bound to find their way into the porous tiles to a considerable degree. With the pressure of a well settled slime charge it would be strange if the pores of the tile did not become more or less clogged and the hydraulic lime, so universal in Mexico, is likely to make a pretty firm deposit in a short time. After such a shut-down, it is possible that the extra air-pressure necessary to break through the densely packed sandy slime of a reground product may occasionally break a tile. Or it may be that the pressure required to break up the charge will be greater than that obtainable from the blower used. This would be a great disadvantage indeed, if compressed air had to be used from time to time, as it is one of the strong points in favor of the Just process that it operates perfectly with a blower, instead of a compressor. The moderate volume of air used in ordinary practice must, no doubt, be a great factor in reducing cyanide consumption to a minimum.

The Illinois Geological Survey has prepared a map of the Sandoval oilfield, which shows an extensive dome within the —200-ft contour, measured from the No. 6 coal. The oil already found lies within or near the —125-ft. contour, but the remaining area is thought to be prospective value. It is further believed that the dome is not isolated.

LINING FOR MANWAY THROUGH WASTE

The accompanying sketch shows a simple method of lining a manway through broken ore or waste, adapted to high rock-filled stopes in Los Pilares mine, Naeozari, Mexico. No framed timbers are employed. Planking 3 by 12 in. are fitted snugly with bevel joints at the corners. The pressure of the set-



Details of Manway.

tling mass of broken rock holds the lining firmly in place. Considerable care is required in stowing the rock around the boards as the manway is carried above the level of the filling. The ladder strips are spiked to the planking, and no difficulty is experienced in maintaining alignment. In fact the ladders assist in stiffening the lining.

NEW TOPOGRAPHIC MAPS

The topographic maps named below were issued by the United States Geological Survey during the months of April, May, and June, 1910:

Antietam, Md.-Va.-W. Va.
Bedford, Pa.
*Bisbee, Ariz.
Bloomington, Ind.
Breckenridge Special, Colo.
*Burnet, Texas.

The United States relief map sells for 10c., the Yosemite National Park administrative map sells for 25c.; the other sheets mentioned for 5c. each.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A shoveler who fills 15 ordinary mine-cars on a shift is doing good work. Many of them fail to accomplish as much as this.

Failure of the steam or air safety valve to blow off promptly when the steam gauge indicates the pressure at which the valve should release, calls for prompt examination into the cause.

A fall of 8 in. to the 12-ft. box is the usual grade of placer sluices. Some material requires a heavier fall than this, and it may be necessary to give the boxes more slant owing to scarcity of water.

Safety valves on boilers should be frequently tested, as they often become rusty and are then likely to stick on the seat. The outlet of each safety valve should be the full size of the valve opening.

California is notably a gold-mining State, but there are no very large stamp-mills in the State. The largest contains but 120 stamps, and there are few of 100. The usual number under a single roof is 40 or 60.

A switch should always be placed between the motor and the transformers where machinery is driven by electricity, as this will save much time and insure safety in case of burning out fuses or accident to the motor itself.

Steam and compressed air may be employed together in the cylinder of a steam engine to advantage if it is convenient to do so, and contrary to expectation the condensation of steam under such conditions is much less than is generally supposed.

Amalgam may be removed from plates with an ordinary glazier's knife. Indeed, there is no better utensil with which to do the work. The knife is far superior to the hoe-shaped and straight-edged chisels generally made from old files, and used for this purpose. The putty knife has the advantage of elasticity, which the file chisel lacks, to its detriment.

The South Pass district, Wyoming, is in the south central part of Fremont county, in the central portion of the State, and at the south end of the Wind River range of mountains. Gold was discovered in this district in 1842, but it was not until 1870 that actual mining of consequence was done. In that year the placers that would pay were practically worked out, and a number of quartz veins discovered.

Platinum prices are very unstable, varying between $18 and $30 per ounce. Figures given by the United States Geological Survey vary between $4 and $7 per ounce for the crude material between the years 1880 and 1900. From the latter date to the present the price for the refined metal has ranged from $20 to $30 per ounce, the lowest year being 1905, with an average of $16.75, and the highest 1906, when the average price was $30.70.

Cinnabar is a sulphide of mercury, HgS, and when pure contains 86.2% of mercury. It is very heavy, its specific gravity being 8 to 8.2; it occurs in bright vermillion to brownish-red masses of granular texture; more rarely as small transparent rhombohedral crystals, as a bright scarlet powder, or as an earthy red mass. Easy tests are: heat the powder in a closed tube when a sublimate of mercury, or a 'mirror,' will form in the cooler part of the tube, or if cinnabar powder is moistened with hydrochloric acid and rubbed on a bright copper, the coin will be coated with mercury.

The deepest vertical shaft in America at any gold mine is the Kennedy, at Jackson, California, which is 3450 feet. There are deeper shafts in gold mines at Bendigo, Australia, and on the Rand, South Africa. The deepest vertical shaft in the world at present is the Tamarack No. 3, near Houghton, Michigan. It is 5253 ft. deep, lacking 27 ft. of being a mile. No. 5 shaft of the Tamarack company is 5089 ft. deep. The deepest shaft of the Calumet & Hecla mine, adjoining the Tamarack, is the Red Jacket, 4920 ft. deep. For a long time this was the deepest shaft in the world, but has been superseded in this by the Tamarack shafts.

Danger is always present when high-pressure boilers are used unless they are given frequent and proper inspection. At the beginning and end of each watch the man on shift should ascertain if the valves between the boiler and water column, as indicated in the gauge glass, are open. Open the lower cock and close again noting the return of water to the glass. Test the gauge-cocks thoroughly until absolutely sure of the water-level in the boiler. Open the door to the boiler end daily and examine carefully every inch of surface exposed for leaks, particularly the tube ends, seams, and blow-off pipe. If any leaks are discovered they should be repaired without delay.

Tantalum is used in steel making, but the utility of tantalum-steel alloys is as yet undetermined; at least its metallurgy may be said still to be in the experimental stage. Iron alloyed with 5 to 10% tantalum is hard, but is ductile. Scientific investigators have experimented with a number of tantalum-steel alloys, but have thus far found them of no commercial value. It is thought that possibly had the steel contained a higher percentage of carbon more satisfactory results might have been obtained. Tantalum has the strange property of transforming an alternating into a direct current. With 120 volts or less, two electrodes of tantalum dipped into a bath of dilute sulphuric acid will completely stop an alternating electric current, but if one of the tantalum electrodes be replaced by one of platinum, the current will continue to flow, but in one direction only. The uses for tantalum are increasing and in time it may occupy a much more important place in metallurgy than at present.

Special Correspondence

JOHANNESBURG, TRANSVAAL

Another Power Scheme.— Vogelstein's Consolidated Deep.

The electrification of Transvaal industries is one of the most discussed topics in South Africa at present. The passing of the Power Bill and the advancement of construction work at the Victoria Falls Power Co.'s plants, at Germiston, have quickened interest in the subject, and now the flotation of another huge undertaking, which will supply power throughout the Pretoria and Middelburg districts, has rendered the matter more vital than ever. The opposition of 'back-veld' Boer to anything in the nature of industrial advancement, appears to be breaking down, and in the face of the manifest advantages that will accrue to the country through the employment of electrical power, generated from large central stations, and the progressive and sympathetic attitude adopted by the leaders of the Dutch in Parliament, it is not to be wondered at that ignorant prejudice is waning. The new power project referred to above is popularly termed 'The Tweefontein Power scheme,' but it is understood that the power venture has for the time being, the title of the Transvaal Hydraulic Syndicate. Application has been made for a license, under act No. 15 of 1910 of the Transvaal, to erect and install machinery and plant, and to carry on and engage in an undertaking for the supply of power from a generating station, to be erected upon the farm Tweefontein No. 236, in the Middelburg district. It is proposed to form a company with a nominal capital of £926,000 (cash working capital £842,000), vendors £84,000, for the purpose of taking over and operating the undertaking. An area of 20 acres will be purchased by the Power Syndicate, from the Tweefontein Colliery, Ltd., the Syndicate contracting to purchase from the Colliery, a minimum of 25,000 tons per month of small coal, pickings, and second-class coal, over a long period of years, at an agreed and satisfactory price to both parties. The business may be regarded as favorable to both the Colliery owners and the Power Syndicate. The former will be able to dispose of all fines and pickings, the great majority of which at present represents waste product, while the generating station will be actually on the site of a colliery, and use will be made of the cheapest possible material in the production of electricity. The estimated cost of generation on a basis of 36,000-kw. years is as follows:

Coal, 450,000 tons, at 4s. per ton..	£ 90,000
Salaries and wages	24,105
Depreciation and maintenance...	20,000
Interest and amortization.....	83,340
Oil and stores.....	7,750
Water	5,000
Total	£230,195

This is equal to £6 7s. 10d. per kw.-year, or 175d. per kw.-hour. The minimum amount of power it is intended to sell to any one customer is 45,000 kw.-hours per annum. It is proposed by the promoters of the project to supply power to all classes of consumers (mining, municipal, industrial, and agricultural), within the Pretoria, Middelburg, and Witbank areas. Among the concerns mentioned in this connection, are the Premier Diamond mine, South African railways and workshops, Middelburg and Witbank collieries, Modderfontein dynamite factory, a proposed electro-chemical works at Tweefontein, the military cantonments, Roberts Heights, and the Olifantsfontein pottery works. The scheme is evidently most comprehensive and ambitious, and in conjunction with the Victoria Falls Power Co.'s stations on the Rand, it should do much for industry in Central South Africa.

No other property on the Witwatersrand has occasioned so much disappointment of recent years as the Vogelstein's Consolidated Deep, a mine situated near Florida, and controlled by the firm of S. Neumann & Co. The company started milling in January of this year, and for the first five months of 1910, has recorded a total loss of £8592. The Vogelstein Deep has in fact been the 'bad egg' of the Witwatersrand, and the disappointing grade of ore recovered, coupled with the high rate of working expenditure, have had a depressing effect on the Kaffir market. Some idea of the extent of the losses incurred in this enterprise may be gathered from the facts, that early last year the shares were quoted at 47s. 6d., whereas today they stand at only 6s. The company has had a most chequered career, has been reconstructed three or four times, and is today saddled with liabilities amounting to over £130,000. Two days ago a circular was issued to shareholders, inviting them to subscribe for £210,000, six per cent, first-mortgage debentures at 90%. The circular states that in the event of the issue being insufficiently subscribed, the directors will be reluctantly compelled to close down the mine. The sum of money asked for, if provided, will be applied to development and the enlarging of the crushing plant from 10,000 to 15,000 tons capacity per month. The poor results so far obtained are ascribed to the presence of a bad hanging wall, which has resulted in an abnormally large stoping width, and therefore a low grade of ore, and also because of high-working costs due to inability to supply the mill at full capacity. The payable ore reserves are now estimated to be on South Reef, 170,000 tons, assaying 5¾ dwt., 37 in. wide; on Main Reef, 15,000 tons, assaying 5 dwt., 78 in. wide. The directors state that the milling of these reserves should yield profits, provided the plant were supplied to full capacity which, owing to the limited number of stope-faces available, is not, however, possible. Clearly, a vigorous policy of development and production on a larger basis is the only alternative to closing down the mine. Why the directors should deem 15,000 tons a month a sufficiently large stamping basis, is difficult to understand. On such a scale of operations, the profit can scarcely be anything of much consequence. The mine is clearly a low-grade property, and now that it is imperative to reorganize the policy of the Vogelstein Deep, it would probably be better for all concerned to once and for all develop and equip the venture on a basis commensurate with its low-grade possibilities. The expenditure of £210,000 can hardly be expected to achieve this.

LONDON

Fume Question in Cornwall.—Safety in Cornish Mining.—Mexican Mines in London. —Mond Nickel. — Waihi Grand Junction.—Great Fitzroy Difficulties.

The revival of activity at the Wheal Jane mine, in Cornwall, has caused difficulties with neighboring farmers, for the company is roasting the tin concentrate for the purpose of decomposing the iron pyrite preliminary to a second concentration. The pyrite contains a good deal of arsenic also, though apparently not sufficient to make it worth saving. The roasting is done at the old Carnon Chemical Works, in the Bissoe valley. The Redruth council has taken the matter up, and Alfred C. Fryer, the inspector under the Alkali Act, has visited the works. Some modifications have been made in the process, though up to the present time, no official action has been taken. The South Crofty company, at Camborne, has also received much opposition by the local farmers, owing to the fumes from the roasting and arsenic furnaces. Here the arsenic is a valuable by-product. The company has spent money on additional settling flues and on higher chimneys. An action against it will come on in the courts at the end of July, and the exact facts of the case will then be made public.

The Royal Commission on Safety in Metalliferous Mines has already held several sittings, and some most interesting evidence has been given by J. S. Martin, who recently retired from the position of inspector of the southern district, which includes Cornwall. As regards the safety of working in Cornish mines, he frankly admitted that conditions were far from ideal, but he saw little chance of their being improved in any important way. The mines

are not blessed with much capital, or with rich ore-shoots. He said that if sufficient capital was assured, and if philanthropy was the paramount consideration, he would advise the sinking of new shafts on modern lines, and levels on the same generous scale. There are, indeed, few shafts in Cornwall to which an engineer can point with pride. Dolcoath has spent £60,000 in sinking a new shaft, and more will be required for its equipment. This work has been going on for years, and connection with the old shaft has only recently been made. The ventilation has thereby been improved, but no hauling or pumping has yet been done by the new shaft. The worst of it is that the new shaft is circular, and brick-lined, though it goes through hard granite. The consulting engineers who recommended this form were identified solely with coal mining, which, owing to the softness and wateriness of the overlying strata, demands this shape of shaft. Therefore, in quoting examples of modern practice in mining, we usually conveniently forget the new shaft at Dolcoath. The new shaft and cross-cuts at South Crofty, would undoubtedly pass Mr. Martin's ideal requirements, and so would the work at Wheal Kitty, which, though on a much smaller scale, is a pattern of modern economic methods. With these exceptions, Mr. Martin's structures and reflections are only too well deserved.

Another Mexican gold and silver property is to be introduced in London. This has been acquired by the Asso-

Zacatecas, Mexico.

ciated Northern Blocks, one of the Landau mines at Kalgoorlie, which is arriving at a period when exhaustion has to be seriously considered. W. E. Simpson has been in Mexico for some time, looking for mines, and that which he has recommended is in Zacatecas, close to the Benito Juarez. It is an old mine and the ore is amenable to the modern cyanide process.

The Mond Nickel company was formed ten years ago to acquire nickel-copper mines at Sudbury, Ontario, and to refine the matte at Clydach, Swansea, by the late Ludwig Mond's process, according to which the nickel is removed as a volatile carbonyl compound, while the copper is subsequently obtained as sulphate. At first the refining process gave much trouble; it is intricate as well as dangerous. During the first three years the inventor, who had originally taken his purchase consideration in ordinary and deferred shares, decided to pay the dividends on the preferred shares out of his own pocket, as the process had taken much longer to perfect than he had contemplated. The issued capital of the company is £400,000 in preferred shares, carrying a cumulative dividend of 7%, £300,000 in ordinary shares, and £50,000 in deferred shares. During the year ended April 30, 1904, the company earned sufficient profit to pay the preference dividend; the year after saw a dividend of 6% on the ordinary shares; and for the year 1905-6 the deferred shares received 18%. The ordinary dividend was 10% in 1905-6, 12% in 1906-7, and 15% regularly since. The dividend on the deferred shares rose to 33% in 1906-7, and has been 48% since. The report for the year ended April 30, last, shows a net profit of £114,106, figures which are almost identical with those of the two previous years. The company does not give any figures relating to the production of copper sulphate or nickel, but states that operations have been extended, thus making it possible to maintain profits in spite of the low price of copper. The consumption of nickel is increasing, especially for use in making nickel steel for bridge building and other structural work. The report also records that the hydro-electric plant, on the Vermilion river, is completed, and is supplying power to the mine and smelter. This plant is owned and operated by a subsidiary local company in order to comply with Canadian charter. Some current is sold to outside customers, and additional profits will accrue to the nickel company. The directors refer with regret to the decease of Ludwig Mond, by whose unremitting application, the company was brought to a success. We should like here also to record the valuable services given to the company and Mr. Mond by Carl Langer, the metallurgical engineer at Clydach.

The Waihi Grand Junction company was formed in 1895, to acquire property to the west of the Waihi gold mine. Three of the Waihi lodes are found in the Grand Junction mine, namely, the Martha, Royal, and Empire. For many years prospecting and development gave disappointing results, and large amounts of capital have been expended. Milling eventually commenced in 1906, with 40 stamps bought from the Kauri company, and 4 tube-mills and cyanide plant were added. More recently 60 new and heavier stamps, and 6 tube-mills were purchased, but have not yet been erected. F. C. Brown, known in connection with agitator-vats and tube-mill lining, was, until the end of 1909, the general manager, when he was succeeded by W. F. Grace, who had shortly before been sent out to examine, on behalf of people who had provided further funds for working capital. The report for 1909 was published last month, but by far the most interesting and important information relates to the period since the close of the year, for the underground development, conducted under Mr. Grace's directions, have been both energetic and successful. At the meeting of shareholders, the recent discoveries were given in detail, from which it would appear that the Royal lode promises to become an important producer. The Empire lode is developing in a satisfactory way, and a new lode, christened the George, has been found. The yield has been continually improving and the costs decreasing, so that the results during the first five months of this year are an improvement on those of a year ago. As regards the results for 1909, it is reported that the general conditions improved greatly as the year went on, so that a profit was made in spite of the gloomy results published in the half-yearly report issued during the summer. The mill treated 59,147 short tons, yielding bullion worth £100,687 or 39s. 5d. per ton. Mining cost £37,045, extraction £24,489, development redemption £11,829, administration in New Zealand £6306, in London £3256, depreciation £7279, gold duty and realization expenses £4220; there were other small items, and the balance of profit was £5729. This result is encouraging, after so many years' expenditure and debits. For the first five months of 1909, the ore treated was 28,952 tons, and the yield was worth £44,822. Mr. Grace does not propose at present to erect the 60 new stamps, but has added two of the tube-mills to the plant, and finds that the installation can treat 400 tons per day. He has also improved the extraction, by installing a system for keeping the circulating cyanide solutions clean. No mercury is used in the stamps, and the ore is 'all-slimed'; recently the extraction fell away and Mr. Grace examined the cyanide circuit and detected the weak point. By means of the improvements introduced, the extraction is improved and the consumption of cyanide decreased. During the past year the capital was increased by the issue of 70,000 new shares, which were taken by shareholders at par, with rights to subscribe to 35,000 other shares at 30s. each; by this means the debt of £60,000, raised by loan, has been discharged, and an ample supply of working capital provided.

For some time the shares of the Great Fitzroy copper mine at Mount Chalmers, Queensland, have been depressed,

much to the mystification of the shareholders and public, who had previously been impressed by the excellent reports of great bodies of copper ore. That something was wrong was evident, though no statement was published. A note has now been issued by Bewick, Moreing & Co., the managers, announcing that W. J. Loring has advised an alteration in the plans. It appears that water concentration has been unsatisfactory, and that the results expected, and indeed claimed by the superintendent, have not been obtained. Accordingly, the concentration mill has been closed, and all efforts are being centred on pushing forward the construction of the flotation plant and sintering furnaces. In the meantime only one smelting furnace is in operation, working on crude ore. The company announces that the flotation process, owned by the Minerals Separation, Ltd., is to be adopted. This process is the invention of Sulman, Picard, and Ballot, and has been in operation for some years at the Sulphide Corporation's mine, at Broken Hill. Three years ago it was tried by the Zinc Corporation, at the same centre, but it did not give good results there. Since then the mechanical details have been worked out by Theodore J. Hoover, whose practical and theoretical skill as an engineer, has been of the greatest possible value. Some of the shareholders of Great Fitzroy have been grumbling about the adoption of this process, and point to its failure at the Zinc Corporation, but they ought to know that the process has advanced a long way since those days. They also object, because the litigation is still going on, in Australia, between the Minerals Separation and the Elmores. My point of view is that its adoption in this case may bring about the long desired pacification of the rival flotation patentees, either by an amalgamation of interests or by a mutual agreement to 'cease firing.'

KALGOORLIE, WESTERN AUSTRALIA

Diamond-Drill Results in Kalgurli.— Chamber of Mines. — Government Work.—Water Supply.—Perseverance Installation.

During May the gold mines in the State produced gold valued at $2,715,000, and paid dividends totaling $63,500. The principal mines returned the following:

Name.	Tonnage.	Yield.	Profit.	Dividend.
Associated	12,004	$73,000	$750†	.....
Asso. Northern Blocks	2,036	15,000	5,500	.....
Chaffers	4,340	31,000	1,100	.....

*From residue treatment. †Loss. ‡April.

At 1550 ft. in the Kalgurli, the diamond-drill cut 58 ft. of ore, worth $25 per ton, 19 ft. of this being high grade, and in a week or two the cross-cut will have intersected the lode. The Kalgurli has always been noted for its wide lodes, which are of no great length, but persist in depth. Acting on the advice of Malcolm Maclaren, geologist for the Ivanhoe, the company has started drilling west from 2000-ft. depth, in one of the Horseshoe shafts, known as the Ivanhoe South Extended. It is argued that there may be a parallel series of lodes to those in the Ivanhoe and Horseshoe on this side. The old Ivanhoe Junction, recently bought by the Ivanhoe, worked a lode west of the latter, but results were not payable, although work was only carried on in a half-hearted manner, with a wretched plant. It is to be hoped that this drilling will prove an extension of the Golden Mile laterally.

The Chamber of Mines, after much consideration, has made suggestions to the Minister of Mines, that the Government should send out geologists to examine the country between known fields, and so connect them, and issue reports which would be of value to prospectors and others, such as is done in the United States and elsewhere. Also, that parties of prospectors should be sent out searching for new fields. The Chamber pointed out that Western Australia had very little spent on it geologically, when compared with other countries. The Minister is in favor of the first proposal; but would not promise anything in connection with the latter just yet. Parties have been aided from time to time, but results have not been satisfactory. The expense of the geological surveys asked for will not cost more than $25,000 in two years, a trifling sum to aid a decreasing industry, that in less than twenty years has produced about $475,000,000; paying $15,000,000 in wages, besides other large amounts for stores, and which supplies two-thirds of the value of all exports from the State.

Word comes by telegram from the boring party at work on the Trans-Australian railroad, that a good supply of fresh water had been cut at depth of 1290 ft., not far from the Great Australian Bight. This is of great importance to the proposed line; as the sum of $3,000,000 is set down for the cost of a water-supply. Mr. Maitland, geologist of the Government Survey, has always been of the opinion that there is a basin in this district. The commission on phthisis among miners is still taking evidence and examining certain cases. There have been many cases of bronchitis, but few were associated with fibrosis in the Murchison field. Men who had a cough, took a fortnight's rest and recovered; but when they returned to work it reappeared. This was only bronchitis, and not tuberculosis. It may be remembered that the Government sued the Golden Horseshoe for some $21,000, for dividend duty not paid, and the company lost the case. It then went to the Full Court, which upheld the decision, so now a final appeal is to be made to the Privy Council. If the company loses before this tribunal, the dividend-paying mines will have to pay up over $150,000.

During the month the Kalgoorlie mines consumed 34,472,000 gal. of water. The corrosion of the main conduit is causing much investigation, and it is proposed to erect a station near the reservoir, 353 miles away, to add 5 grains of CaO per gallon to prevent this; also, to erect suitable regulating tanks which would relieve the pumps of some of their work. The English experts consulted, reckoned that air should be prevented from entering the main, but the efficacy of this is doubtful and the cost high. Mr. Mann, Inspector of Explosives, argues that oxygen is not the cause of corrosion, but hydrogen. The water is very corrosive in the main pipes, but it does not affect boilers on the mines, although where hot water is in circulation in the mills the pipes last under 12 months. It would seem that wood pipes would solve the difficulty, after the steel main has had its day, although 353 miles of 25 to 30-in. wood pipe is a big order.

The Associated has just erected two No. 8 Krupp ball-mills, and these would operate to perfection as dry crushing machines. They cost some $4000 each, and running at 21 r.p.m., loaded with 4400 lb. of steel balls, and crushing a hard ore through a 30-mesh screen, at the rate of 92 tons each per day, consume only 50 hp., with milling costs 50c. per ton. The No. 5 size is very useful in a small plant, and crushes about 43 tons per day through 25 mesh. At the Ivanhoe experiments have been made on the residue dump by the vacuum process; but results are not public yet. The engineer on the mine has invented another type of slime-filter. To relieve the hoist at the main shaft, a Fraser & Chalmers single drum, Corliss gear hoist is just about ready for work in the third compartment of this shaft. The Great Boulder and Horseshoe have hoists on their third compartments also, as well as working other

shafts. Twenty head of new stamps have been erected at the old mill at the Horseshoe, and remodeling of the other 50 is in progress. At the new mill of 100 head, extra tube-mills are being installed.

All is bustle at the Perseverance; the main hoist is being overhauled; one 30-drill Walker compressor is complete, while the second one has just arrived; the ball-mills, motors for driving same, and furnace alterations, are finished. Two tube-mills and ore conveyor are well under way. By the time these notes reach America the new mill should be in full swing. The officials concerned must be complimented on the excellent work done. Underground, everything is in readiness, and probably 22,000 tons per month, will be dealt with.

BUTTE, MONTANA

Butte & Superior.—Heinze Holdings.—Output for July. — Reins Copper Co. Suit.—Raven Assessment.

A. M. Chisholm, a heavy stockholder of the Butte & Superior, has returned to Duluth after having spent several days in the city looking over the property and interviewing stockholders, as to the best means of handling the property. Mr. Chisholm is a strong opponent of the refinancing scheme as recently adopted at a special meeting of the stockholders. He says that money could be secured through some zinc concern instead of issuing bonds. Although the Butte & Superior is pronounced by many mining men as the best zinc property in America today, it is heavily in debt, and has current debts to the amount of $400,000, one-half of which is due within 30 days. Where the money has gone many stockholders would like to know, but it is apparent from a statement recently made, that at least a portion of the money has been lost through bad management in operating. For instance, during the month of June, some 9000 tons of ore were mined, on which there was a loss of about $12,000, according to reliable reports. A metallurgist made an examination of the operations at the Basin concentrator, and reported that 55% of the mineral value has been lost in the tailing. Mr. Chisholm finds fault with the management in borrowing $250,000 from the American Metal company for the purpose of building a concentrator. The only work toward the building was the grading for the foundation, and the purchase of some of the structural steel, while the money has all been expended.

The Davis-Daly tramway from the Colorado mine to the Northern Pacific tracks, is ready for operation, but it is not known when any ore shipments will be made to the Basin concentrator. Development on a small scale is going on in the Colorado mine on the 1400 and 1800-ft. levels, and the cross-cut from the 1400-ft. level to the Hesperus, is being extended. If all reports are true F. A. Heinze is going to make some money out of his Stewart mine, in the Coeur d'Alene district. Over 200 tons of ore per day are being shipped to the smelter, making a profit of $500. In sinking a new shaft in the mine an orebody, which completely filled the opening, was discovered. The Butte-Ballaklava dividend of 50c. is being received this week, and some of the stockholders of the company are so jubilant over reports they have received, that they are predicting a dollar dividend within six months. The company at the present time is shipping 225 tons of ore per day.

According to the statements of Anaconda officials, the smelters at Anaconda and Great Falls are running to their full capacity on ore from the mines in this city, although there is no doubt that the number of men underground has been reduced, and that the quantity of ore being hoisted is much less than it was two or even one month ago. The miners' union officials are making the assertion that over 2000 men have been laid off, and that there is a reduction of about 3000 tons of ore per day. The reduction included the independent mines, such as the Tuolumne, Butte-Ballaklava, and East Butte. The Parrot has not been in operation for a long time, neither has the Rarus of the Butte Coalition company, or the Neversweat of the Anaconda group. Basing their opinion on general conditions and reports from the East, mining men believe that there will be a curtailment in this district of 25% in accordance with an understanding said to have been reached by all the big producers. The estimated ore tonnage and copper production by the different companies, in July, were as follows:

	Daily. Ore, tons	Month. Copper, lb.
Boston & Montana	3200	6,800,000
Anaconda	4400	7,900,000
Butte Coalition	1450	3,000,000
North Butte	1100	1,950,000
Original	500	1,100,000
Butte & Boston	550	950,000
Trenton	450	830,000
Washoe	450	725,000
Butte-Ballaklava	150	675,000
Tuolumne	100	275,000
East Butte	200	270,000
Parrot	150	260,000
Miscellaneous	50	120,000
Totals	12,750	24,855,000

John P. Reins, of the Reins Copper company, has commenced a suit against the company to recover on a promissory note for $20,000, on three assigned claims for services to the company. The note was executed at Pittsburg, April 28, 1908, by W. F. Johnson, treasurer of the company, and bears interest at the rate of 5% per annum. The assigned claims are as follows: G. L. Thompson, $736; R. S. Wilson, $717.50; H. C. Dahl, $833. The total amount claimed to be due, with interest, is $24,878.07. The Raven company assessment of 10c. per share, which was ordered a short time ago, is due and payable at the office of the International Trust company, Boston, August 15. By this assessment the company expects to receive enough money to pay off the bonded indebtedness, leave the property entirely free of debt, and to have a balance sufficient to carry on development for nearly a year. The shaft of the Raven has been sunk to a depth of 1500 ft., but it is stated that owing to the great inflow of water, little driving has been done, and cannot be until pumps are installed. In ordering the assessment the directors state that owing to the condition of the money market it was found impossible to renew or extend the mortgage bonds, so it was necessary for the company to take from its treasury the funds it had intended for use for development, and pay the bonds as they fell due. It is stated that the ore so far found in the shaft, it not of a quality to warrant mining, but it is hoped to find good bodies of ore as soon as driving can be done.

LOS ANGELES, CALIFORNIA

Southwestern Iron.—Skidoo Mine.—Pinmore.—The Oil Industry.

During the past week there have been persistent rumors, although no definite information, regarding the construction of a large blast-furnace and steel plant at Long Beach. Details are lacking, but it is stated that representatives of Harriman interests have spent several days in consultation with owners of large tracts of land near Long Beach. About two years ago the extensive holdings of L. S. Barnes, in Riverside county, comprising many acres of iron land, were purchased by Harriman interests; since then rumors have from time to time been heard regarding the construction of a steel plant. Judging from present activities it would seem that something definite is afoot, and information of interest is promised on the return of Mr. Barnes from the East. It is stated also that a foreign corporation intends to erect a plant on the coast, using oil as fuel. Whether or not anything materializes from these rumors, it is a certainty that valuable iron lands are to be found within comparatively short distances from the coast, and that there is a market here for the products of an iron and steel plant. The construction of such a plant would doubtless result in a saving to the consumer here, and a corresponding loss to the railroads that now receive the benefit of the long haul from Eastern points.

The Skidoo Mines Co., operating in the Panamint range,

Inyo county, has just received word from the mine of a discovery of a new orebody four to six feet wide and assaying about $20 per ton in gold. It is estimated that there is probably $100,000 worth of ore in this new body. This company has recently joined the ranks of the dividend payers, disbursing in July $50,000 as its second dividend. The mill is treating about 1200 tons of $12 to $15 ore per month and the monthly profit averages $7000. Work is to be discontinued on the Pinmore mine at Johannesburg until September. It is the intention of the operators, on resuming operations, to re-build and put in operation five of the ten stamps of the mill that was destroyed by fire some time ago. Work for the past year has been devoted chiefly to developing two veins on the 100 and 200-ft. levels, and it is stated that sufficient ore has been developed to supply five stamps for more than a year.

The great Lakeview gusher in the Midway field, Kern county, is said to have decreased to a flow of 22,000 to 28,000 bbl. per day during the past week, as compared with 25,000 to 30,000 bbl. during the previous week. The American Oilfields has brought in a gusher just west of the Lakeview. The initial flow was estimated at 25,000 to 30,000 bbl. per day and the last reports were that the well shoots oil 25 or 30 ft. above the crown-block whenever the gate is opened. The hot weather seems to have had little effect in decreasing activity in the Kern River country, The State Oil Co., Kern River Driller Oil Co., and the Bardole Oil Co., all under one management, are opening new ground. A rig is in place for well No. 1 of the State company, and material is on the ground for wells No. 2 and 3. Three wells are pumping on the property of the Kern River Driller Co. and a rig is up for the fourth well. Well No. 1 of the Bardole company is down 600 ft. The gusher of the Mays Oil Co. has decreased to a steady flow of 2000 bbl. per day and is said to be one of the best wells of the west side field. This company is drilling for another gusher. On the Green & Whittier lease, owned by the Associated Oil Co., about 150 men are employed. New boiler-houses are being constructed and the foundations are laid for several tanks. The old pipe-line that carried oil to the Standard Oil Co.'s tanks is being taken up; a new line, two miles of which has been completed, is to be laid. Drillers are at work on one or two of the old wells and material is being hauled in for new wells. The C. C. Midway Oil Co., operating on ground owned by the Santa Fe railroad, is drilling a number of wells and putting up buildings for men and stock. There are five wells in operation on the property of the United Oil Co. at Fellows; three strings of tools are being laid with which to drill additional wells. The Hawaiian Oil Co. is drilling two wells by the rotary process near Fellows and is said to be making good headway. The Lucks Oil Co. is drilling several new wells at the north end of the field. Several storage tanks with cement foundations have been erected. Material is being hauled to the lease of the Alma Oil Co. and preparations are being made to put down eight new wells.

In the Coalinga district the Silver Tip Oil Co. is expecting great things of well No. 2. During operations at the well last week, in the same formation as that cut in the No. 1 gusher, a sudden spouting of oil occurred, and for some time the fluid shot high above the derrick. This subsided after a few hours, however, owing to the sanding of the hole. The Creme Petroleum Co. has made a depth of about 2000 ft. on its well. A rotary drill is being used with good effect. The British Consolidated Oil Co. has acquired the Wabash property and is about to begin new development. There are now 17 producing wells on this property. A large force of men is busy constructing the necessary buildings at the camp of the Medallion Oil Co., operating in the Kettleman Hills district. It is expected that active drilling operations will be started by September 1.

Plans for the meeting of the American Mining Congress, September 26 to October 1, are being pushed. J. F. Callbreath, secretary, has been here in conference with the local committee. Public land problems are to form the main topic of discussion at the meeting.

NEW YORK

Effects of Liquidation.—Copper Curtailment.—Utah Copper Co.—Greene Consolidated. — Nevada Hills. — Mexican Development.—Porcupine.

In the panic of 1907 some of the New York bankers came to the rescue of the market and to the rescue of some of the corporations, at the time badly battered by the storm and fast drifting on to a lee shore. At that time there was a great deal said about the courage and the trustworthiness, of these saviors of the situation, these landmarks in time of stress; oddly enough there was little or nothing said of the salvage claimed by the rescuing parties. Surely the towing lines were sent out to disabled craft but just as surely as such craft were towed into calm waters, they sailed forth again under the colors of the rescuers and not those of the former owners. No one would say that the boy's rule of 'findin's is keepin's' is a cardinal principle of high finance, yet there were some happenings this week that if one had the temerity to suggest it, might appropriately be held within the rule. During the latter part of last year, a group of English and Canadian financiers, headed by F. S. Pearson, an engineer of high repute, an American by birth, but for a long time a resident of London, became heavily interested in the Rock Island railroad. The coterie of capitalists so engaged were known to be railroad men of ability, among their enterprises being the Mexican Light & Power Co., and the Mexican Tramways Co., the two concerns holding a practical monopoly of the public utilities of the City of Mexico, and the former being engaged in the construction of hydro-electric plants throughout the Republic of Mexico. The activities of Sir Weetman Pearson, of the great English contracting firm, in the oil business in Mexico, served to confuse the two in the minds of the public. Of the same name, the two are not connected in any way. The Pearson syndicate evidently nursed some very ambitious plans, some whose scope were far too wide to please some of the financial powers of New York. For the past six weeks or longer, it has been a matter of comment that there seemed to be an utter absence of inside support for a market, in which continued liquidation was becoming painful. It now appears that this recent course of the market was permitted to allow the Pearson syndicate to drift far enough toward the breakers to get beyond the point of haggling about the amount of salvage. This week saw the crisis, saw a market breaking five, ten, fifteen, in some cases, thirty points. The general Wall Street public was simply picking up the miscellany on its desk and, aimlessly and nervously, turning them over and putting them down in the same place, talking crop scare, copper weakness, and too many automobiles, while the real factors watched the Pearson syndicate try to unload under peremptory calls for margins. The storm promised to scatter wreckage all along the financial coast line, when Kuhn, Loeb & Co., and the Drexel-Morgan banking interests, steamed in and steamed out again with the materials for a new trans-continental railway, courteously taking the cargo of the syndicate as salvage. In 1907, when a very important New York Trust company found that the controlling interest in Tennessee Coal & Iron was more than it could carry and panic conditions became acute, it was Mr. Morgan who saved the day and in doing so saved Tennessee Coal & Iron for his U. S. Steel Corporation. With Mr. Pearson in various enterprises are associated Sir William Van Horne, of the Canadian Pacific, William and Alexander Mackenzie, both also of Toronto, Jose y Limantour, the Mexican Minister of Finance; Enrique Creel, Governor of Chihuahua, and others. The plan of the present operation contemplated a trans-continental railway system through a control of Rock Island, Lehigh Valley, Missouri Pacific, Denver & Rio Grande, Wabash, and Western Pacific, the whole to be operated in conjunction with a Mexican railway system to be joined to the Denver & Rio Grande. The something which has been hanging over the market was the burden of these operators; that the banking interests have been waiting for the opportunity, which has just come to them, goes without saying. A distinctly better tone now prevails, but the

question 'is findin's keepin's?' remains unanswered save by demonstration.

Next to the near panic, the important feature of the day is the determination to curtail copper production. Statements by the participants in the conferences of the producers held in London are comically cryptic. There are to be no admissions made that smack of conspiracy. John D. Ryan, president of the Amalgamated, and the acknowledged diplomat of copperdom, said, in a recent interview, "The representatives of many of the leading copper interests have been conferring in London, and the result is a better understanding among them regarding the copper situation. In fact, I may say there is a very general understanding among copper producers regarding the future output of copper." If that be treason make the most of it. What the effect of copper curtailment is to be is hard to conjecture. A 15c. copper, if maintained for any length of time, will stimulate production by smaller producers, now developing, who are no parties to any agreement, admitted or denied. Just how the present powers that be, are to maintain the price without creating numberless effective competitors, is one of the problems. The really effective weapons for complete control of the copper industry are the smelters and the selling agencies, these are in the hands of the Guggenheims and the Amalgamated principally, and if these are to be included in the understanding mentioned by Mr. Ryan, then curtailment may be made more effective than might at first glance seem possible.

The report of the Utah Copper Co. for the quarter ended July 30, has just been sent to press. The figures are interesting, as this is probably the last quarter, which will show record-breaking production for some months to come. The output was 25,124,052 lb. as against 18,511,619 for the quarter preceding and 13,291,210 for the quarter ended December 31, 1909. Earnings from the operation of the Utah Copper alone for the quarter were $1,192,551; dividends from Nevada Consolidated holdings, $356,428; dividend requirements were $1,149,616, leaving a surplus for the quarter of $399,363. The figures given will be interesting by way of comparison with those of the coming quarter in order to estimate the proposed curtailment of copper production. A 15% cut in output is to go into effect in Utah Copper and Nevada Consolidated; the latter now holds its place as producing the cheapest copper in the country. Nevada Consolidated's output for the quarter ended June 30, was 18,173,676 lb., produced from ore averaging 2% copper. The cost per pound for the quarter, after writing off $132,902 for depreciation of the Steptoe smelting plant, was 6.34c. as against 7.89c. for the preceding quarter. Net earnings for the quarter were, after paying interest on outstanding bonds and writing off depreciation, $1,147,796. Dividend requirements $746,479, leaving a surplus of $401,317.

The thawing out process was begun at the new smelter of the International Smelting & Refining Co., at Tooele, by William Spry, Governor of Utah, who went down from Salt Lake for the express purpose of striking the first match to light the fires. It will take about three weeks to get the first reverberatory furnace and the stack warmed up to a point where actual smelting operations can begin. The delivery of Utah Consolidated ores has been delayed by reason of the breaking down of the tramway and, in the meantime, shipments are to be made by rail, so that the ore-bins may be filled ready to feed the furnace by September 1, by which date shipments from the Giroux are expected to be going forward regularly to the smelter also. The ores of the Giroux will have to be carried for 150 miles over the Nevada Northern railway, which is controlled by the Guggenheims; contract for this transportation has not been arranged yet, but it is not anticipated that there will be any difficulty in making an agreement. The amount of the ore reserves of the Giroux, and the copper content thereof are not known, outside of official circles. Whether or not Giroux can produce copper at a profit on the present metal market is not known.

Adrian H. Joline, one of the leading members of the New York bar, has handed down an opinion as referee, in favor of the Greene Consolidated Copper Co., in a suit brought by the minority stockholders of the Cobre Grande Copper Co. of Arizona. This suit and two other similar suits were brought against the Greene Consolidated to recover certain properties and compel an accounting, under a claim that William C. Greene wrongfully deprived the Cobre Grande of the mines in controversy, in 1899, when Greene took possession of same and later turned them over to the Greene Consolidated Copper Co. The Yampa smelter at Bingham, Utah, is to be closed and the ores of the Tintic Mining & Development Co., and some of the ores of the United States Mining Co., amounting to about 800 tons per day, will be sent to the Garfield smelter in place of that previously shipped by the Utah Consolidated.

The ores of the Nevada Hills have been proved by tests to be so nearly identical with those of the Montana Tonopah, at Tonopah, that the method of treatment in operation at the latter property is to be adopted without change by the Nevada Hills' management. The East is taking a great interest in Nevada Hills in the hope that it is to prove a strong active market issue like Goldfield Consolidated. The expected deal in Florence failed to materialize and instead there has developed a small market manipulation in Jumbo Extension. The Eastern market looks upon the reported elimination of T. G. Lockhart from the active management of the Florence, and the election of A. D. Parker as president, with much favor. It has always appeared to the Eastern investor that Mr. Lockhart has been an obstacle in the way of broad-minded progressive development of the Florence.

There are some particularly favorable mine developments noted recently at Guanajuato. In the Tajo de Dolores mine, controlled by the Proprietary Mines Co. of America, five feet of ore has been opened in the west drift on the San Eusebio vein on the fifth level, which averages $67 per ton. This is bonanza ore and means a great deal for the property and for the camp at Guanajuato. The mill on the Dolores is being pushed to completion, 60 tons per week of freight going from the railroad station to the mine. The mill is expected to be in operation in December. The Pinguico Mines Co., controlled by the Securities Corporation, reports the opening of an entirely new orebody on the eighth level, and which has since been developed on the ninth and tenth levels, a great deal of which is rich enough to go direct to the smelter without treatment at the mill. Several cars have been shipped running $10,000 and $12,000 per car. The Oro Grande Mines Co., recently organized by the Securities Corporation, as one of its subsidiaries, is paying a semi-annual dividend of 3% on its preferred stock. This company acquired the mill and the ground of the Guanajuato Amalgamated Mines Co., known as the Adams property. When this concern was taken over it was appraised on the value of the milling plant alone. Exploratory work in the mine has since developed a considerable body of milling ore, which will aid materially in furnishing a satisfactory tonnage to the mill. The increased price for silver and the improved tone in the silver market has given new courage to the operators at Guanajuato, and has perceptibly increased the interest in Mexican enterprises throughout the East. The industrial development of Mexico is being watched with increasing interest. The transportation question is recognized as being of as great importance as the development of the various mining camps, and the work of building roads and the installation of hydro-electric power plants, will greatly stimulate the mining industry. Richard Honey, the iron manufacturer of Pachuca, who is building the Pachuca & Zimapan railroad, has recently been granted a concession to build a railroad from Pachuca to Mazatlan, and is preparing to start work on the new road.

The five-stamp mill on the Timmins property at Porcupine, is continuing to show encouraging results. A 30-stamp mill has been ordered by the Timmins syndicate, and the belief seems to be growing in the permanence of the camp. A standard-gauge road is to be built from a point on the Temiskaming & North Ontario railway to the Metagami river, a distance of about forty-two miles.

General Mining News

ALASKA

(Special Correspondence).—That the Iditarod is a rich camp, though at present handicapped by crude methods and lack of capital, is the conclusion of first authoritative reports just received here direct from the newest gold region of Alaska. The clearest and most hopeful statement of conditions was made by Herbert L. Jaffe of Seattle, in reports to M. Robert Guggenheim, whom he represents. Mr. Jaffe says there is much excitement but little money in the camp. Prices are high for everything. Wood is $40 per cord, bacon 75c. per lb., and meals $1.50 to $3 each. Nevertheless, he says, the gold is there, and plenty of it. He estimates that five or six of the eight creeks will yield from $5,000,000 to $6,000,000 each, a probable total of $35,000,000 to $40,000,000. Mr. Jaffe strongly favors the district for dredging operations, like those at Nome. He says the ground can be handled for not more than 30c. per cu. yd., while operations so far prove that the pay is from 75c. to $5 per cu. yd. Some rich ground has been found, and there are instances of pans of gravel running $30 and even $40. Bob Martin, a well known Alaskan, sold one of his claims on Black Creek for $5000, and the new owners a few days later made a preliminary clean-up of $2800. Bedrock is seldom more than 20 ft. down, and the pay-streak varies from one to seven feet in thickness. Operation is possible both winter and summer.

Seattle, July 30.

ARIZONA

COCHISE COUNTY

A tank has been placed at the 1385-ft. point in the pump compartment of the shaft, at the Denn-Arizona, to catch the water above that level. A 100-gal. pump is used in sinking the shaft, which is going down at the rate of 15 ft. per week.——In the Dragoon district, which has been largely prospected for copper ore, Oliver Merrill has cut a 10-ft. vein at a depth of 70 ft., that assays $8 per ton gold. Drifts are being driven on the shoot, and a winze sunk in the ore.——A rich discovery is reported on the claims of Cummings & Wolcott, in the Courtland district, and 35 sacks of the ore have been shipped to the smelter at Douglas, to determine its value.——The Texas-Arizona Mining Co. has ordered a consignment of new machinery, which will be installed at the mine, northeast of Dragoon, in a short time. The ore is principally a silver sulphide, though some lead and gold have been found at places in the shoot.——New equipment has been forwarded to the Bisbee Coalition Mining Co., which is a consolidation of the North Bisbee and the Eureka Mining companies, in the Warren district. There is over 1000 ft. of development on the ground from which several lots of 17% copper ore have been shipped.

GILA COUNTY

(Special Correspondence).—The McGaw shaft on the property of the Superior & Boston Copper Co. is at a present depth of 761 ft. from the collar or 210 ft. from the sixth level. The stopes from which most of the ore is coming at present, are on the sixth level, about 320 ft. west of the shaft. Little or no timber is used, and with the exception of one man at the central chutes, no handling of the ore is necessary.——With the exception of the curtailment of development, things at Miami are progressing as usual. It has been definitely decided to use Deister No. 2 and No. 3 tables in the mill, exclusively, and the Nordberg hoists at the main shaft are being installed.——At the property of the Lost Gulch United Mines Co., the three lodes, Tiger, Badger, and Bonanza, are being exploited. The drift on the Tiger is in gold ore assaying about $30 per ton. The adit to open the Badger and Bonanza lodes is ultimately to be 1200 ft. long, and is now 1100 ft. from the portal.

Globe, July 29.

MOHAVE COUNTY

Another rich discovery was made at the Tom Reed mine, in the San Francisco district, a few days ago, when a 5-ft. shoot of high-grade ore was opened on the 300-ft. level, about 800 ft. from the main shaft in the western portion of the mine. The foundation for another battery of 10 stamps is completed, and a new tube-mill and compressor, have been installed.——A second consignment of $150 ore has been forwarded from the C. O. D. mine, and a new Cameron sinking pump placed in the shaft.——The Arizona Turquoise Co., which has a bond on the IXL mine, has taken a hoist to the property and is cleaning out the old shaft.——Work at the Cyclopic is progressing rapidly, and the main shaft is expected to reach the 300-ft. point in a short time.

YAVAPAI COUNTY

The Mount Elliot Consolidated Mining Co., of Chaparral, recently shipped a $3250 bar from the last clean-up, and approximately $4000 worth of concentrate. The company has just completed the installation of a 5-drill compressor, and the electrification of the entire plant.

YUMA COUNTY

(Special Correspondence).—There is little activity in the immediate vicinity of Bouse, at this time, although several companies are preparing to resume operations in September. The Mudersbaugh property, consisting of 34 claims, lying about eight miles south of Bouse, has been purchased by George Mitchell, of Los Angeles. It is said that men are now on the ground to begin development.——The Little Butte Consolidated and the Pay Car Mines Co. expect to resume operations in September. The former will construct a mill in the fall. The property of these companies lies just to the west of Bouse. J. C. Denton, who will have charge of work for the Pay Car company, has recently purchased the Sunshine and Free Gold groups, comprising 11 claims, lying four miles west of Bouse. These have been turned over to the Pay Car company, bringing that company's holdings up to 65 claims.——Finney & Brooks, of Los Angeles, have begun work on a gold prospect about twenty miles north of Aztec. Down to the present depth of the shaft, 50 ft., ore carrying $16 per ton in gold has been developed. The ore occurs in a wide zone of silicified rhyolite. It is purposed to sink the shaft to a depth of 100 ft., and determine by cross-cuts the width and tenor of the orebody at this depth. Two shifts are at work.

Bouse, August 1.

CALIFORNIA

AMADOR COUNTY

The drift on the 1200-ft. level of the Central Eureka, near Sutter Creek, is reported to have opened a 10-in. shoot of high-grade ore 150 ft. from the shaft.——The machinery for the erection of a 4-stamp mill is being hauled from Martell to the Whitmore mine, near Volcano, and the property will be thoroughly prospected. There is considerable ore on the dump that will be run through the mill at once.

INYO COUNTY

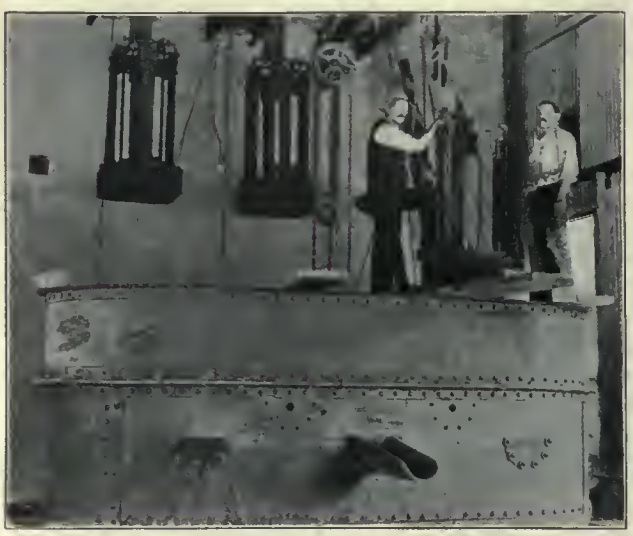
During June, the Tecopa Consolidated Mining Co., in the eastern part of the county, shipped 116 carloads of $16 ore to the smelters. Of this 70 cars went to the American Smelting & Refining plant, at Salt Lake, and 46 to the Needles smelter.

NEVADA COUNTY

The new concentrator building, at the Erie mine near Graniteville, will be completed in a short time, and the concentrators installed. It is thought that this will make a considerable saving as the ore contains a large amount of pyrite.——John Langman, Frank Bishop, and associates, of Nevada City, have located 160 acres of gravel land at You Bet, and will attempt to re-work the ground that proved so rich in the early days of that district, when hydraulic operations were permitted.——New machinery is being installed at the old Wisconsin mine in the Graniteville district, and the shaft, which is reported to be 150 ft. deep, will be unwatered. Fred Medlin is manager.

SHASTA COUNTY

Though the closing of the Bully Hill smelter, at Winthrop, has thrown a large number of men out of work, there are over 100 employed in the Bully Hill and Rising Star mines, the company shipping about 100 tons per day to the Mammoth smelter.——After a two weeks' continuous run, the Heroult iron smelter, on Pit river, has closed down, and five additional furnaces will be erected. The Northern California Power Co., which furnishes electricity to the



Heroult Smelter in Course of Construction.

smelter, will have the plant near Ball's ferry completed this fall, making 20,000 hp. available. A carload of the pig iron produced in the last run, has been shipped to the Columbia Steel Co., at Portland, Oregon.

SIERRA COUNTY

Fred H. Pearson has obtained a bond on the Independence mine, on Wolf creek, and will unwater the shaft, which is down 180 ft. The ore in the upper level is reported to be high grade.——Richard Phelan, of Sierra City, is having the assessment work on his claims in Slug canyon completed for the year.——Curtis Lochlin, of Nevada City, examined the Empire mine, in Gold valley, for Eastern capitalists. The property is equipped with an electric plant, hoist, and mill, though it has been idle for the past two years.——Adam Kieffer has repaired the gasoline engine at the Gilbraltar shaft, and two shifts will be started unwatering the ground. When this is completed the drift will be driven under the channel.

TRINITY COUNTY

At the Oversight mine, owned by A. H. Wolf, and associates, on the Yellow Jacket creek, a branch of the east fork of the Trinity river, some high-grade free-milling ore has been taken out recently. In the same district is the Alaska mine, and the Yellow Jacket, owned by R. L. Carter, Jesse Turtelotte, and L. H. Boyd, of Weaverville. Though only a small amount of development has been carried forward on this claim, several stringers of high-grade ore have been opened.——On Rattlesnake creek Armstrong & Liebbrandt, of Santa Cruz, have a good prospect. They are now treating a free-milling ore, with considerable galena, in a 5-stamp mill. King & Bailiss, who have a group of placer claims in the same district, have just cleaned up, as the water is getting too low for operation.——The great La Grange placer mine is also short of water, and the reservoir has to be allowed to fill before piping. The ground caves at the working face in such quantities that it is seldom necessary to move a giant more than once a year. Much fine gold escapes, but the La Grange company owns the valley of the north fork, and will not allow anyone to attempt to work the tailing.

TUOLUMNE COUNTY

(Special Correspondence).—The mill at the Donella, near Arastraville, began crushing ore last week. The quantity if ore in readiness is estimated at 400 tons, and, it is said, will average well in free gold. Development is being continued and the outlook is good.——The working force at the Jumper is being increased as fast as additional men can be employed advantageously. It is understood the company contemplates many changes, with a view to economy in the working of the mine and the reduction of the ore.

Tuolumne, July 30.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—Advices received from Boston are to the effect that the Kelley property, on Democrat mountain, has been sold to Mr. Milliikin, a mining engineer of New York, for a consideration of $380,000. It is understood that work will at once be put under way in the advance of the adit which is in 2800 ft. The 50-ton mill will be remodeled and enlarged to treat 150 tons per day. The property was owned by H. O. Marcey of Boston.——A deal has been closed whereby C. D. Runkle and C. W. Draper secure the Colorado Central group of mines, under bond and lease. A force of six men has been put to work, and as fast as the workings have been placed in shape, more miners will be given employment. Drifts have been started on the Equator vein through the Marshall adit, a body of rosin zinc being followed that is from 3 to 7 ft. wide. The bond runs until December 1.——M. Bonheim & Son report that a 3-in. streak of ore has been uncovered in the south drift on the North Star vein, East Argentine district. Assays run 6 oz. gold and 973 oz. silver per ton.——More than 200 prospectors have been at work on Bard creek, and during the past two weeks, over 500 locations have been made. The camp of Beshear has been established, and a townsite is to be laid out. The new goldfield is almost five miles directly west of Georgetown. Cripple Creek miners were first on the ground.

Georgetown, July 30.

GILPIN COUNTY

(Special Correspondence).—Shipments have been started from the Two-Forty mine in Russell district. The ore is a medium grade and mills from $22 to $25 per ton in gold.——A. Merrick, manager of the Schiller mine, states that a 6-in. streak of ore has been uncovered in the bottom of the 90-ft. shaft, that contains 28% copper, with fair amount of gold and silver.——The Gilpin Orion Gold Mining Co., operating in the Bobtail district, through its manager, W. E. Meagher, states that a shaft-house will be erected and machinery ordered.——The machinery for the new mill of the Golden Sun Mining & Milling Co., has been shipped, and will arrive during the coming week. The building is practically completed.——An air-compressor is to be installed at the Grand Union property, on South Boulder creek. The erection of a mill is being considered.

Central City, July 29.

GUNNISON COUNTY

Work has been started at the Excelsior property, in Baxter basin, the air for the drills being furnished by the compressor at the Augusta, a line from which was laid when the adit was started. It is thought that the adit will open one of the ore-shoots within the next two months.——It is reported that a smelter will be erected at the Star mine, at the base of Italian mountain. The plant will be situated within a mile of the Denver & Rio Grande line to Crested Butte. The ore is practically self fluxing, and contains a high percentage of lead.——Morner & McGruder have commenced work on their property on Baldy mountain, and will ship a trial lot of the ore to the smelter at Buena Vista.

LAKE COUNTY

A. E. Davis, who is leasing on the Big Six, at Leadville, is shipping a carload of ore per day.——In South Evans gulch, eight men are working at the Blanche, trying to pick up the shoot that produced rich ore in the early history of the property.——From the Ollie Reed, the lessees are shipping 200 tons per month.——It is reported that work will be resumed at the old Homestake mine.——The north end

of the Fanny Rawlings claim has been unwatered, and the work of sinking the shaft another level of 75 feet, started. ——The lessees of the Gold Basin are working on the 450-ft. level, the ore at that point being similar to that found on the 350.——The Wolftone, on Upper Carbonate hill, is shipping 3500 tons per month, and the Castle View 1500.——The drift that was started a few weeks ago on the lowest level of the Cleveland, has opened the vein in the granite, showing it to be of similar size and value as in the porphyry and quartzite.

OURAY COUNTY

The development at the Calliope mine, in the Ouray district, since the old workings have been drained, has opened six feet of high-grade ore in the quartzite. The ore is gray copper, with brittle and ruby silver, portions of the vein assaying over 2000 oz. silver per ton.——Work has been resumed at the Legal Tender shaft, and it will be sunk to the contact as quickly as possible, drifts being driven from that point to the adjoining Mineral Farm ground.——Development at the Thistledown is opening a higher grade ore than in the past, the material now coming from the stopes being almost double in value that which was taken out a short time ago. The mill is running one shift, and the problem of slime-loss is being rapidly overcome.

TELLER COUNTY

A shoot of rich ore has been opened on the 300-ft. level of the Stratton's Independence, and a carload shipped that averaged 13 oz. gold per ton. The vein is in the granite. ——The fires have been started under the boilers at the Camilla mine, by the Uncle Sam Leasing Co., and the shaft will be sunk from the 200 to the 350-ft. level.——Thomas Keegan, and associates, operating a lease on the 600-ft. level of the Blue Bird mine, shipped five carloads of ore during July, the coarse rock averaging $56 per ton, and the screening $71. The vein at this point is three feet wide, and it is believed that the lessees on the 500-ft. level have cut the same shoot.——The Jolly Jane Mining Co., owning 14½ acres on Beacon and Bull hills, is being reorganized, and work will again be started on the property. Recent finds in the adjoining Tecumseh ground have led the stockholders of the Jolly Jane to believe that their ground may prove rich.——The Vindicator Consolidated Mining Co. has mailed the quarterly dividend of 3c. per share, and report for the quarter, to the stockholders. The report reviews the development during the past three months, tells of the discoveries on the 1300 and 1400-ft. levels, and states that the directors of the company contemplate sinking to the 1600-ft. level.——Cobb & Von Tilborg, leasing on the 300-ft. level of the Doctor-Jack Pot, recently shipped several carloads of $25 ore.——Sinking has been resumed in the Golden Cycle shaft at the 1400-ft. level, and will be continued to the 1700. A No. 9 Cameron sinking pump is used to raise the water to the sump on the 1400.

IDAHO

IDAHO COUNTY

(Special Correspondence).—The Elk City Mines Corporation, controlled by J. T. Omo, W. H. Stowell, R. A. Koontz, and others, of Spokane, has acquired a partly developed mine on the south fork of the Clearwater, fifty miles from Stites and six miles from Elk City. When purchased by this company the property had a 5-stamp mill and about 1000 ft. of development as adits on a 15-ft. vein. The mill is being rebuilt and enlarged to a 10-stamp plant, to have amalgamating plates and tables. The ore consists of quartz, containing free gold, and gold and silver in sulphide material. It is said to contain telluride worth $1195 per ton.—A raise from the No. 4 adit at the Jumbo mine, in the Buffalo Hump district, opened a shoot of ore, two feet of which assay over $100 per ton, when up 30 ft. This is thought to be the extension of the shoot worked from No. 1 adit, and should this prove true, the company will have about 700 ft. of backs.——No. 3 adit at the American Eagle group, in the Elk City district, opened a body of high-grade ore.——In the Orogrande district, the cyanide plant has been completed, and the mill is crushing 85 tons of ore per day.——A saw-mill is in operation at the Iola, and work has been started on a small crushing plant. ——The shaft at the Gilt Edge, in the Ten Mile district, is down 114 ft., and a cross-cut has been started toward the ore. A power-plant and pump will be installed as soon as the wagon-road to the mine is completed.

Elk City, July 21.

SHOSHONE COUNTY

The Hypotheek mine, situated three miles south of Kingston, has been developed by a 600-ft. adit on the vein; and by a 1000-ft. shaft that was sunk near the breast of the adit. This shaft cuts through the vein on its dip. There has been about 1000 ft. of driving on the vein from four stations. The property is managed by H. E. Herrington. ——Harvey M. Ross, secretary and manager of the Nabob mine, near Kellogg, reports that all the machinery has been installed, and work on the long adit will be resumed in a short time. He said, also, that the shaft on the ore is down 365 ft., with drifts on the ore from the 100, 200, and 300-ft. levels. It is figured there will have to be a cross-cut of 2700 ft. from the side hill to reach the orebody. This will give a depth of 500 ft., and will drain the shaft, which is full of water. The breast is in 336 ft. The company has just disposed of a block of 500,000 shares, giving it ample funds to place the property on a producing basis.——Charles H. Bell, of Spokane, president of the Best Chance Mining Co., whose claims adjoin the H. E. M. property, near Wallace, has received advices that the cross-cut adit, now in 760 ft., cut a vein of quartz and galena a few days ago. The ore was opened at a depth of 450 ft., and 2500 ft. west of the main workings on the H. E. M. There are 12 claims in the group, which lies a mile and a quarter up Dago Peak gulch from the Oregon Railroad & Navigation Co.'s tracks.

KANSAS

CHEROKEE COUNTY

The Boston company, at Galena, has recently completed a 300-ton mill, on a lease of the Delta land just east of the tract of 400 acres purchased by the company some time ago. The plant is one of the best equipped of any in that camp, having three concentrating tables, sand jigs, motors for hoisting, and is run by a gas engine. A centrifugal pump has been installed to raise the water. The ore is taken from an open pit, pay-dirt being taken from 10 ft. below the surface. Only a trace of lead is found, zincblende being the main ore. The company will install a steam-shovel in the near future, and will later work the deep deposits for sheet ore.——The Diplomat mill will be ready to start operations within two weeks, the electric wiring having been finished, and an air-compressor is ready for installation. When completed this plant is expected to become one of the chief producers in the Galena camp, as it has opened one of the most promising orebodies found in that district.——A tailing-mill is being operated by James Murphy, at North Empire, and already a surplus of 200 tons of high-grade zinc ore has accumulated in the bins.——A contract has been let for the erection of a 500-ton plant for the Omaha-Petersburg company, in the Baxter Springs camp, the mill to be one of the best equipped in the camp, and built along the sizing system, which has proved efficient for the Eastman company. Four shafts are in ore, and a fifth now under way at the mill.

Galena, July 29.

MISSOURI

JASPER COUNTY

(Special Correspondence).—There have been numerous finds in the district the past fortnight, some of which have been important. Northeast of Joplin near Turkey creek the Brattleboro Mining Co. entered rich ore at the 76-ft. level where the cuttings assayed 37%.——A new company has taken a lease on the old Talisman land at Carterville, and after a small amount of prospecting, has found a very high grade of soft-ground ore in the roof of the old drifts above the former working levels.——One of the best calamine

discoveries reported for some time has been made on the Saddler Mining Co.'s land at Duenweg, recently. The ground is not far from the McGee silicate mines which are the richest silicate producers in the district.——John Durby has made a rich find in four drill-holes recently sunk in the Porto Rico camp.

Joplin, July 23.

NEVADA

ESMERALDA COUNTY

The Red Top Extension Mining Co., which owns the Bull Dog fraction in the centre of the Goldfield district, is to resume work, a contract having been let for work in the shaft and additional cross-cutting. The main shaft is down 600 ft. and this will be sunk to the 1000-ft. level, while a cross-cut is driven at the 700-ft. level to a point under the 200-ft. shaft and a connection made. Considerable $9 ore has been blocked out in the property, and the operators hope to develop enough high-grade to warrant milling all this.——A syndicate had been formed to open the Rustler ground which is known as the Goldfield Florence Extension, and an attempt will be made to find the extension of the Little-Florence shoot which is supposed to cross this ground.

NYE COUNTY

(Special Correspondence).—The Pioneer lease is sending ore to the Mayflower mill from the 240-ft. level. The main stope at this point is 10 ft. wide and 40 ft. high, and has been carried forward about 60 ft. The ore is being mined in the north of the old stopes, beyond the Stark fault. This was formerly regarded as barren territory. Owing to the scarcity of water, the mill is only running at part capacity, the only source of supply being the Mayflower mine, which is being unwatered in the effort to secure 7200 gal. per day.——The Eclipse Development Co. has picked up the shoot in Tramp Consolidated below the fault. The company has driven 335 ft. on the Eclipse vein to an approximate depth of 500 ft. from surface. The extent of the new shoot is undetermined, but assays $15 to $20 per ton, about the same class of ore as that found in the upper levels. A winze will be sunk from the drift, and an electric hoist and two machine-drills installed. The 10-stamp mill is running on ore from the old workings. Harry G. McMahon is superintendent.——The Bennett-Shively lease on Tramp No. 5 has opened a shoot of ore said to assay $80 per ton, at a depth of 25 ft., 35 tons of which will be shortly treated by the Eclipse mill.——The west foot-wall drift on the 400-ft. level of Tonopah Extension is out 900 ft. and will connect with the western workings within 45 ft. The first of the three veins in this portion of the mine has been cut. It is three feet wide with milling-grade ore. The mill is handling 120 tons per day and the company is earning net profits of $18,000 to $20,000 per month.

Rhyolite, July 29.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence).—The annual shut down of the Ernestine Mining Co. for general repairs and improvements has been in evidence the past two weeks. The entire plant will again be in operation at an early date.——Sinking of the shaft at the Deadwood mines continued until the past week, when work was temporarily abandoned on account of the inflow of water. The crew has since been engaged in both the north and south drifts of the 400-ft. level.——The third Burt filter was delivered to the Socorro mines on Fannie hill during the week. When installed this will increase the capacity of the plant 30%. The June shipments of refined gold and silver bullion exceeded 32,000 oz. in addition to heavy consignments of concentrate. Approximately 3000 tons of ore were milled.——The mine crew of the Helen Mining Co. has been increased to 15 men, which will be further added to in a short time, the work at present being cleaning out and retimbering portions of the old workings preparatory to general development. Good headway is being made on the installation of the pipe-line up Whitewater creek.

Mogollon, July 22.

OREGON

BAKER COUNTY

The Oroville Gold Dredging Co. which has secured a bond on a large acreage in the Sumpter valley has commenced drilling the ground to test its value. The work will be in charge of C. W. Bigelow.——The annual meeting of the Listen Lake Gold Mining Co., operating the Listen Lake mine in the Greenhorn district, was held recently at Baker City. The company has installed a power plant and hoist within the last few months and is blocking out a good grade of milling ore.——E. N. Brigg and G. N. Start are examining the Ibex mine in the Baker City district and will reopen the property if the examination warrants.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—That the Dominion of Canada is fast becoming a cardinal factor in the world's production of the precious metals, is easily proved by some figures recently compiled, which go to show that the mineral production of the Dominion of Canada during 1909, amounted to over $92,000,000, of which nearly one-half was exported. The gold production amounted to approximately $10,000,000; copper, $9,000,000; silver, $12,000,000, coal over $5,000,000. The Cobalt district produced practically all the silver. At the present time about 28,000,000 lb. nickel matte is sent to the United States for treatment, and an attempt will be made to provide facilities for the smelting of this product within the Dominion.——On the Old Mike group, in the Bayonne district, a 100-ft. adit has been driven under the Carolina, and a good body of ore opened. A ditch, 1200 ft. long, has been constructed to the Grant-Monaghan property, with a view to sluicing off the surface soil and uncovering the vein.——S. S. Fowler, managing director of the Blue Bell zinc property, has returned from a consultation with the capitalists behind the company, in France, and it is announced that operations will be resumed at the property at once.

Rossland, July 30.

MEXICO

CHIHUAHUA

The new mill of the Lluvia de Oro mine is now being driven by the power plant completed in June. The property is expected to produce $2,000,000 in bullion and concentrate per annum.

GUANAJUATO

The Nueva Luz shaft of the Proprietary Mines Co. of America, has reached a depth of 600 metres, and a cross-cut has been started toward the vein. The distance is estimated at 900 ft. and work will be advanced at the rate of 150 or 200 ft. per month. In 1902 this work was started by the Mineral Development Co. which later was subsidized by the Mexican Government, ₱150 per metre for each metre below the 500-metre point being paid to the company. The work was stopped in 1907 on account of the financial stringency and resumed in 1908 by the Proprietary Mines Co. of America, the work being in charge of Carl Heinrich.——The cross-cut at the Humboldt mine has opened a stringer of rich ore and it is expected to tap the vein within a short distance.

HIDALGO

Work has been commenced at the Santa Inez Carretera property in the Pachuca district and the shaft is down over 20 metres. The contract calls for the completion of a 250-metre shaft within 10 months and a 75-hp. electric hoist will be installed at once to facilitate the work.——The Real del Monte company is concentrating work on the San Ignacio shaft which is being lined up and retimbered to the 525-metre level. The shaft was sunk on the dip of the vein and makes a number of angles, so rapid hoisting has been impossible. The company is to install a 250-hp. electric hoist and use self-dumping skips.——Pumping has been started at the Sonora y Ures company's shaft and sinking will be resumed as soon as the mine is drained. The company will issue 1000 shares of stock to provide the necessary capital for this work.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

STATE SECRETARY OF MINE INDUSTRIES

The State Secretary of Mine Industries provided for by the statute of Kansas creating the State Association of Miners, is ex-officio State Mine Inspector and is a 'public officer.'

Titus *v.* Sherwood, (Kan.) 106 Pac. 1070, Feb. '10.

CONSTRUCTION OF OPTION CONTRACT TO PURCHASE MINE

On January 17, 1907, Caine and Junghandel secured a 60-day option contract from the Ludwig Copper Mining Co. for the purchase of certain of its copper mines in the State of Nevada at the stipulated price of $1,000,000, provided they paid $5000 within 30 days; the remaining payments in case of sale to be made at stated intervals. On February 7 following, Caine and Junghandel sold and assigned said option contract to F. J. Hagenbarth in consideration of $200,000, $10,000 in cash; $40,000 to be paid at the time of making the first payment to the Ludwig company; the remaining $150,000 to be paid in proportionate amounts on the dates when the other payments were to be made to the Ludwig company. Hagenbarth paid Caine and Junghandel $10,000 cash and also advanced $5000, the sum necessary to continue the option in force beyond the 30 days, making a total payment of $15,000. Hagenbarth after causing the underground workings of the mine to be examined by experts refused to take up the option and refused to purchase the property in question and made no other payment. When the first payment on the option contract became due to the Ludwig company, Caine and Junghandel demanded of Hagenbarth the payment of the $40,000 according to the agreement, and when the second payment on the option became due they demanded from him the second payment of $50,000, and on refusal to pay they instituted suit to recover on their contract of assignment. Under this state of facts the Supreme Court of Utah on appeal, reversing the decision of the lower court, decided that the assignment did not bind Hagenbarth absolutely in all events to pay the balance of the $200,000 consideration, but his liability for such amount was conditional on his completing the option, and thereby becoming obligated to pay the Ludwig Copper Mining Co. the installments and purchase price for the mine; and Hagenbarth having elected not to take up the option was not liable to Caine and Junghandel for the balance. The Court also held that the contract was not so plain as to preclude the admission of evidence of the surrounding facts and circumstances.

Caine *v.* Hagenbarth, (Utah) 106 Pac. 945. Feb. '10.

LOCATION OF MINING CLAIM—NOTICE

The statute of Wyoming provides that before filing the location certificate the discoverer shall designate the location by posting at the place of the discovery on the surface a plain sign or notice containing the name of the lode or claim, the name of the discoverer or locator and the date of such discovery. The statute gives the locator 60 days from the date of discovery in which to sink the discovery shaft. Under this statute notices were sufficient which were properly posted at the place of the discovery reciting that the undersigned on a stated date located and claimed a certain lode described, extending a specified distance east and west, and gave the name of the claim upon each side of the place where the notice was posted, and where such notice was placed in the shaft-house and another to the same effect was placed on a slab on the claim. Such notice was not invalidated by the fact that it was posted after midnight of the date it bore, in the absence of fraud, and when it was so posted before the initiation of any conflicting claim. The statement that on the date mentioned in the notice the locators located and claimed the lode to the extent described was a sufficient statement of the date of the discovery.

Bergquist *v.* W. Virginia-Wyoming Copper Co. (Wyo.) 106 Pac. 673, Feb. '10.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

M. L. REQUA is in New York.

A. C. LAWSON has gone to Nevada.

L. J. PEPPERBERG has gone to Utah.

J. H. BAKER has returned from Mexico.

R. B. HEGARDT is at Long Beach, California.

C. C. SEMPLE is at New Canaan, Connecticut.

C. COLCOCK JONES is in the Ventura oil district.

J. F. CALLBREATH, Jr., has been in San Francisco.

H. S. MULLIKEN, of Mexico, is at the Holland House, New York.

CHARLES E. VAN BARNEVELD was in San Francisco this week.

W. J. LORING was in Kalgoorlie, but has returned to Melbourne.

W. M. CLAYPOOL has returned to Berkeley from Hollywood, California.

N. S. KELSEY has returned from the Atlin district, British Columbia.

E. C. WOLSELEY, of the Balaklala Con. Copper Co., is in San Francisco.

M. L. NEBEKER is superintendent of the Stewart mine at Wardner, Idaho.

GEORGE MILTENBERGER, JR., of Philipsburg, Montana, is at Portland, Oregon.

F. A. SCHIERTZ left Shanghai August 1 for Boston by way of Hamburg.

ARTHUR L. HAMILTON, formerly of Fairbanks, Alaska, has moved to Chicago.

JOHN A. GROSS has left Walla Walla, Washington, and gone to Atlanta, Idaho.

E. E. BARCHARD has been appointed manager for the Santa Gertrudis South Co., Ltd.

J. J. STANFORD has opened an office at Wallace, Idaho, for mining engineering practice.

ALBERT BURCH will be at Bellingham, Washington, for two weeks on professional business.

CHAS. P. RICHMOND has returned from Salvador, C. A., and is now at Pomona, California.

M. S. GRIFFITHS is general manager for O. y T. Braniff, Cadereyta de Montes, Queretaro, Mexico.

FRED T. WILLIAMS has gone from Park City, Utah, to Idaho for two weeks' mine examination work.

H. B. PRICE is now mill superintendent and ROBERT GORDON is mine superintendent of the Montezuma Mines of Costa Rica.

ARTHUR REICHE, general manager for the Orenstein-Arthur Koppel Co. in the United States, is expected in San Francisco in August.

W. S. BOYD, who was with the Utah Copper Co., at Bingham Canyon, Utah, is now with the Ray Con. Copper Co. at Kelvin, Arizona.

J. A. MACKILLICAN has resigned as manager for the Michigan & Montana Development Co., Wickes, Montana, and is at the Comet mine, Hailey, Idaho.

A. C. DART has resigned the professorship of mining engineering at the Wyoming School of Mines to become general manager for the Rambler Copper & Platinum Company.

W. R. WARDNER has resigned as general manager for the Golden Star Mines Co., Polaris, Arizona, and will engage in general mining engineering practice with offices in the Bradbury building, Los Angeles, California.

GEORGE S. BINCKLEY, who has been in charge of an extensive installation for the British Columbia Railway & Power Co. the past few years, having completed his labors, is about to return to his professional practice at Los Angeles, California.

OIL DIVIDENDS FOR JULY, 1910.

From the Official Monthly Statement of Oil Securities of the San Francisco Stock Exchange.

Company.	Capital.	Shares issued.	Par value.	Acreage.	Location.	Dividend. Last date.	Amount per share.	Total to date.

NEW YORK METAL MARKETS

L. Vogelstein & Co., under date of July 28, issued a circular containing the following regarding metal prices:

The outlook for metals has lately become more encouraging. This is particularly true of copper where a common sense policy seems likely to be substituted for cut-throat competition. Though the effect of reduced production will not be reflected in statistics for two or three months to come, we are in a position to confirm the report that producers will curtail their output and it looks to us as though purchases of copper metal at present prices ought to be more attractive than copper shares, at least for those who have missed the opportunity to buy at the bottom, because shares have already recovered 10 to 15% from the low point, while Standard Warrants in London have advanced only about 55 shillings, or less than 5%, and electrolytic copper in New York barely ¼c. per lb. or 1%. Spelter by its resistance to further declines gives promise of responding freely to improved conditions. A price of 5c. for this metal, like 12½c. for copper, seems to mark the bottom. Lead, while doing better of late, is susceptible of further improvement. Tin, not having previously declined, is in an uncertain position. Without knowing the intentions of the Tin Syndicate, the future is hard to predict, but apparently liquidation, unless forced, will not be encountered. Currently there is a good volume of business.

JOPLIN LEAD AND ZINC

The *News Herald* figures for the week ended July 23, 1910, are as follows: The high price for blende was $44 per ton, and the average on all lots was $38.33, compared with $38.20 for the previous week. St. Louis spelter was strong at $5.10 compared with $5.025 close of the preceding week. Calamine ores brought as high as $27 on an assay basis of $24 for 40%. The basis ranged down to $20, the average price per ton compared with last week's quotation of $26.70. The average price for lead ore was $48.17 compared with an average of $48.62 last week. The high price was $49, pig-lead closing at $4.35. The value of shipments from each district was as follows: Joplin: Blende, $44,733; calamine, $588; lead, $5,234. Total, $50,564. Webb City-Carterville: Blende, $76,701; lead, $17,052. Total, $93,843. Galena: Blende, $6,853; lead, $1,323. Total, $8,176. Granby: Blende, $8,881; calamipe, $6,975; lead, $365. Total, $16,221. Duenweg: Blende, $10,491; calamine, $1,534; lead, $2,940. Total, $14,965. Miami: Blende, $5,265; lead, $1,536. Total, $6,801. Alba-Neck City: Blende, $11,097; lead, $100. Total, $11,197. Spring City-Spurgeon: Blende, $3,610; calamine, $576; lead, $1,600. Total, $5,786. Carthage:: Blende, $3,720. Badger-Peacock: Blende, $5,148. Greenfield: Calamine, $385. Carl Junction: Blende, $1,600. Sarcoxie: Blende, $2,535. Cave Springs: Blende, $1,560. Stotts City: Blende, $1,216. Summary for the district: Blende, 9,575,750 lb.; calamine, 835,650 lb.; lead, 1,253,070 lb. Values: Blende, $183,500; calamine, $9,878; lead, $30,159. Total, $223,537. The surplus of zinc ore was cut from 9,259 tons to 8,881, but the lead ore surplus increased from 3,727 to 3,800 tons.

JULY COPPER REVIEW

By Misha E. Appelbaum*

The copper market up to almost the close of July was irregular and such sales as were made were on an average of 12½c. delivered thirty days, for electrolytic. Occasionally the price was shaded an ⅛ to ¼c. In the review for the month of June, I indicated that the key to the whole situation was curtailment of production, and that the producers had begun to realize this. It now seems that the leading producers have arranged to cut down production, and as a result during the last few days of the month copper advanced sharply with every indication that it will advance to a 13 or 13½c. I expect to see the market remain on that level for a few months, and as the surplus begins to decrease sharply, because of the curtailment, there should be further advances, although it is hoped that the advance will not be extreme, thus defeating the object of the move. Deliveries for the month of July are about 55,000,000 lb. for export and about 60,000,000 domestic, which would indicate a surplus of at least 10,000,000 lb. The mines, however, may have begun to curtail early this month and in that case the production would be less. For the first time in many years, the metal situation has been put on a sound basis. With improvement in business in the fall, the average price of copper should become satisfactory.

*President New York Metal Selling Company.

CURRENT PRICES FOR CHEMICALS

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

Crystalline, per lb	0.04	0.13
Gypsum, per ton	2.50	5.00
Infusorial earth, per ton	5.00	15.00
Magnesite, crude, per ton	5.00	7.50
Magnesite, dead calcined, per ton	22.50	27.50
Magnesite, brick (see firebrick).		
Manganese ore, oxide, crude, per ton	10.00	25.00
Manganese, prepared, according to quality, per ton	45.00	125.00
Mica, according to size and quality, per lb	0.05	0.30
Molybdenite, 95% MoS_2, per ton	400.00	500.00
Monazite sand (5% thoria), per ton	150.00	200.00
Nickel metal, refined, per lb	0.45	0.60
Ochre, extra strength, levigated, per lb	0.02½	0.03½
Platinum, native, crude, per oz	20.00	25.00
Quicksilver, per flask (75 lb.)	45.00	48.00
Scheelite (see tungsten ore).		
Sulphur, crude, per ton	15.00	25.00
Talc, prepared, according to quality, per ton	20.00	50.00
Tin ore, per ton	250.00	400.00
Tungsten ore, 65%, per ton	475.00	525.00
Vanadium ore, 15%, per ton	120.00	150.00
Wolframite (see tungsten ore).		
Zinc ore, 50% up, per ton	15.00	20.00
Zinc dust, 90% minimum, per 100 lb	8.50	9.50
Zinc oxide, per 100 lb	7.50	8.50

Dividends

The Bunker Hill & Sullivan Mining, Concentrating & Smelting Co. paid dividend No. 155 of $98,100 on August 5. This makes the total for the year $647,400, and to date $11,933,400.

Amalgamated Copper Co. has declared a dividend of 50c. per share, payable August 29 to stockholders of record July 30.

EDITORIAL

BUTTE men won the Ryan $1000 prize at Calumet, Michigan, July 30 by drilling 53½ inches in granite in 15 minutes. This sets up a new world's record for double-hand drilling, surpassing that of 48¼ inches made at El Paso, Texas, in 1904.

COBALT continues to furnish thrills in the way of discoveries of rich ore. The Temiskaming & Hudson Bay mine, which incidentally has paid 16,600 per cent on the investment, has produced the latest sensation in a 10-inch body of ore assaying 6000 ounces per ton, found 100 feet below the surface. Such masses of silver are especially welcome to the owners now that the price has improved.

ARRANGEMENTS are being made by Los Angeles members of the Mining and Metallurgical Society of America, for a society dinner, September 28, at the time of the meeting of the American Mining Congress. Possibly also a short field trip will be planned. Mr. Seeley W. Mudd has the matter in hand and visiting members may feel assured of an excellent time. All members of the society are requested to reserve the date.

FIRE has made another visit to the offices of the Geological Survey at Washington, but the firemen are becoming so expert in fighting flames in that particular building that little damage was done. We sincerely hope there may be no further delay in providing proper quarters for the maps and records now constantly in danger. Their destruction would entail widespread loss and we trust that this winter Mr. James R. Mann will restrain his customary propensity to object when the matter comes before Congress.

ILLINOIS is the first State to take up the mine-rescue work for itself. The matter has been placed by the Governor in charge of a commission consisting of Messrs. J. W. Miller and J. L. Schmidgall representing the operators, Charles Bennett and Charles Krallman, of the miners, Hector McAllister, inspector, H. H. Stoek of the University, and J. A. Holmes of the U. S. Bureau of Mines. It has been decided to spend $30,000 on three station buildings, $42,800 on equipment and maintenance, and to reserve $7200 for contingencies. Arrangements will probably be made also to equip railway cars with apparatus for demonstration and regular rescue work, and to keep them ready for instant service. Such close co-operation as is indicated by the make up of this commission, appointed in the midst of acute labor troubles, is striking, but this is only another of the many evidences that a dispute as to wages concerns economies and is not a personal matter.

MAIL service in Alaska is far from perfect. In the winter months deliveries of second-class matter to interior points are so slow and uncertain that there are frequent complaints. Copies of the *Mining and Scientific Press* for November 6 reached Nome, January 16, and those dated November 13 arrived June 5. Up to June 24, after steamers began to arrive, the numbers for February 19, March 5, and March 12, had not arrived though later numbers were at hand. This sort of service is inexcusable. Alaska deserves better treatment at the hands of Washington authorities.

DESIGNING a complete mine plant is not easy and any set of plans is subject to criticism. We take pleasure none the less in presenting the first part of a thesis covering plans for a plant to meet conditions that are not uncommon. The study illustrates the method of attack and also the sort of knowledge required of graduates at the Colorado School of Mines. We trust that the authors, Mr. J. W. Whitehurst and Mr. W. P. Cary may live to design and operate even larger and more complex plants than the one they have worked out as students.

OUR London contemporary, *The Mining Magazine*, has been usurping imperial powers in sending Mr. Ross B. Hoffmann to Siberia with Mr. J. P. Hutchins. In the past many men have been sent unwilling to the Siberian mines, but Mr. Hoffmann protests that he has not gone and has no intention of going. That mistakes in such matters will happen we are reminded by having inadvertently announced that Mr. Donald Foster is metallurgist for the Torres Mine, Ltd., Cherokee, Mexico. Mr. A. W. Allen is metallurgist for the Cherokee Goldfields, Ltd., at San Julian, Mexico, and Mr. Foster is his assistant. It is but fair to add that Mr. Foster was in no way responsible for the error.

THE FIFTEENTH annual meeting of the Lake Superior Mining Institute will include sessions at Ironwood, Michigan, August 24, at Chicago, Illinois, the 25th, and at Gary, Indiana, on the 26th. Thus the members will follow the ore of the Gogebic range from the mine to the steel billet, incidentally, we observe, pausing long enough to see the 'Cubs' contest with the 'Giants' at the National League ball park in Chicago. The field meetings of the Lake Superior Institute have an excellent and well-deserved reputation. They bring the engineers together and have done much to promote the personal and professional friendly feeling which obtains about Lake Superior and which makes that district more like the Rand than are many others in America.

SHASTA county, California, is feeling the effect of the enforced closing of the copper smelters. Many men are out of work, train service on the branch railway lines is disorganized, and the small gold mines that furnished quartz to the smelters are closing. Operations at the limestone quarries are suspended and indeed there is little activity except at the smelters, where work on new installations is being rushed. At Coram it is expected that the new precipitating plant will be ready to operate October 1. At Kennett the third furnace of the Mammoth Copper Mining Company has been connected with the bag-house with excellent results. The dust contains a high percentage of zinc oxide and zinc sulphate, but is readily handled. It is to be briquetted and returned to the blast-furnace.

Mining Bureau Work in Metal Mines

Members of the San Francisco Section of the Mining and Metallurgical Society of America have been particularly interested in the establishment of the Bureau of Mines at Washington. At the recent meeting at Grass Valley, the problems which the new Bureau might properly investigate came up for discussion. It was at once apparent that more were waiting than the most active corps of engineers could hope to solve in many years. In view of the large interest that Western men have in the work of the Bureau it was thought proper to attempt to reach some concensus of opinion as to the most pressing problems of metal mining and metallurgy. It is thought that a few well chosen recommendations will be welcomed by the officers of the Bureau and that Congress will be glad to appropriate funds for any reasonable amount of work of real importance and probable usefulness. Accordingly a committee was appointed to compile suggestions and submit them for discussion at the next meeting of the Section. Suggestions from engineers and others will be welcomed and may be addressed to the local secretary, Mr. H. Foster Bain in care of the *Mining and Scientific Press*. The work of the Bureau this year is, as already announced, to be concerned mainly with the problems of coal mining. Metal mines, however, have their own dangers and losses and are as worthy of aid. However willing the Acting Director, Mr. George Otis Smith, and his assistants may be, they cannot act except as Congress appropriates money and if Western men really have problems properly falling within the field of the Bureau, a matter about which the East seems in some doubt, they should make their influence felt. In the meantime we understand that the general investigation of the causes of mine accidents is to be broadened so as to cover metal as well as coal mines, and is to be under the immediate direction of Mr. George S. Rice, a thoroughly competent engineer whose assignment to this important work should remove all doubt as to the character of the men who will be employed.

Possibilities of the Rand

There has been in many quarters an impression that the output of the Rand in the Transvaal had about reached its maximum and that the total quantity of ore available was fairly well known. Some ten years ago Mr. John Hays Hammond, in an address made at Harvard University, estimated the remaining life of the mines at approximately thirty years and the total gross output at three billion dollars. Since then the number of stamps dropping has greatly increased. At the close of last year 9545 were in commission and more building. By increasing the weight and by adding tube-mills, the output per

stamp has been increased, and it would seem that serious depletion of reserves should begin to show. Instead, the large companies continue to report increased reserves and the June output is estimated at 640,000 ounces, the largest monthly return yet made. The annual production is now above $150,000,000, all without signs of exhaustion. Indeed, Mr. Lionel Phillips, director for the Rand Mines Limited, in an address recently delivered at Johannesburg, indicates that present production marks but a fair beginning rather than a climax. It is thought that the number of stamps is like to be doubled in the next decade. Improvements in mining and milling have offset decrease in value of the ore and higher labor costs, and Mr. Phillips sees no immediate limitation of output. Indeed, he estimates the lease of life for the Rand as likely to extend through the century, and the potential production at ten billion dollars. To win this vast amount of gold will involve working at depths of 7000 feet and handling immense quantities of rock. It is perhaps significant that just at present an increasing number of engineers are drawn to the district whose experience has been largely in coal mining. The future Rand mine will resemble a colliery more than the old type of metal mine. Ventilation will become of primary import and economical handling of quantities of material will be the main consideration. On these two points the colliery engineers can give valuable pointers to metal miners, and the 'deep deeps' of the Rand need the best services of engineers from all fields.

Petroleum and the Navy

Why the Navy does not adopt oil for fuel is being frequently asked, especially in California. About six years ago the matter was fully investigated by a 'Liquid Fuel Board' which made many tests and an elaborate report. No particular mechanical or technical difficulties were found to stand in the way of the adoption of petrolum but, in the opinion of the officers investigating the matter, the difficulty of insuring an adequate supply was such as to make the change from coal then inadvisable. Since that time there has been a great increase in production not only in America but abroad. In the United States the great Midcontinental field has been developed and connected with the Gulf Coast by pipelines. In California there is an abundance of petroleum which can be delivered to the ships at rates much below the cost of equivalent coal. The Mexican fields have come into the market and Russian production is greater than ever. Some wells have been brought in, not far from Manila, in the Philippines, and the prospect for a large production seems good. If big pools be opened there, the last objection to the change would be removed since adequate supplies would be available on all the coasts where the Navy has much occasion to maintain fleets. There are many advantages, other than economy, resulting from the use of oil on board steamers. The quickness with which steam can be raised would seem to be especially important in naval work. The steamer *Harrard*, of the Metropolitan Steamship Company, would probably have been destroyed when it caught fire July 16, except for the fact that it is an oil burner. At the time of the alarum the boat was at dock and had no steam, but pressure was raised so quickly that only slight damage was done. Similar promptness might well save us a battleship at a critical time, and the whole problem demands reinvestigation. We understand it will be brought to the attention of the American Mining Congress at the Los Angeles meeting. Great Britain is said to be about to adopt oil for naval fuel, and there would be much less difficulty to be met in the case of the American than the English Navy.

Conservation and a Warning

In a clear and well reasoned editorial in the *Journal of Geology*, Mr. T. C. Chamberlin calls attention to a growing confusion of thought regarding certain phases of the conservation problem. "The protection of natural values against wastage," he says, "is one thing, the possession of these values is quite another. The best conservation may not be correlated with the best ownership. Ownership, desirable on other accounts, may be an obstacle to conservation, and ownership, otherwise undesirable, may be tributary to conservation. This is so because, in their fundamental nature, the problems of conservation and the problems of possession are distinct questions, each to be solved in its own way and on its own basis. They centre in separate fields. The conservation of natural resources centres in the scientific and the technical; the right of ownership and the most desirable distribution of ownership centre in the political and the sociological. The best conservation of the soil is not necessarily dependent on the most desirable partition of the land. All questions of the possession and distribution of values may be marshaled under extreme individuality, extreme monopoly, or some combination of individuals and corporations lying between these extremes, but all are alike political and sociological in nature and, however they may issue in practice, they leave the scientific and technical problems of conservation of natural resources to be solved on their own bases. And these solutions must be fundamentally much the same under any political or sociological system." He points out that the special responsibility of geologists in the work is with the scientific and technical problems of conservation rather than with matters of ownership, in regard to which their opinions are inexpert. He pays a deserved tribute to the long quiet work of the Geological Survey in the matter of conservation and appeals to his fellow workers for clearer thinking in regard to the matter. His words will carry great weight not only with geologists, but others, because of his standing as the leading geologist of the United States, and a man also well versed in public affairs. It is becoming increasingly evident that conservationists are not all in one camp and that much honest difference of opinion exists as to the proper procedure. The meeting of the Conservation Congress at St. Paul, Minnesota, in a few weeks will be watched with much interest and will probably prove of great significance as to future direction of the movement.

Mines in Republic District, Washington

By W. A. Scott

The mining district of Republic is about thirty miles south of the international boundary, and was at one time included in the Colville Indian reservation, in Ferry county, Washington.

The Republic Con. Gold M. & M. Co., organized in the State of Washington, but controlled by Montreal men, purchased the original Republic mine of Patrick Clark about ten years ago and spent a large sum of money on development and equipment. A crushing mill and cyanide plant of large capacity were erected, the construction and operation of the mill having been in the name of the Republic Cyanide & Power Co., a subsidiary of the other company. After a failure to operate profitably, both mine and mill were closed down and the property was practically abandoned. The title to the mine and its equipment passed two years ago to Ferry county by virtue of sale to satisfy a lien for delinquent taxes; the title to the mill-site, however, is still vested in the Republic Cyanide & Power Co., though the plant has been partly dismantled. An effort was made in 1909 by stockholders of the mining company to invalidate the tax deed to the mine and contiguous holdings, but it was unsuccessful. In 1908, after tax title had passed to the county, the mine was leased to the Republic Leasing Co., organized by a number of miners of the district, who soon transferred their lease to the New Republic Mines Co., which now has a lease and option to purchase extending to March, 1912. Prominent in this company are Frank B. Babcock, of Cheney; R. J. Howard, of Spokane; W. B. Parker, J. L. Harper, and others. Mr. Harper was manager for the company till November 13, 1909, and during the year or more that he was in charge the mine is said to have shipped to Tacoma a sufficient tonnage of ore to net the company about $100,000, some of which was spent in development and equipment. Dissensions among the stockholders arose, and suits were filed to settle their troubles. One result was that Mr. Harper ceased to be manager, and Mr. Howard took charge last November. Just now little is being done except to keep four men at work on the property in order to hold the lease. The mine is opened by a 2250-ft. cross-cut adit driven to the orebody. From the intersection of the adit a drift was driven 350 ft. south on the vein and 90 ft. north, and above this level a great deal of stoping has been done.

Part of Surprise Mine, Republic, Washington.

In the meantime the Pacific Ore Co. has been organized by J. L. Harper, Robert Mabray, L. W. Anderson, E. R. Davidson, and others, all of whom are interested in the mines of Republic. The purpose is to operate a custom mill in the district which can profitably treat the ore too low grade to stand transportation and smelting charges. The construction of this mill is in progress. It involves crushing, pulverizing by Chilean mills, and cyaniding in agitating tanks, the Hess system of agitating and aerating having been adopted.

The Pearl Con. Mining Co., with Charles P. Robbins, of Spokane, as president, about eight months ago gave a bond on its Surprise, Pearl, and Lone Pine claims in Republic to the Republic Mines Corporation, for which J. L. Harper is general man-

ager. The price is said to be $225,000. The property lies on the east side of Eureka gulch, covering a portion of a north-south vein locally known as the Mother Lode. Work was begun here by Mr. Harper last January, and within six months from that time the Republic Mines Corporation has shipped 163 carloads of ore to Tacoma, aggregating 6814 tons, having a gross value of $47.31 per ton, and a net value of $36.64 per ton. The June shipments of 45 cars had a gross value of $112,000, and gave a net return of $93,000. July shipments will hardly come up to those for June. The railroad companies charge a minimum rate of $2.50 per ton from Republic to Tacoma, and a maximum of $4 on ore sampling $60 per ton or higher. The minimum treatment charge against Republic ores at Tacoma is $3.50 per ton. The shipper also gets 5c. per unit for all lime over 5%. Ore from the Pearl and Lone Pine workings carries 30% lime. It is understood that payments by Harper to the Pearl Con. Mining Co. have thus far amounted to $120,000, and that dividends to the amount of $25,000 have been paid to stockholders in the Republic Mines Corporation. The Surprise workings consist of an 80-ft. cross-cut adit to the vein, with 140 ft. of drift north on the vein and 450 ft. south; and a 40-ft. winze in ore from the main level. The Jim Clark cross-cut has been driven to the vein from the bed of the gulch, and 60 ft. lower than the principal level. These workings disclose an ore-shoot 600 ft. long and 8 ft. wide. All the ore between the porphyry walls is said to be shipped. The Lone Pine has 3000 ft. of the same vein, and has also a lateral vein. The principal development is at the intersection of the two lodes. While most of the ore shipments have been, so far, from the Surprise, the Pearl and Lone Pine are to begin shipping. An incline shaft is being sunk from the bed of the gulch, which is intended to cut the Surprise vein at about 500-ft. depth.

The Insurgent Leasing Co., controlled by E. J. Delbridge and Merrill Bros., has a lease on two fractional claims belonging to the Insurgent M. Co., principals in which are G. B. Dennis and others of Spokane. This ground adjoins the Lone Pine on the north and has the extension of the latter's east and west vein system. The Insurgent workings are now entered through the Lone Pine adit, which goes in 600 ft. and cuts the Insurgent ore at a depth of 180 ft. Most of the ore now being mined by the Insurgent lessees is taken from short drifts from an 80-ft. winze sunk from the principal level. Mining is done with power-drills driven by a Leyner compressor, and the hoisting is by steam power. Mr. Delbridge states that shipments are being made at the rate of 45 cars per month to the smelters at Grand Forks and Greenwood, B. C., the ore averaging $17 per ton. It contains 80% silica and is in demand at those plants for converter lining. The freight rates to those places are $1 per ton on $15 ore, and $1.50 on ore running higher; the treatment charges are $5.25 to $7 per ton.

The Knob Hill group of two claims is situated close to where Eureka gulch forks and has the northern extension of the Lone Pine-Surprise lode. This belongs to the Jonathan Bourne interests, but it was recently taken under bond and lease by the Knob Hill M. Co., which is controlled by J. W. Lloyd and associates of Spokane. Work has commenced on a 180-ft. cross-cut which is expected to reach the vein at a depth of 264 ft. By raising on the vein from this cross-cut a connection will be made with the old workings. It is said the property has a 30-in. streak of ore which assays over $50 per ton. The wider portion of the vein carries low-grade but still profitable ore.

On the west side of Eureka gulch is the San Poil vein, parallel to the Surprise-Lone Pine vein, and 600 ft. distant. The San Poil, Ben Hur, Trade Dollar, North San Poil, and Bodie are the most important properties on the San Poil lode. The Ben Hur is in the hands of the Ben Hur Leasing Co., whose lease runs five years and seven months. Up to June 15, 1910, between 90 and 100 cars of ore had been shipped to Grand Forks and Greenwood, the grades having been from $10 to $30 per ton. Work ceased last month, and those in control have plans for milling their ore. The property is opened by a 790-ft. adit and a vertical shaft, the workings extending to a depth of 400 ft. A. B. Hurd, A. M. Kingston, and A. W. Frazer, of Grand Forks, and G. W. Fairweather, S. Ferguson, and James T. Johnson, of Republic, are the men comprising the leasing company.

Mother Lode on Surprise Claim, Republic, Washington.

The San Poil lode seems a promising one. Some work is being done on the other properties. Most of the mines and prospects of this part of the district are on or close to Eureka gulch, which drains southerly into San Poil river.

The Colville Mining & Smelting Co., H. J. Lyeett, manager, has 28 claims at Park City, 25 miles south of Republic, on which development is in progress, which has resulted in opening bodies of galena of good grade. This is controlled by Eastern people.

Design of a Mine Plant

By J. W. Whitehurst and W. P. Cary

Part I—Pumps and Surface Plant

*Problem.—The problem presented for solution was to design and lay out a plant and select machinery and equipment for a mine operated through a 1000-ft. vertical shaft. It is proposed to hoist 225 tons (75 tons of ore, 150 tons of waste) 12 hours per day, through a 3-compartment 4 by 4½-ft. shaft (2 hoisting, 1 manway). Practically all ore has been stoped above the sixth level and the output is to be taken from the seventh, eighth, ninth, and tenth levels, still to be opened. A sump 10 by 13 ft. is to be cut near the shaft on the 980-ft. level; a pump placed there is to deliver to the surface 100 gal. of water per minute under a total head of 1000 ft. Surface conditions have been assumed similar to those of the New Monarch mine, situated about six miles east of Leadville, Colorado, near the headwaters of Big Evans gulch. The altitude here is approximately 10,500 ft. above sea-level. This is a district of strong winds with severe winters and heavy snowfall, wherefore an allowance is made for a ten-day blockade in transportation. The excessive cost of fuel at the mine has favored an electrical installation; current to be purchased from an independent company. It is upon the foregoing conditions that all the calculations have been made and the design carried out.

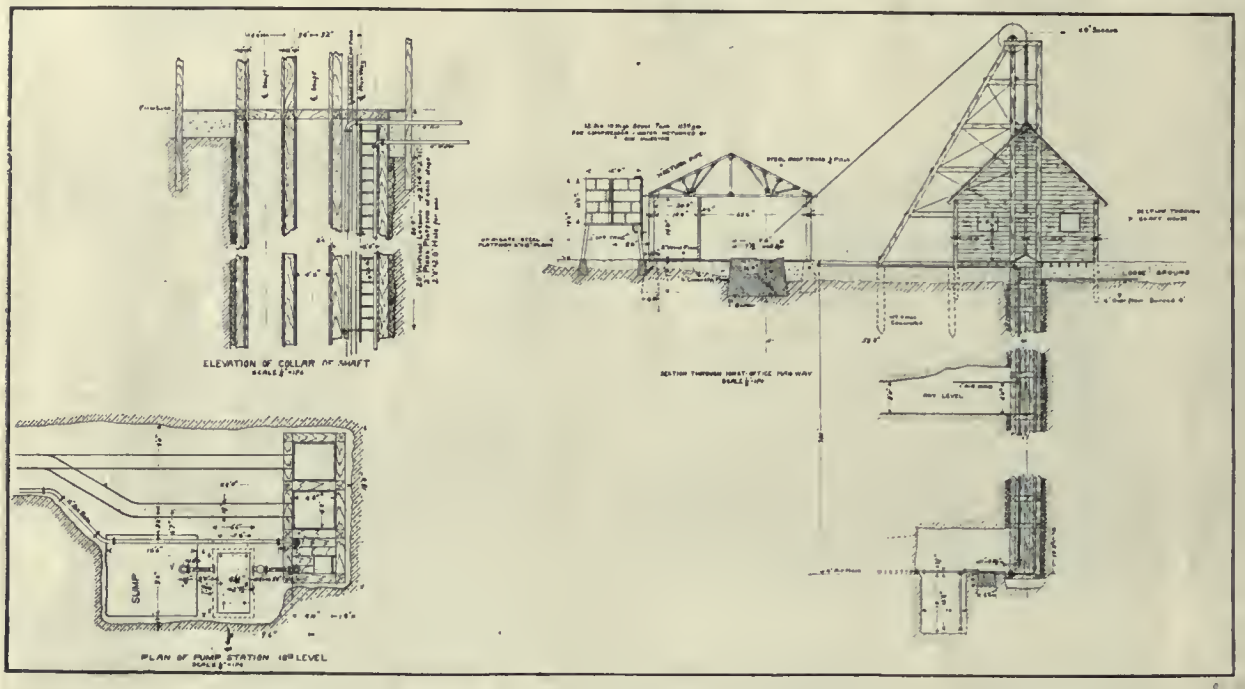

Fig. 1.

Pumping.—The tenth level is about the lowermost limit of the workable ore deposits, and therefore a sump is cut here, some little distance from the shaft (see Fig. 1). By so placing the sump, the pump can be piped to more advantage, diminishing the friction-head by eliminating sharp turns. An electrically-driven triplex pump capable of delivering 100 gal. per minute under a total head of 1000 ft. has been selected. Barometric pressure at this altitude is taken as 10 lb. per square inch, absolute, equivalent to 23.1 ft. of water. Practical suction lift = 80% of 23.1 ft. = 18.48 ft. from floor of tenth level; assumed suction lift = 12.6 ft.; lift from pump-floor to surface = 976 ft.; assume a 4-in. discharge pipe; then velocity of water = $\frac{134}{\frac{\pi}{4} \times \frac{1}{9}}$ = 153.5 ft. per minute. Pipe friction at this velocity and size of pipe = 0.9 ft. of water per 100-ft. length of pipe, and for 1000 ft. of pipe = 9 ft. Total lift = 997.6 ft. Assume this to be 1000 ft. for all practical purposes.

Horse-power in-put to pump = $\frac{100 \times 8.33 \times 1000}{33{,}000 \times 0.8}$ = 31.6

where 80% = combined efficiency of pump and motor; assume, as above, a triplex single-acting pump at 100-ft. piston speed per minute: one cylinder will have to handle $\frac{100}{3}$ = 33⅓ gal. of water per minute; 33⅓ gal. = 4.45 cu. ft. of water per minute: allow 10% for leakage past valves and plunger: displacement = $\frac{4.45}{0.9}$ = 4.95 cu. ft. per minute. Let r and d equal respectively the radius and diameter of plunger in inches, then $\pi r^2 \times 50 = 4.95$: $r = 0.1773$ ft.; $d = 4.25$ in. diameter of plunger: let the stroke be 7 in.; therefore select a 4 by 7-in. triplex single-acting pump. Under 100 gal. per minute at 1000-ft. head, a 4 by 7-in. pump requires a 35-hp. A. C. motor at 760 r.p.m. The pump is to be run at 88 r.p.m. Allowing 5% for line and transformer losses, this motor will require 36.8 hp. at the switchboard. The pump selected is illustrated in Fig. 2. The figures used are taken as the general averages in good use by designers of pumps.

The suction pipe of the pump is to be fitted with a plain cone-shaped strainer and to be of light-weight iron, 5 in. diam. The lower 500 ft. of discharge pipe to be of 4-in. special extra-heavy hydraulic flanged-

**Mining and Scientific Press* prize thesis, presented as part fulfilment of the requirements for graduation at the Colorado School of Mines, June 1910.

pipe; the next 225 ft. should be of medium weight; the upper 225 ft. to be of light weight flanged-pipe; the pipe from shaft to overflow to be of ordinary screw-joint, light weight, iron pipe. The pipe is to be brought down the manway (see Fig. 1) and to be tied to spreaders at every 5-ft. section. At the tenth level the pipe is to be carefully braced with a 12 by 12-in. block, and tied to timbers. The discharge at top is to be taken out of the shaft 4 ft. below the surface and run to some distance from the shaft. The water is useless, as it is muddy and slightly alkaline. Power is to be delivered to the motor at 440 volts, 60 cycles, 3 phase, through rubber-covered cables enclosed in a lead sheath, cable taken down manway and tied to timbers at each set.

Compressing.—It is proposed to use compressed air for drilling during a period of 16 hours, during two 8-hr. shifts; loading and shooting to be done during the remaining shift. Assuming that a 2¼-in. piston drill will break 10 tons of rock in an 8-hr. shift, it is found that the approximate number of drills required will be as follows: Rock to be broken per 16 hours = 225 tons; capacity of one 2¼-in. drill for 16 hours = 20 tons; number of 2¼-in. drills necessary, 11.25. These drills are to break all the rock to be hoisted in the mine; the waste broken by drills doing development to be used to fill open stopes. The 2¼-in. drills are equivalent to 68% of 3-in. drills, and hammer-drills to 36% of 3-in. drills. These two constants are based on the relative air consumption of the drills. The drills cannot be operated continuously, due to loss of time in setting up and changing steel. Hammer-drills require scarcely any time to set up and change steel, and therefore this consideration is not necessary. With the equivalent of a total of 8.3 three-inch drills in operation at one time, each requiring 125 cu. ft. of free air per minute at a pressure of 90 lb., a total of 1038 cu. ft. of free air (62°F. and 14.75 lb. pressure per square inch) is required at the drills; the operating pressure at the drills to be 90 lb. per square inch gauge.

The barometer at the mine reads approximately 20.39 in., equivalent to 10 lb. per square inch absolute pressure. This may be corrected for altitude as follows:

$$\frac{pv}{T} = \frac{p_1 v_1}{T_1}$$

where $T = T_1$ = average absolute temperature of air at the mine.
v = volume at sea-level.
v_1 = volume at mine.

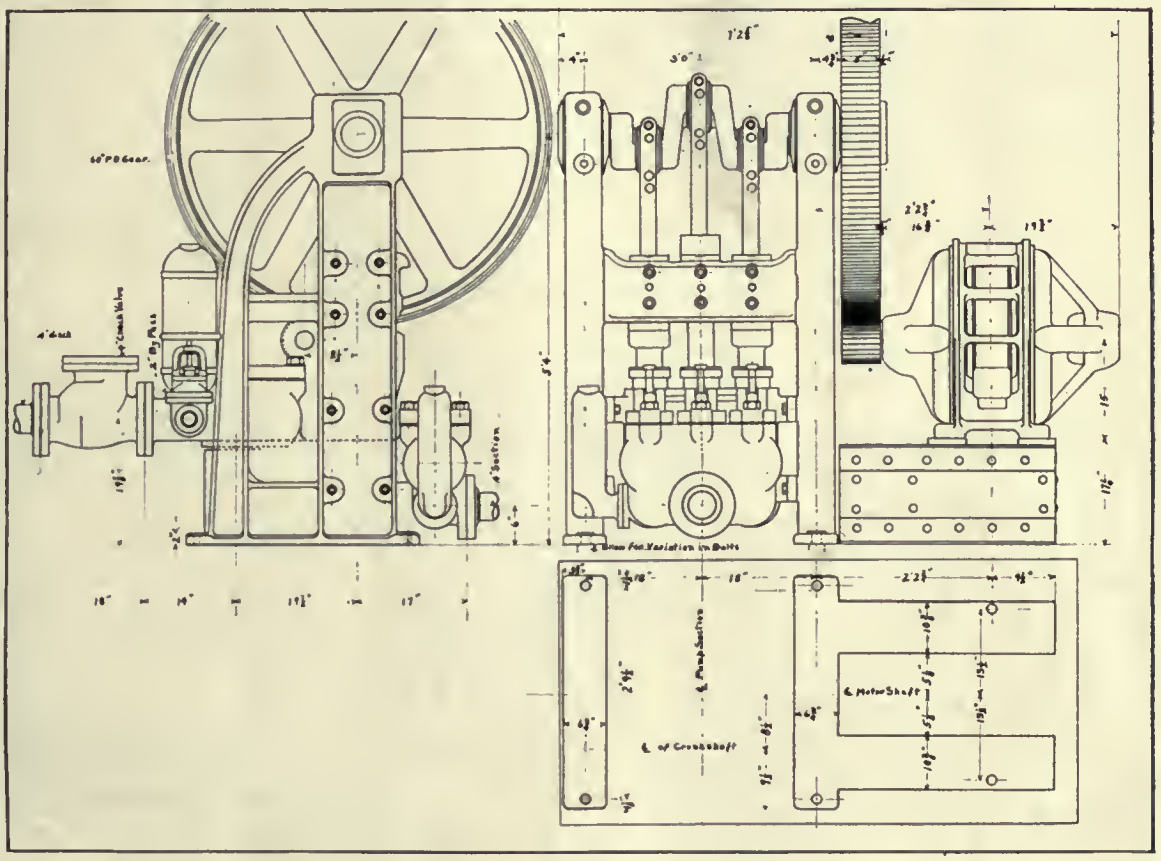

Fig. 2.

p = 14.75 lb. absolute.
p_1 = 10 lb. absolute.

$$v_1 = \frac{pv}{p_1} = \frac{14.75 \times 1038}{10} = 1525 \text{ cu. ft.}$$

To estimate the air required, allow 10% loss in transmission of air through pipes, then there will be required: $\frac{1525}{90} = 1698$ cu. ft. under atmospheric conditions at discharge valves of compressor. Allowing a loss of 5% for imperfect valve action and heating of incoming air, there will be required taken into the compressor per minute $\frac{1698}{95} = 1785$ cu. ft. under atmospheric conditions. To allow for loss of pressure in transmission it is considered that the final discharge pressure at the compressor is 95 lb. gauge. It is better therefore to select a two-stage machine. The absolute discharge pressure of the low-pressure cylinder will be: $p' = p_1 p_2 = 10 \times 105 = 32.4$ lb. absolute, where p_1 = atmospheric pressure absolute,

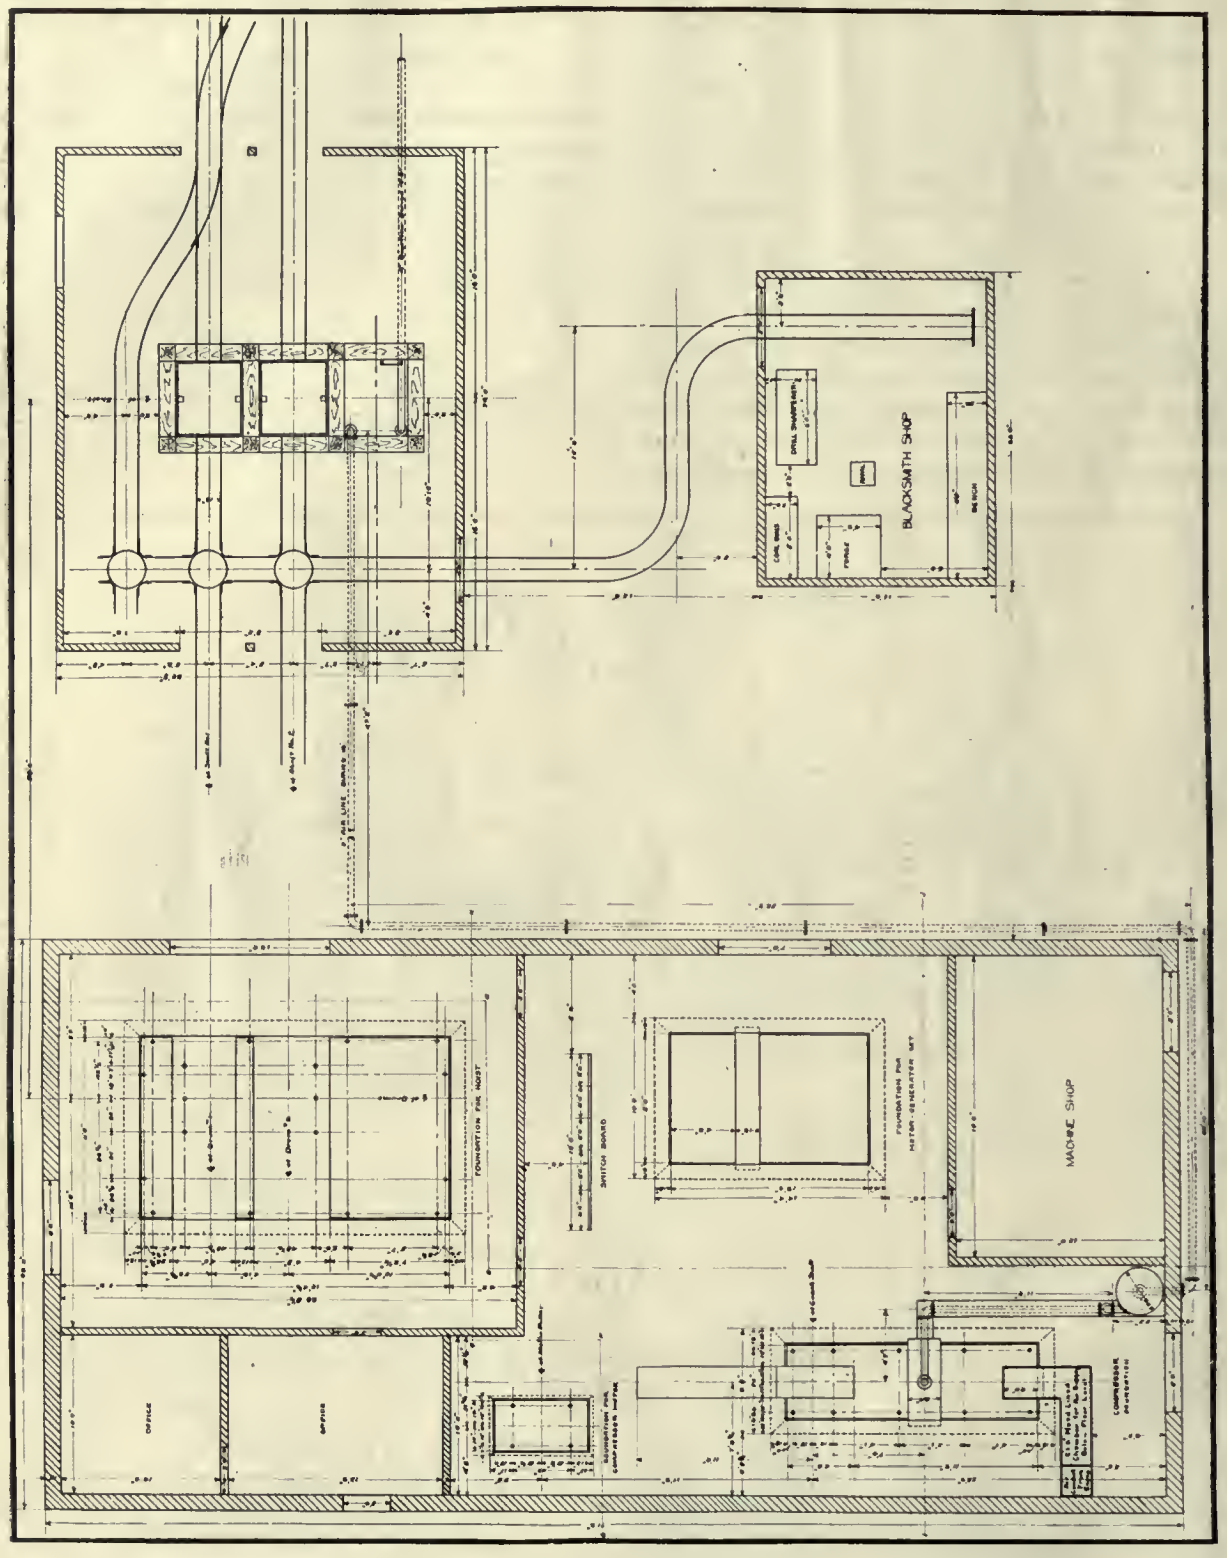

Fig. 3.

p_2 = final compressor pressure absolute. The assumption of complete cooling between stages and equal distribution of the work is made in above formula.

Assuming 2% clearance, the factor of clearance becomes,

$$F = 1 - \frac{2}{100}\left(\frac{32.2}{10}\right)^{0.712} + 0.02 = 0.974$$

The factor of clearance is equivalent to the ratio of the displacement of the piston to the total value of the cylinder. Then the displacement of the low-pressure cylinder is:

$$\frac{1785}{0.974} = 1832 \text{ cu. ft. per minute.}$$

Assume a 24-in. stroke with the compressor running at 150 r.p.m. Then the displacement per stroke of low-pressure cylinder is:

$$\frac{1832}{2 \times 150} = 6.106 \text{ cu. ft.}$$

and $\frac{6.106}{2} = 3.053$ sq. ft. = area low pressure cylinder. Diameter of low-pressure cylinder, approximately 24 in., and 13.4 in. diam. of high-pressure cylinder; indicated horse-power of air cylinders is 218. Allowing 77% for combined efficiency of motor and compressor,

$$\frac{218}{77} = 283 \text{ hp. required for motor.}$$

From the above data a belt-driven 2-stage compressor has been selected. The compressor is to be driven by a 440-volt, 60-cycle, 3-phase, 285-hp. in-

duction motor running at 600 r.p.m. with a driving pulley 30 in. diam. The belt is to be extra heavy double-ply leather, 21 in. wide. This compressor is rated at 1885 cu. ft. free air per minute at 95-lb. gauge pressure, which corresponds closely with calculations.

The compressor is to be equipped with an unloading mechanism, especially applicable to motor-driven compressors, being completely unloaded at any radical change in speed. This allows the motor to come up to normal speed under no load. The control is operated by a centrifugal governor affected by speed alone. In conjunction with this there is a set of valves, called the 'air control,' operated by the air-pressure of the receiver, which open or close the inlet valves in accordance with the demand for the air. Air should be supplied to the low-pressure cylinder at as low a temperature as possible to secure greatest efficiency. There is an increase in volumetric efficiency of 1% for every 5°F. reduction in temperature of entering air, below that of the engine room. To accomplish this, a wood conduit 2 by 2 ft. is led from the inlet valves of the compressor to a point under the eaves on the north side of the building, as shown in Fig. 3. Receivers are not so much for the purpose of storing the air, thus acting as a reservoir of energy, as to partly cool the air and free it from moisture before entering the main pipe-line, and to reduce the pulsating effect produced by the operation of the compressor. With these objects in view a 36-in. by 8-ft. upright receiver is to be erected as shown in Fig. 3. A second 30-in. by 5-ft. receiver is to be placed at the seventh level station to supply the seventh and eighth levels by means of suitable and separate 2-in. pipe-lines. A third 30-in. by 5-ft. receiver is to be placed near the pump station on the tenth level, supplying the ninth and tenth levels through 2-in. pipe-lines. The pipe, from compressor to receiver, is placed in a conduit, one foot square, in the cement floor; the floor at top of the conduit is recessed for receiving a cast-iron cover. From receiver to shaft the pipe is buried 18 in. underground. In the shaft the pipe is supported every 10 ft. From compressor to seventh level the pipe is 5 in. inside diameter; at this point a 4-in. branch line runs to the receiver and the main line, reduced to 4 in., extends to receiver on tenth level. All piping is to be standard weight, lap-welded mild steel, with flanges screwed on and supplied with suitable rubber gaskets.

Lighting and Shops.—The lighting of the plant and mine is to be done with 56-watt incandescent and 495-watt arc lights. A small transformer is used in connection with surface lights. The underground lighting, at stations only, is accomplished with incandescents. The current for station lighting is to be taken below in the cable for the pump motor and tapped off at each of the lower four levels, where a small line transformer will reduce the voltage to 110. Wires in buildings to be enclosed in ½-in., light-weight, galvanized iron pipe. All wires are to be rubber covered and joints carefully insulated. These lamps will require power as follows: 138 lamps, 56-watt = 7736 watts, 11 lamps, 395-watt = 5445 watts, making a total of 13,181 watts, or 13.18 kw. required by lamps at point of consumption. Allowing 5% for line loss = 13.87 kw. required at switchboard, and $13.87 \times 1.34 = 18.59$ hp. required at switchboard.

Shops.—The blacksmith shop is to be equipped with a 110-volt, A. C., 5-hp. motor for operating drill-sharpener and forge-blower. This shop is to be built of brick (see Fig. 3), roof to be of corrugated iron on light steel frame. The foundations are to be of masonry and to extend 2 ft. 6 in. below surface; floor to be either earth packed hard, or 4-in. concrete and cement. The machine shop (Fig. 3) is to be equipped with a small lathe and drill-press operated by a 7.5-hp., 110-volt, A. C. motor.

Ore-Bins.—The bins are to be placed on the side of the ridge so that ore can be run directly into the standard-gauge cars on the railroad, and to have a ten-days storage capacity, or 750 tons of ore, equivalent to 7500 cu. ft., assuming that a ton of broken ore occupies 10 cu. ft. The shape of the bins is to be that of a right-angle triangle, with one leg horizontal and the other vertical. The bins are to be made of two layers of 2 by 12-in. planks supported by 12 by 12-in. timbers. The house, or covering, is to be of 1 by 12-in. boards with sloping shingled roof. The eaves to be 8 ft. above the feed track. The uprights and supports for the house are to be of 6 by 6-in. timbers securely imbedded in concrete piers. All upright timbers are to be securely imbedded in concrete piers. The roof is to slope at approximately 45°, on account of the heavy snowfall. The bins are to be discharged by steel doors operated from the outside. This building is to be lighted and equipped with eight windows, three on a side and one at each end. The ore-house door is to be made of sliding construction, 7 ft. wide by 7 ft. high.

Fire Protection.—The plant is to be equipped with 25 fire extinguishers, these to be distributed in the buildings and on the four lower levels of the mine. The water-tank for the compressor is to be attached to an air-injector and garden hose for emergencies. The column-pipe for the pump discharge is to have a nozzle attached at each of the levels of the mine for fire protection at the stations. The shaft-house is to be equipped with not less than three axes and three saws, to be used only in case of fire.

(To Be Continued.)

Old timbers should not be left in a mine when they can be removed. It is cheaper in the end to remove them to the surface where they may be dried and burned. If left in the mine sound timber may be infected from the old, and decay results in the formation of carbon dioxide which contaminates the air and also throws out heat. Many old abandoned stopes give practical evidence of this.

Dividing the bin beneath the station at a mine shaft into two compartments, one for waste and the other for ore, is ordinarily easy. It simply requires the secure placing of a few stout timbers to which planks can be firmly spiked. Where space is available this is a ready means of handling both waste and ore.

Concentration of Slime—II

By Edwin A. Sperry

(Continued From Page 177)

It is interesting to note some of the results accomplished by the use of the Callow screen, in actual mill work, as given by Mr. Callow. In one case, two screens 4 ft. by 24 in. were installed, screening to 40 and 100-mesh, respectively. The first screen (40 mesh) takes the undersize from a 6-mesh, 22 wire (0.137 in. or 3.5-mm. open space) trommel, and handles 150 tons per 24 hours, or 6.25 tons per inch of belt width. The life of the belt in this case is 35 days. The second screen (100-mesh) handles the undersize from the first screen, amounting to about 30 tons in 24 hours. The life of this belt is upward of three months. The oversize from the first screen goes to two jigs. Formerly three jigs were used to handle this product. The oversize from the 100-mesh goes to one Wilfley table, where four tables were formerly used, and the undersize from the 100-mesh goes to four Wilfley tables. The muddy water from these last Wilfley tables is settled, dewatered, and treated on vanners. The final results show a great reduction in value of the tailing. The jig tailing is reduced from 0.6 to 0.3%, and the Wilfley tailing from 1.3 to 0.35%. Several similar cases might be cited. This improvement in results is probably largely due to the increased thoroughness of the sizing and may be cited as a practical illustration of its great importance. The cleanness of the work has been shown in tests which have come to my notice, one being on an ore especially difficult to screen, which showed less than 4% of undersize remaining on the screen. In that the pulp is quiescent on the screen, the production of slime is slight in comparison with any screen in which agitation, shaking, or rolling is employed.

The action of the King screen is similar to the Callow, with the exception that a slight rolling motion is given to the ore. In cross-section it is hexagonal, the sides being curved opposite the circumscribing circle. A spray pipe is placed directly over the centre of the screen, on the outside, the purpose of which is to wash the pulp as it passes beneath it. The undersize material passes through the screen into its proper launder, while the oversize is discharged over the edge into its hopper. There are sprays placed inside the screen below its centre which clean the screen of particles which may be lodged in the meshes. The slight rolling motion given the pulp seems to aid in the washing action without material injury to the screen. In one instance this screen was in constant operation for over four months without appreciable wear to the screen cloth. In this case, 100-mesh screen cloth was used on 30-mesh pulp, there being less than 4% of undersize remaining in the oversize. The same advantage in the matter of reduction of slime may be credited to the King screen as to the Callow, though in less degree, owing to the slight rolling motion already mentioned, but this can hardly be considered as material, as the action is slight, both in amplitude and time. The life of the screen appears to be somewhat longer than that of the Callow, the reason for which is probably in the fact that it is not subject to a continued bending as is the case in the Callow. The rolling action in the King may, however, offset this when comparisons are made in long continued operation. The capacities and efficiencies of the two forms seem to be nearly identical, and while the King screen has some advantage in the matter of weight and floor space, the Callow requires less height, which in some cases is of importance. In comparative work between the King screen and the trommel, and extending through several months, the proportion of slime produced in one mill, separating lead and zinc, was 20% for the trommels as against 12% for the King. These results were probably due, in part, at least, to the prompt and thorough isolation of the undersize by which only a slight proportion was returned to the crushing machines. It can be stated certainly, that in the development of this type of screen, as exemplified in both the Callow and King, a great advance has been made in the solution of the problem of sizing as regards 'fine' and 'slime' work, and several forms based on similar action have been recently introduced with satisfactory results.

CLASSIFICATION

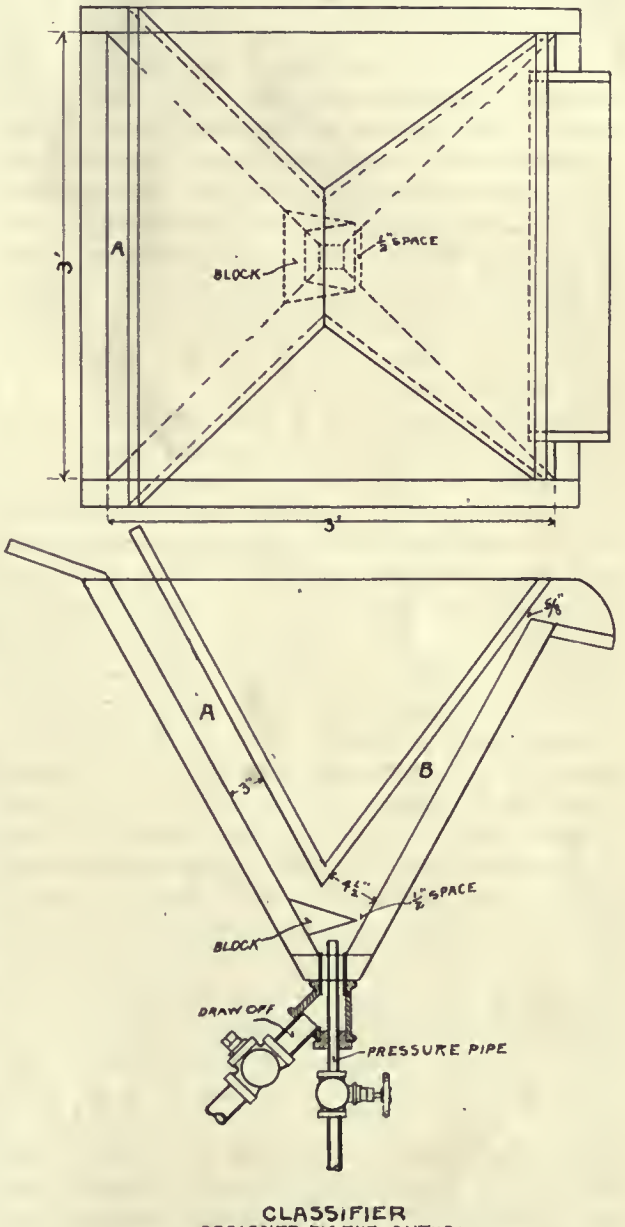
Classification is sometimes confused with sizing, but they are based on diametrically opposite principles. A few comparisons will serve to more definitely fix the difference in mind. As previously stated sizing is the separation of ore particles into classes having the same diameter, within a certain range, regardless of their specific gravity. Classification is just reversed—it is the separation of ore particles into classes having the same settling velocity in water, within certain limits, regardless of their diameter. It is based entirely on the speed of settling which is directly influenced by specific gravity. An extended discussion on the sizes of equal-settling particles will not be attempted, but it will be sufficient to mention one comparison—quartz and galena. A particle of galena has about the same settling velocity as a particle of quartz approximately four times its size. From this it will be seen that there is a wide variation in the sizes that would be drawn off together. In concentration sizing is of great importance and without it the treatment of the ore is rendered most difficult. As a result of classification the ore particles show extremely wide variations in the matter of size, as has been shown, far exceeding the range of sizes which, it would seem reasonable to believe, would give the best results. There is much discussion on this point, with honest advocates on both sides. One point held is that, as the quartz particle is so much larger than the galena, it extends farther up into the flow of water and is more readily rolled. If the action of carrying off the quartz particles were that of rolling this might be considered important, but as the ore is stratified before any elimination of quartz takes place, the latter must necessarily rest on the stratum of metallic particles. If, then, the quartz particle is rolled it is more than apt (and, in fact, this condi-

tion has been met and noted) to cut a channel in the mineral stratum and by thus disturbing it afford the mineral an opportunity to pass off with the quartz. As a matter of fact, the quartz particles should move off as a body, gently, and in passing over the mineral, should not have sufficient weight to disturb the mineral stratum.

These arguments refer entirely to sizes larger than 100-mesh, 38 wire material, as the use of classification on sizes finer than this is not often advantageous. In these sizes the above objections cease to be serious. This is due to the fact that when these extremely small sizes are reached, the behavior of all the particles, either quartz or mineral, is similar. This is one of the reasons why the treatment of slime is difficult. While it has been stated as a fundamental fact that hydraulic-classification is theoretically imperfect, still it must be conceded that, beyond a certain point, the ability to size by screen is impracticable if not impossible. From this point, taken for the sake of argument at 100-mesh, 38 wire and finer, the practice must of necessity be hydraulic classification. As to the form of the appliance best fitted to do this work there is room for discussion. In the use of hydraulic classifiers in the form of the 'cone sizer,' as it is termed, there is ordinarily excessive use of wash water. In this addition of water two serious results are brought about, one being the extra demand for water, and the other, the dilution of the pulp to such an extent as to cause trouble in its subsequent preparation for final treatment. In some cases the dilution of the pulp has extended to a 4% solid consistence. Now, when it is taken into consideration that slime pulp should be delivered to the table for final treatment at not less than 15% solid consistence, for some classes of machines, and as high as 25 or 30% for others, it can be readily seen how serious dilution may become. It has been stated, and is still maintained, that in some cases, sizing to 100-mesh is considered close enough in practical operations. There are cases, however, where there is a great advantage in isolating material which more nearly approaches the condition of slime, as indicated in the second definition given. One case which can be cited is that of a tailing which was being treated for the extraction of lead in an extremely fine state. It was found by experiment that practically all the recoverable mineral was extracted from material coarser than 200-mesh, 45 wire, and in order to obtain the best results the minus 200-mesh had to be isolated. For several reasons it would have been futile, if not disastrous, to attempt to make this separation by the use of the ordinary cone classifier. The additional water would have been prohibitive of good results in the final treatment, and it would have been impossible to divert a portion of the fine mineral particles into their proper channel as well as was done by the method employed.

Many forms of classifiers have been devised which, in most instances, can be placed in one of four types: (1) the cone-sizer; (2) the spitzkasten; (3) the spitzlutte; (4) the sizing-launder. In some cases it might be hard to typify a machine in which a combination of the several types is employed. There are two general methods of applying the principles on which hydraulic classification is based, one being by the use of a rising and the other by means of a horizontal current.

The first type, the cone-sizer, using a rising current and clear water jet, while being the one most commonly employed, has, in my judgment, the least to recommend it. The quantity of water necessary



CLASSIFIER
DESIGNED BY THE AUTHOR

Fig. 1.

for its operation is excessive, adding materially to that already in the slime, which certainly should be avoided, while the liability of choking is great, and necessitates constant watching. A simple form of classifier is shown in the accompanying cut, Fig. 1. This classifier was designed to remove the muddy water from material being fed to a 10-mesh jig. The main idea was to change the flow from a rapidly increasing downward current to a uniform up-current, and at the same time to pass by, rather than to feed toward, the aperture leading to the draw-off. In this way the up-current would not have to overcome the down motion of the particle, and if its specific gravity were sufficient, it would overcome the rising current naturally and of its own weight.

As the pulp passes down at A, it increases its speed as it approaches the lower point of the classifier, and as it strikes the 'block' shown, it is deflected quickly into the channel, B, which is so designed that it has a uniform sectional area at all points along its entire length. As the pulp passes through the constricted area immediately above the 'block' it is thrown up into the uniform current for some distance, and if the speed of the current is not rapid enough to carry it along to the discharge it will fall onto the lower wall of the channel, B, and pass down through the ½-in. slot between the 'block' and this wall, into the discharging chamber below. In the meantime the water from the pressure pipe impinges on the bottom of the 'block,' and distributing, passes up quite uniformly through the ½-in. space and washes the muddy water from the draw-off material. It was found that by its use classification was excellent and the feed on the jig was clean. It is certainly cheap and simple, and a carpenter can make one easily in a day.

The second type, using a horizontal current, has much to recommend it. This type, as stated, is exemplified in the spitzkasten. In this form, not only is the excessive use of water avoided, but much clear water is recovered, thus increasing the available water supply. Again, the pulp as drawn off is properly prepared for treatment on the various machines designed for treating the different sizes, especially the slime. It cannot be denied that there is a tendency toward choking, but as the depth of water in the spitzkasten is greater than in the cone-sizer, this can be more readily avoided. It can also be done by attaching a pressure or service pipe to the draw-off spout. By turning it on when necessary the clog can be broken. This pressure pipe is not so readily applied to the cone-sizer, as it is already employed in its regular operation. In one instance in my experience, which will be dealt with in detail under the head of 'Dewatering,' the classification in a spitzkasten, 8 by 10 by 30 ft., was almost perfectly done, grading regularly down in each of the four compartments, from 60-mesh in the first to 200-mesh in the last.

The third type, the spitzlutte, is made in the form of a V-shaped trough with the course of the flow transversely. A similarly-shaped, vertically-sliding trough is inserted in such a manner as to form an oblong channel bent at the middle. The sectional area of the channel is uniform at all points. This gives a down and an up flow at practically the same speed, the clear-water jet at the apex, compensating for the draw-off of the coarse material.

In the sizing-launder there is a resemblance to the spitzkasten much reduced in size. Several forms have come to my notice, some using enlarged sections with hoppers and clear-water jets, and some longitudinal slots in the bottom at intervals along its length. The simplest and most effective of those noted is the form constructed and used by Frank Bosco, in the Grand Mogul mill, at Gladstone, Colorado. Its normal form was in the shape of a V. At intervals the form was changed to that of a square-box launder for a distance of 2 ft. In this portion, a longitudinal slot was cut in the bottom along the centre line. The tendency of the coarse material was to collect at the apex of the V-shaped section, and as it debouched into the widened section this coarse material was delivered directly to the slot, and, passing down through it, was collected in a hopper attached to the launder and conveyed to its proper destination. Its operation and results were satisfactory.

DEWATERING

While proper sizing is certainly an important step in the preparation of slime for treatment, settling and dewatering has probably more influence on the final result than any other step in the process. This is more readily and easily accomplished by the use of properly shaped settling tanks, more especially the spitzkasten. This appliance is a V-shaped tank, ordinarily 24 or 30 ft. long, 8 ft. high, and 10 ft. wide, the sides being brought together at the bottom. It is generally divided into sections by the use of sloping divisions usually 3 ft. high, so built as to form hoppers at the bottom. These sections are 6 ft. long and have draw-off holes at the apices. The flow from them is regulated by inserting plugs having holes bored through the centre and attached to long rods to be manipulated from above the tank. A series of plugs having different sized holes is made so that by the proper selection, the draw off may be larger or smaller. A fuller description of the spitzkasten will be given later. There is one principle in the treatment of slime by concentration that is so often lost sight of by men who have been considered capable in their line. This is the matter of the absolute necessity of a thoroughly gentle method of coaxing, instead of a violent method of attempting to force, the particles to do the will of the operator. The slime particle is a wilful and elusive little fellow, and the old saying that 'you can catch more flies with sugar than with vinegar,' will certainly obtain in this case. It is better by far to let the particle seem to have his own way and then, after that way has been carefully studied and learned, to adopt such methods as will meet his wilfulness and set a trap for him into which he will naturally fall of his own accord.

The principle briefly stated is: in all operations connected with the handling of slime the utmost importance must be given to the avoidance of currents or agitation. The sooner this fundamental principle is fully understood and its full value appreciated, the sooner will the problem of the concentration of slime be simplified. This applies to all devices, as well as to the so-called improvements on otherwise efficient appliances in which, or by which, any kind of agitation, restriction of flow, disturbances, or currents of any kind are created. Among these can be classed the so-called 'baffle boards,' which are supposed to throw the particles down to the bottom of a settling device of any kind. Also, the form of spitzkasten which, being composed of a series of inverted pyramids, have the overflow from one to the other at or near the surface. Another is the 'over and under' settling tank containing partitions which are set alternately above and below through constricted sections.

There is another method of handling slime which I can freely say has little to recommend it. That is the use of the 'canvas plants.' I will assert, without fear of contravention, that, in comparison with the settling method, it is far inferior. In practical demonstrations, the saving of mineral has ranged from 40 to 50% for the canvas as against 60 to 80 for the settling method. This is borne out by actual test and experiment. In one particular case which came under my observation, there were 180 tons of ore crushed every 24 hours. Rolls were used. The mill tailing was screened on 20-mesh shaking screens. The undersize was further sized by the use of large settling tanks, the overflow from which was approximately 60 mesh or finer. This product amounted to 65 tons in 24 hours. Of this amount, 13.16 tons was caught on the canvas, and 51.84 tons was wasted. Taking lead as a basis of calculation, the average value of the 65 tons was 4.7%. The product from the canvas plant to be re-treated or cleaned was 20.2% of the total by weight, and averaged 12.1% Pb, containing 51.6% of the total lead. Of this lead 95% passed a 200-mesh screen, representing 49% of the total. The minus 200-mesh size of this product was 50% in quantity, and ran 23.2 Pb. The tailing or waste from the canvas plant was 79.8% of the total in weight, and ran 2.9 Pb, containing 48.4% of the total lead, 86.2% of which passed 200-mesh, representing 41.7% of total lead. The minus 200-mesh of this was 60.5% in weight, and ran 4.1 Pb. It can be clearly seen that 90.7% of the total lead in the pulp fed to the canvas would pass 200-mesh, 45.9% of which was lost as tailing from the canvas plant. The product for re-treatment was subsequently run over a slime table, with a saving of 84%. It is fair to suppose that had the entire tailing been properly sized and prepared, at least 80% of the total lead could have been delivered to slime machines, and that on the same basis 67.2% of the total could have been recovered instead of 43.3, as was the case.

In direct comparison the case of another mill using a large spitzkasten for preparing the slime pulp may be cited. This mill was treating a somewhat similar ore, but crushing to 60-mesh. All tailing, amounting to 80 tons, was run into a spitzkasten 30 by 10 by 8 ft., having five compartments. The first four drawings were made for experiment, and to determine the value in the products. The average value of these four combined was 0.5% lead and the weight was 55 tons. The fifth draw off, of 25 tons, ran 5% lead, and would all pass 200-mesh. The overflow water was perfectly clear, and while it must be admitted that some valuable slime was held in suspension, the amount was conspicuously small when compared with losses from canvas tables. Thus it will be seen that 82% of the value was retained in a product ready for treatment on the slime concentrators, while the product from the canvas plant contained but 51.6% of the value, and was not in proper condition for economical treatment, as it was necessary to rehandle it. After dewatering in the spitzkasten, a subsequent saving was made on the slime tables of about 80% of the lead in the pulp fed to them, or about 66% of the total lead.

Another point worthy of consideration is the possibility of re-using the clear water from the overflow of the spitzkasten for the purpose of washing in subsequent treatment, thus economizing in the use of water, which in many cases is important. Many other cases could be cited. They would be parallel in results and conclusions, so these are used as typical. In the use of the spitzkasten there is a series of operations carried on contemporaneously, all of which tend to the advancement of the work in hand. These operations are: sizing or classification, dewatering, and partial concentration. A sketch of one similar to that used at the mill referred to is shown. See Fig. 2. The sizing in this case was nearly perfect, ranging from 60-mesh to 200-mesh in regularly decreasing sizes, merging, of course, from one into the other. The ultimate object was, however, attained—the separation of the 200-mesh material which, of

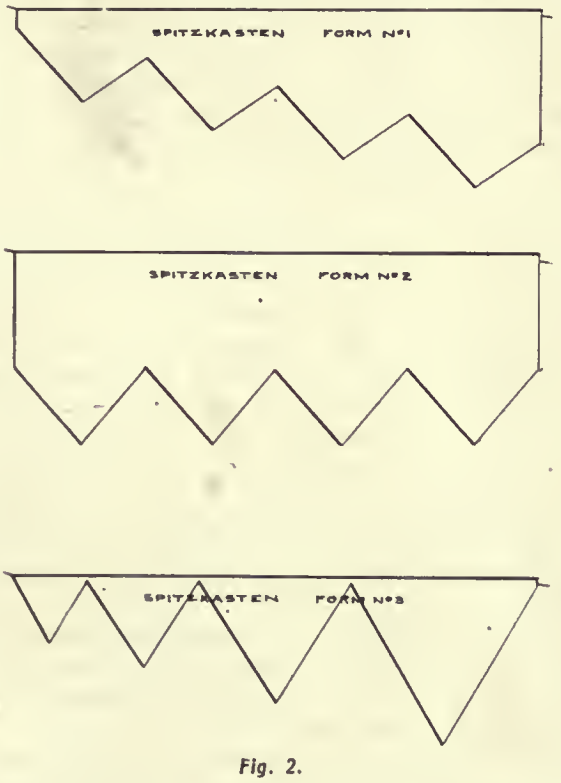


Fig. 2.

itself, carried such a large proportion of the escaping mineral. The consistence of the products from each draw-off was easily regulated by use of plugs and goose-necks, so that pulp was dewatered to any desired proportion of solids. The discharge was automatic, continuous, and regular, affording the best of conditions for proper subsequent treatment. It is obvious that by recovering the 200-mesh material in one product, since the bulk of the value is in this, a partial concentration was accomplished.

It has been stated that any current causes losses of slime. While this may be strictly true, there is a certain settling action in the slow movement of water in a body, which can be employed to advantage. This statement is based on observations made in several cases. For instance, a portion of the pulp at one mill was placed in a closed bottle and shaken thoroughly. At the end of 12 hours the pulp had but imperfectly settled, the water still being cloudy. The pulp stream from which this sample was taken was regularly delivered into the spitzkasten. The volume

of this stream was sufficient to fill the entire spitzkasten in about one hour, thus giving a current of 2 ft. per min. in a body having 35 sq. ft. of area. The water from the overflow was clearer than the supernatant water in the bottle, and still had but one hour for settling. A simple cause to which this may be attributed seems to be that in its slow motion the relation of water particles is continually changing, the more readily allowing the mineral particles to assert their superior gravity, while in a quiescent state the mineral particles become, in a way, lodged. Electric action has been suggested as a possible cause.

There are several forms of the spitzkasten, the various differences in form being due to difference in personal opinion. They all, however, have a general resemblance. Sketches of three forms are given. Fig. 2. These cover the ground in the order of their comparative theoretical effectiveness.

The first, form 1, is constructed with an increasing width and depth, allowing a gradually decreasing speed of current. As a result the settling tendency increases, and, as the cross-section of the flow is small at the beginning, the finer portions will be carried ahead the more readily to the compartment beyond, where it is designed they should settle. This form can be so designed that the cross-section progressively varies in such manner as to rapidly increase as the current passes beyond each of the divisions, giving a correspondingly decreasing speed, and as the pulp passes the apex or point of the hopper from which the draw-off is made, it has attained its minimum speed. From this point there is a practically uniform area of cross-section, to a point near the next division. It then decreases in area, slightly increasing the flow for a short distance, but the moment it passes this ridge the area increases rapidly as before to the point of the hopper, repeating this at every successive section with a decreased speed in each instance. The advantage of this action is obvious, and is clearly demonstrated in the figure showing this form of spitzkasten. (Fig. 2.)

The form 2 shown, is efficient and it was on a spitzkasten of this form that I made most of my observations as to action and effect. In this form it will be seen that the progressive sectional areas are increased and decreased in a series of identical fluctuations at each one of the sections, but there are two things which seem to assist in the classification and final settlement. One of these is that a portion of the content is drawn off at each successive spigot, and by just so much is the speed of the flow retarded. Another is that, in the matter of the finest of the material, the settling action is so slow as to hardly reach deep enough to be affected by the separating ridges until the pulp has traveled a considerable distance from the initial or feed end. Above the dividing ridges, is what might be called the effective sectional area of the moving body of water. Its sectional area in this case was 34⅓ ft. or about 86% of the total area figured to the apex. The spaces between the partitions can be said to contain practically dead water and consequently cannot be figured as effective, merely acting as a body in which the particles that are carried to it are at rest.

In the operation of this spitzkasten it was found that, when running normally, the water of the overflow end was, what might be called perfectly clear for a depth of about 14 in. from the surface. As the overflow was shallow and broad, the effect was that of drawing off from the surface without agitation. In this way the slime pulp was kept quiescent. In case any material is floating, and it is necessary to prevent this from going out with the overflow, a very shallow baffle-board could be placed across the spitzkasten near the lower end, but it should not extend down into the body of water enough to cause any disturbance to the pulp.

The third, form 3, resembles the first in appearance only. It is composed of a series of independent inverted pyramids, the divisions between them being extended nearly to the top of the spitzkasten.

It would need no special argument or discussion to show the faulty action in this form, and reference need only be made to the fact that what work may have been started in the first compartments in the way of settlement of the finer material is entirely defeated as the pulp is brought back to the surface and passes over each successive dividing partition. In this way the work has to be started all over again as each partition is passed, and effective settling is only done in last compartment. To the classifying action there would probably be less objection, but it can hardly be proved superior in this regard to the first form.

A new form of spitzkasten has been recently invented and patented by C. L. Buckingham, of Denver, which has some interesting features. The principal departure from the regular form is on the application of burlap screens in such a manner as completely to arrest the movement of the slime and to strain the overflow water. The entire top is covered with strainers and, as the head of the feed water is slightly higher than the plane of these, the water is gently forced up through. In addition to these strainers, others are placed underneath them in a sloping position, the action being to clarify the water to a great extent before it reaches the upper ones. It is a well-established fact that if any woolly, or coarse-woven fabric, such as burlap, is placed across the flow of water carrying slime, the minutest particles will attach themselves to the little filaments, and in time form a spongy porous mass which acts perfectly as a filter. This action would evidently take place on these screens, and experiment seems to prove that it does in this case. The arrest of the slime material is said to be complete, and on gaining sufficient weight it drops off, is carried ahead, and drawn off at the proper point. Draw-off cocks are placed at intervals and the pulp is taken from them at any desired solid consistence, as in the regular form. Another claim, which seems to be well founded, is the possibility of making a thorough classification.

When only settling and dewatering without classification is desired, simple conical or pyramidal tanks are often used. It is customary in such cases to feed at the centre of the tank, using the entire periphery for discharge of clear water, drawing off the thickened pulp at the apex. The Callow tank may

be cited as an excellent example of this class. This tank is conical, having a height of 7 ft. 7 in., and an effective width at the top of 8 ft. I have found it possible to settle about 20 gal. per min. with this. The amount of solid material possible to handle in tank of this kind depends, consequently, on the consistence of the material fed into it. For instance, if the feed to the tank should be 10% solids, from 20 to 25 tons per 24 hours could be readily handled and properly prepared. In cases where, from the use of hydraulic classifiers for instance, the consistence of the pulp should be as low as 4% solids, which has been met with in actual experience, the efficient capacity is materially reduced. In the use of the conical settling tanks the point giving the greatest amount of trouble is the tendency or liability to choke at the apex. This is due to the fact that everything of a solid character has to pass out through the opening at the point where everything is bound to settle. Avoidance of this trouble has been attempted in several ways, principally by the use of a system of pipes carrying a high water-pressure, by which the clogging material is forced back into the tank. This is at best only temporary, and when the pressure is removed the same condition is liable to recur.

A form of draw-off might be suggested for consideration that has been applied in some cases, though no statement of actual results is available. In this form there is an auxiliary chamber attached to the side of the tank that is in the form of a long tube having an opening into the tank for almost its entire length. The lower end is closed. At the upper is placed a gland through which is inserted a pipe, the lower end of which reaches nearly to the lower end of the auxiliary chamber. This pipe is used as the draw-off acting in the place of the ordinary goose-neck. In this manner the initial point of draw-off is removed a little distance from the apex. In case there is a clogging of the draw-off pipe, it is only necessary to withdraw the pipe sufficiently to reach a point where the thinness of the pulp will insure a free flow, thus immediately re-starting the action of the tank. The pipe is then gradually returned to its original position, thereby cutting out the thick pulp that may have collected. Any foreign obstacle is more than likely to settle into the apex itself at some distance from the point of draw-off. The hose connected to the upper end of the pipe can rest on a roller or convenient support, so that in withdrawing the pipe the established height of the goose-neck will remain constant. A pressure pipe may be applied if considered necessary.

The Geological Survey has made field and laboratory studies of many kinds of sands and gravels in localities where Federal buildings are in course of construction. These studies have shown great differences in the quality of sand and gravel used at different places for making concrete. Some contractors contend that run-of-bank sand and gravel is the best for making cement concrete, but this contention is generally not sustained by practical trials and experiments. The most desirable material is that which is free from clay, loam, or dust.

EXPLOSIVES FOR TUNNEL DRIVING

Selection of explosives for tunnel blasting probably requires a more careful study of conditions than for any other kind of excavating. Maximum speed in driving cannot be attained unless the explosive best adapted to the work be used. When starting a tunnel or drift, it is a good plan thoroughly to try several explosives which differ in action before finally adopting any one. The results, however, from this preliminary trial will be of little or no value unless each explosive is used under exactly the same conditions. Care must be taken to allow for change in the character of the rock, number and direction of the bore-holes, strength of the detonator, kind and quantity of tamping, amount of water, and method of connecting the bore-holes for firing. If possible, these conditions should be uniform throughout the test. If a material change in any of them does occur as the work progresses, further tests should be made to determine whether a quicker or slower, a stronger or weaker, explosive might not break the ground or bottom the bore-holes better, or make it possible to bring out the cut with fewer holes or deeper ones. The speed at which rock can be drilled does not indicate how it will break, and not infrequently that which can be easily drilled is very difficult to blast.

High explosives suitable for tunnel blasting should not give off objectionable fumes on detonation, and accordingly gelatin dynamite, blasting gelatin, or ammonia dynamite are recommended. Gelatin dynamite is made in various grades of strength, from 25 to 80% inclusive. It is comparatively slow in action, the higher grades being little, if any, quicker than the lower ones. Blasting gelatin is manufactured in only one strength, which for comparative purposes may be said to be 100%. It is more powerful and quicker acting than any other blasting explosive. It should be used sparingly, therefore, until the maximum safe charge has been learned from experience. Good results will often be had in hard ground if a few cartridges of blasting gelatin are used in the point of the bore-hole, with gelatin dynamite on top. When this is done it is best to put the detonator in one of the cartridges of blasting gelatin. Ammonia dynamite is made from 25 to 75% strength. All grades are quicker than gelatin dynamites, and generally speaking the quickness increases with the strength. That is, the stronger grades are quicker and the lower grades slower in action. The various grades of these three high explosives offer a wide range in strength and quickness from which to select.

Railroad tunnels, mine tunnels, and drifts, highway tunnels, and irrigation tunnels are being driven daily through various kinds of 'ground.' Often it is a matter of first importance to finish them quickly, and consequently details in regard to methods and equipment are matters of general interest. No matter what explosive is used in blasting, maximum results can only be attained by always having the explosive in a thoroughly thawed condition when it is used, by tamping firmly with earth, from the charge of explosives to the mouth of the bore-hole, and by using the strongest detonator that can be secured.

Iron Ores Near Dayton, Nevada

By E. C. Harder

*Dayton is a small village in eastern Lyon county, Nevada, on the Carson & Colorado branch of the Southern Pacific railroad. The village is on Carson river at the upper (southwest) end of a broad flat desert, just below the point where the river runs out of the canyon below and east of Carson. Two groups of iron-ore deposits are found near Dayton—a small one about two miles to the southwest, between the railroad and the river, and a large one about twelve miles to the northeast, on the boundary of Lyon and Storey counties. Only the latter is of commercial importance in the steel industry, but the ore from the former might be used in a small way as fluxing material.

The deposits northeast of Dayton are in an area of gently rolling hills which form the northeastern continuation of the flat desert area below Dayton. Northeast of the deposits there is another desert area with alkali flats, and beyond are other rolling hills. This generally low belt bounded on the northwest and southeast by mountain ranges is known as the Fortymile desert. In the mountains to the northeast is the famous old Comstock Lode, with Virginia City and Gold Hill high up on the slope. The iron-ore deposits are near the northwest border of the desert belt. Outcrops of ore are distributed over an area roughly one-fourth of a mile wide and half a mile long, the longer diameter being approximately north and south. At the south end of the area there is a hill rising about 75 or 100 ft. above the surrounding area. Its crest is about 900 ft. long and 200 wide and trends about N. 45° W. Iron-ore outcrops form the crest and extend some distance down the slope. From the distribution of ore and rock as shown by outcrops and pits it appears probable that the area is underlain largely by soda granite, in part aplite, in which there are local masses of limestone and iron ore. Where the relation of the ore to the rocks is clear it is seen that the ore occurs at the contact of the limestone and granite. The soda granite has also broken into the limestone and ore masses in irregular intrusions. Metamorphic minerals, including garnet and epidote with a little albite, are developed locally.

The outcrops of ore on the hill at the south end of the iron-ore area occupy a space about 1000 ft. long and from 200 to 500 wide. Within this area there are one or two tongues of granite and the float between the outcrops may cover limestone or other granite bodies. The surface ore on the crest is hard and massive, though slightly porous in places. One shaft and several pits have been sunk into it. The pits have not passed through the hard ore, but the shaft goes into a soft, bluish, granular mixture of magnetite and calcite at a depth of less than 20 ft.

On the northwest slope of the hill some porous, hard, low-grade ore, with considerable impurities consisting largely of unreplaced silicious rock, outcrops on the lower slope, but most of the ore outcropping on the upper slope is hard and massive, though mixed irregularly with it is the blue granular ore already mentioned.

From their occurrence the ores northeast of Dayton appear to be contact deposits formed during or after the intrusion of the granite into the limestone. This view is strengthened by the presence of minerals characteristic of intrusive contacts. The ores are probably partial replacements of the limestone, some of the original limestone being still present as local masses in the vicinity of the ore or

occuring in the recrystallized form of calcite within the ore. The surface ore has been enriched and concentrated by the removal of calcite and probably by the deposition of iron oxides. The selenite may be simply a deposit near the surface from gypsiferous solutions or the sulphur in it may have been derived from the oxidation of pyrite.

Most of the surface ore is of high grade. In depth it appears, whenever penetrated, to be strongly impregnated with calcite. Locally enough calcite is present to make the ore self-fluxing, and therefore in reality the presence of calcite does not materially affect the value of the ore. The selenite may be abundant enough in places to necessitate dressing of the ore to reduce the sulphur content. If the ores were smelted in the electric furnace, however, the presence of selenite would not be objectionable. The depth to which the ores may extend is problematic, though the increasing amount of calcite with increasing depth suggests that the ore may become of too low grade to be worked. But the deposits are of sufficient size to be commercially important even if the ore is supposed to be relatively shallow. With a depth of 50 ft. the deposit on the hill at the south end of the area would probably yield approximately 1,500,000 tons of ore. The deposits are on low ground and can easily be approached by a railroad. Veins of iron ore also occur in a dark-green fine-grained andesite on the east slope of a ridge about two miles southwest of Dayton.

*Abstract from Bull. 430-E, U. S. Geol. Survey.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

A Cyanide Problem

The Editor:

Sir—There are many contributions to the technical press dealing with the cyaniding of gold and silver ores, and numerous books on the subject, all of which give valuable data, metallurgical, mechanical, and economic, but there are still phases of the treatment of certain refractory ores which none of these authors mention, or, if they do, in only a casual manner, throwing little light upon vexed questions. I have in mind an ore consisting of a quartz gangue in which occurs pyrite in abundance, with a relatively small amount of galena, blende, and chalcopyrite. The value is chiefly in gold, which to some extent is free, that is, it may be panned, but accompanying it is silver, which mostly occurs as a complex antimonial compound. This ore has thus far successfully resisted all efforts to treat it either by amalgamation or cyanidation, the tailing still carrying nearly half of the original value of the ore. If some one of the numerous contributors to the extensive literature of the cyanide process would tell how the antimony in this ore may be eliminated, or at least rendered innocuous, it would be appreciated by many having mines producing ores of similar character. It is quite possible that roasting before cyanidation, or roasting in connection with the chlorination process, would solve the problem, but the additional cost of handling and roasting in a region where fuel of any kind is far from abundant makes the treatment of the raw ore desirable, if not necessary, for reasons of economy. Then, too, it is not always an easy matter to secure the services of an expert roaster, such as would be imperative in the handling of an antimonial ore. Arsenic is bad enough, but antimony is worse.

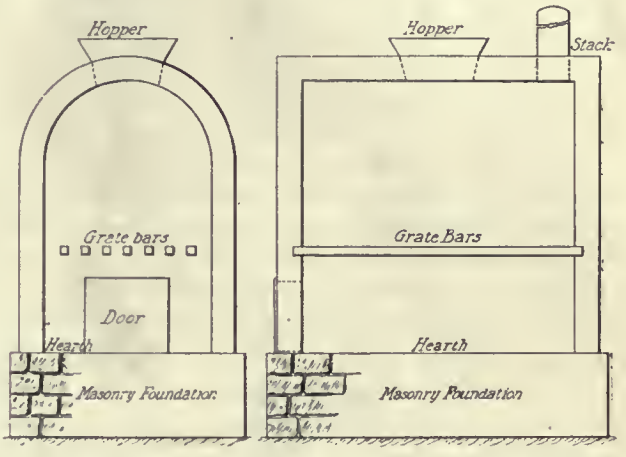
MINE OWNER.

Tucson, Arizona, August 5.

Furnace for Burning Mill Chips

The Editor:

Sir—Wedges from the boss-head, chips, and other small bits of wood from the mine are always finding their way into the mill mortar. Where amalgamation is practised inside the mortar, amalgam attaches to these bits of wood. These bits of wood should be saved and burned and the ashes worked in the clean-up barrel with quicksilver. A suitable furnace for this purpose may be built of brick after the design here illustrated. Convenient dimensions are: From hearth to top of the grate bars (made of pieces of old T rail), 15 in.; from top of bars to centre of arch, 48; inside length, 48; inside width, 30. The furnace should be built with an opening at the front extending from the hearth upward to a height of 10 in., and this opening should be provided with a door, for the purpose of regulating the draught. In the top of the arch should be left a hole, either square or round, in which it would be well to arrange a hopper for convenience in feeding the chips to the furnace. At the back end of the furnace, either in the end or the top, a hole must be left which should be fitted with a stack. The furnace may be constructed on a foundation of stone masonry, or may be built level with the ground, as suits the fancy of the builder. If elevated somewhat, a receptacle may be placed below the door to receive the contents of the hearth when it is drawn out. The hopper can



be of sheet iron or steel, or may be omitted altogether, if desired, though it would be found very convenient. There is usually suitable material lying about the mine from which to make one at little cost. At the bottom of the hopper, which should set about the middle of the arch, should be arranged a cover of some sort—a heavy piece of steel plate, such as that from which skips are made will do. It should be provided with a ring, so it can be readily lifted when necessary. The smoke stack may be of ordinary stove pipe, as the heat will not be greater than that from a stove. Chips can be completely burned in such a furnace as is here described, and all the gold contained in them recovered at small expense.

MILLMAN.

Angels, California, August 3.

Are Engineers Honest?

The Editor:

Sir—I send you an abstract from a letter received not long since from a friend who clearly sets forth his ideas as to why so many business men look upon mining investment as unsafe.

"The false note of which you speak regarding the visit of a mining engineer to the Oriental mines was not written by me, but by Mr. H——; an old practical miner who has a distinct dislike for the average mining engineer; and I don't know that he is far from wrong, as I can say that personally I have found about one out of twenty that can be trusted when it came to the fine point of honesty. I have seen business men (manufacturers) pass upon a mine who had almost no knowledge of mining, but who with the help of a practical mining man were able to make about as fine a talk on a mining property as I have ever listened to. A mining engineer sent out by possible investors themselves is all right, but a mining engineer in a local community of mines al-

most invariably favors his locality, and you know yourself, as a mining man, that it is a mighty easy thing for such a man to keep his skirts clean while giving wrong advice; in fact, advice that he knows he is not warranted in giving. I have seen this done many times where a mining engineer recommended a property he knew did not stand one chance in a thousand of making good. Nearly every mining company that launches a new mine has one or more reports by mining engineers, and there is about one in fifty that is worth more than the paper it is written on: these reports are paid for by the mining companies, and the engineer examines just what they direct him to examine and nothing more, and makes his report accordingly. It is time that reputable mining engineers, for their own good, wake up to the fact that their profession is being abused; and they should band themselves into a society for clean methods and the elimination from their ranks of the dishonest undesirable element. Mr. H—— has seen a lot of 'hungry coyotes' in the garb of mining engineers who have robbed Easterners by false reports and done a vast amount of damage to legitimate mining by the recommendation of properties which had hardly a speculative chance of making good. He said in his letter, 'go yourself,' and my experience teaches me that he is pretty nearly right, because, if a common-sense business man will go to a mine and examine it in the same way that he would examine anything else he is buying stock in, he would seldom make a mistake. The great trouble with visitors to a mine is that they generally make it a junketing tour, hustle around with a beer or whisky bottle in their hands, are captivated with the thought that they are finally miners, and go away knowing as much about the property as when they came."

COMMON SENSE.

Denver, August 3.

[While we object to the sweeping condemnation of engineers, there is much good sense in the above. It calls to mind an examination made by an engineer not long ago of a group of mines in Mexico. The property was situated 60 miles from the nearest railroad and was in charge of a man who was a respected fellow townsman of the Americans who were furnishing money for operating the property. After spending many thousands of dollars in development it was considered good business to have an engineer's report, notwithstanding that the owners had in their possession three typewritten reports by as many engineers, and a printed prospectus containing statements abstracted from these reports and also evidently obtained from other sources. The directors of the company employed an engineer and directed him to make a careful examination and exhaustive report, and he accordingly went prepared to remain a month, or longer if necessary.

The mines were reached without any unusual difficulty, the description of the situation of the property in the reports, proving accurate. This, and some figures giving approximate elevations of points in the vicinity, were the only things that approached truth in the entire lot of reports. Several veins and their workings had been described at length. One was said to be 12 ft. wide, developed by two adits, about 100 ft. vertically apart. The ore sent to the home office showed 'free gold' in alluring quantity. Another vein was said to outcrop from the river up the side of a mountain to its summit, 800 ft., and to be valuable, although it had not been developed. A third could 'be traced' by its bold outcrop for several thousand feet through the property, and was opened by various shafts, adits, and open excavations. It was described as being 10 to 20 ft. wide, and 'beautiful ore.' Still another vein was so rich that the *gambucinos* had systematically robbed it at every opportunity.

After arrival at the company's camp it did not take the visiting engineer long to learn the true conditions. The first vein, '12 ft. wide,' had dwindled to a miserable little streak less than 2 ft. wide at its greatest breadth, averaging 8 inches in the two adits (which, strange to say, were actually found to have been driven). At one place, in one of these adits, the vein where 4 in. wide showed a little gold. This 'shoot' was less than 4 ft. long. The average value of ore from these workings was less than $2 per ton. An examination of the great vein 'running uninterruptedly for 800 ft. up the side of a mountain,' proved it to be a sheet of quartzite 40 ft. thick lying on top of the hill, and of a remnant of the same sheet capping another hill-top near-by. Worse than this, there was no gold in the rock. The other large vein of 'beautiful ore' did outcrop at intervals, and about 300 ft. of work had been done on it, but the rock was extremely hard and was low in grade to match its adamantine character, while the miserable *gambucinos* had extracted every pound of ore. Two days of climbing over the hills and three days sampling were all that were necessary to prove the absolute worthlessness of the entire property. But what of the manager? He lived, 'Mexican fashion,' in an abode house at the camp, kept a store, stocked at the company's expense, and in addition to his salary made considerable profit selling goods and provisions to the natives who lived for miles up and down the river. He seldom if ever went up on the hill, had an easy time, and was 'doing well,' but no longer thereafter than it required for the company to close the mine and order him home. He closed the mine, but did not go home.—EDITOR.]

The Shasta region in California, recently described by L. C. Graton of the U. S. Geological Survey, is the second largest copper region in the United States that can be considered a geologic unit. In shape it forms a curved belt 35 miles long, popularly known as the 'copper crescent.' Copper sulphides have been known to occur with the gold lodes of this region for many years, but were not handled until 1895, and since that year the region has produced 300,000,000 lb. of copper. In 1909 it produced 50,000,000 lb., which makes it rank as the sixth or seventh copper district in the United States. The ores are pyritic and are of medium richness, averaging 3 to 3½%. Some of them form the largest sulphide orebodies in the world, measuring 1200 by 300 by 300 ft. They represent, not the filling of cavities, but the replacement of the surrounding rock.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

A flow of 200 miner's inches of water under a head of 300 ft. will develop theoretically 135, and actually 122 horse-power.

A grade of 5 in. in 100 ft. is that commonly given tracks in mines where the cars contain 1800 lb. and tramming is done by men.

Oil has never been discovered in any well in the Mojave or Colorado deserts of California, although several have been bored.

In surveying vertical shafts it is advisable to use heavy plumb-bobs—up to 200 pounds in very deep shafts, as their use insures greater accuracy.

Gauge-cocks on steam-boilers should always be kept in good order, and should be tested frequently, as the water-glasses are known to be unreliable.

High voltage when distributed from a generating plant to consumers on three wires is not divided between these wires, but each carries the same voltage.

Tin occurs in a number of the States from the Atlantic to the Pacific, but contrary to popular belief the Government has never offered a reward for its discovery.

Measurements can be made in a rugged or brushy country by the careful use of a transit fitted with stadia wires with fully as much accuracy as with tape or chain.

To ascertain the force of a current of air in a mine, multiply the square of the velocity of the air in feet per second by 0.0023. The velocity of the air can be measured by an instrument called an anemometer.

Metal tamping bars are illegal in several of the Western mining States. The fact does not seem to deter careless miners from using an iron spoon, or other iron rod, if it chances to be handy. The practice is extremely dangerous and men are not infrequently injured in this manner.

Drift mines in California are extensive. The largest is the Hidden Treasure-Mountain Gate, at Sunny South, Placer county. The workings here extend more than five miles under cover, and the greater part of the channels are buried beneath 1200 ft. of volcanic débris.

In blasting, miners should remember that with high explosives, the stronger or sharper the initial shock given by the exploder the more complete is explosion of the charge of powder, and the less the quantity of gas formed. The low-grade caps (detonators) XXX often used, are considered less dangerous. This is true in so far as the quantity of mercurial fulminate (which is the exploding substance), is concerned, for its explosive force is in proportion to its volume, but a small quantity of fulminate is liable to lack sufficient force to explode the powder as quickly and completely as the higher-grade caps, those containing a greater amount of fulminate, such as XXXXX, XXXXXX, and what are known as No. 30 special caps. These, though a little more expensive than the detonators of lower grade, are far more economical.

The silver content of a solution of KCy may be determined by adding to a measured quantity of the solution to be tested a standardized sodium sulphide until a drop removed by a glass rod will give a brown color when added to a drop of alkaline lead tartrate solution. If sodium nitroprusside be added the color will be purple. Place the two drops side by side on a piece of white filter paper, and when the liquids unite the color will at once become apparent. The sodium sulphide solution can be standardized by adding in excess a solution of double cyanide of silver and potassium, filtering and titrating the liberated cyanide in the usual manner, after adding potassium iodide. The following equation represents the reaction:

$$1 \text{ gm. KCy} \begin{cases} = 0.3 \text{ gm. } Na_2S \\ = 0.8284 \text{ gm. Ag} \end{cases}$$

Vanadium ore is treated at Newmire, Colorado, and its reduction to a commercial product is accomplished in the following manner: The ore is crushed to 1-in. size in a breaker, then passes crushing rolls where it is ground to 20-mesh. It is then introduced into a reverberatory furnace with the addition of salt. It is rabbled and worked toward the discharge end of the furnace by hand and is drawn out on a cooling-floor. As a result of the roasting sodium vanadate is formed with the liberation of chlorine. The ore, when cool, is placed in a tank and water turned on, which dissolves the sodium vanadate, compressed air aiding in the process. The solution is drawn off and the vanadium precipitated as ferro-vanadium by the addition of a solution of ferrous sulphate. In this form it is sold to the trade. The price is about $5 per pound for the metallic vanadium contained in it. There are several other processes for treating vanadium-bearing ores, but that above given is the simplest.

No legal responsibility attaches to the owner of a mine for the misrepresentations of promoters, to whom he has given an option to purchase the property, unless said owner is a party to such representations, and the agreement between owner and promoters states that the money to be paid for the property is to be raised wholly, or in part, by the sale of stock in a company organized for the purpose of raising money through the representations of the promoters. The owner is presumed to know nothing of such misrepresentations, and is therefore not in duty bound to make known to prospective purchasers of stock that they are being deceived by the statements made by promoters. The question has an ethical as well as a legal side, but even if the mine-owner has knowledge that misrepresentations are being made concerning the property, he is not legally compelled to make such knowledge public.

Special Correspondence

LONDON

Cornwall Mines. — Hingston & Clitters. — Wheal Kitty & Penhalls.—De Lamar Improves Mill.

The Hingston & Clitters Co., operating in East Cornwall, is again looking for capital. The present company was formed in 1908 as a reconstruction of Clitters United. The mines are old tin properties containing wolfram and arsenical and cupriferous pyrite, and they were reopened in 1900 by the Allen-Schiff group. A modern dressing plant, which has the distinction of having been the first to separate the tin and wolfram magnetically, was provided. The unfortunate part of the business was that the plant was erected at the Clitters instead of the Hingston mine, for the best ore is found at the latter, and it has to be transported more than a mile to the mill. Also the underground development was neglected and the mill erected before any reserve was proved. The old shafts which were crooked and in bad condition were used instead of a new one being sunk. Modern ideas were applied to the metallurgy and not to the mining. In the course of a few years the control passed to the Schiffs, Mr. Allen retiring. In 1908 the crisis came, for unearned dividends were paid, and the results of operations for 1907 ended in a serious loss. In addition the Hingston mine was flooded and there was no money available for additional pumps. The control then changed hands, and Mr. Allen once more came forward to provide funds on the reconstruction in 1908. Electric pumps were bought and the Hingston mine unwatered; the Clitters had never been worked below an adit. By the time the mine was put in order the funds were exhausted. R. T. Moore, of Glasgow, has examined the mine, and reports that about 15,000 tons of ore is in the mine; he recommends further developments at points specified at an expenditure of £10,000. If the results are satisfactory he advises the removal of the mill to Hingston at a cost of £5000 and the provision of a further £10,000 as working capital. He reports the plant to be in excellent condition; it consists of 25 California stamps of 1050 lb. each, 9 Buss tables, 10 Frue vanners, roaster, magnetic separator, and an Elmore vacuum plant for removing pyrite. At the present time it seems impossible to raise any more funds; one drawback is the existence of £18,800 of debentures the interest on which is accumulating dangerously. The company makes a small profit by treating tin-wolfram-pyrite concentrate bought in the market from all parts of the world, but as this class of business requires ready cash, the operations in this direction are naturally cramped. Wheal Kitty & Penhalls in the St. Agnes district of Cornwall is doing well and continues to make substantial profits. The report for the half-year, January to June, shows that the extraction per ton was less than during the previous four half-years, but as the stamps treated a greater quantity of ore and the price of tin was higher, the total receipts show an increase. The ore treated was 7191 tons, and the concentrate recovered 121 tons, being a yield of 37.7 lb. per ton. The average price received was £94 and the receipts £11,402. The new main shaft, Sara's, is now down 560 ft. and drifts are being cut east and west on a lode met at 540 ft. It is the intention to continue sinking another 300 ft. in order to reach the Kitty lode at depth, and in order to supply the necessary funds, 14,000 preference shares of 10s. each and bearing 10% dividend are being offered to shareholders and others. The money thus received (£7000) will also be sufficient to provide additional dressing and pumping plant. The shaft has four compartments and measures 15 by 7 ft. inside timbers; it is a good example of modern practice. The working cost during the half-year shows a decrease, and, considering the small scale, the number of different workings, and the large proportionate amount of development work, shows a careful attention to business. The total cost was 23s. 5d. per ton, of which 7s. 11d. was for mining, 4s. 10d. for development, 2s. 6d. for pumping, 5s. for dressing, and 3s. 1d. for repairs and administration. In addition royalties of 1s. 7d. brought the expenditure to 25s. per ton. During 1909 the corresponding figure was 25s. 6d., and during 1908, 26s. 11d. It must be remembered that old-fashioned Cornish stamps and dressing plant are still employed, as the company has never had any extensive supply of capital. In profit and loss for the half year the total receipts were £11,643, the costs £8984, leaving a balance of profit of £2659. From this, £609 has been allowed for depreciation of plant, etc., and £778 has been written off for the cost of Sara's shaft. The balance, with £1906 brought forward from 1909, gives a disposable balance of £3177. In order to provide funds for working capital a dividend of only 2½% for the six months is being paid, absorbing £664, so that £2513 is held in hand.

The De Lamar company, operating a gold and silver mine in Owyhee county, Idaho, was floated in London in 1891. For five years the profits were high, but on the exhaustion of the chief veins the dividends sank to next to nothing. Recognizing that the mine might still continue to be a producer on a smaller scale, the capital was reduced in 1901 from £400,000 to £80,000. During the nine years since, the total distribution has been 92% in the smaller capital. The mine continues to yield profitable ore which is obtained chiefly from old stope fillings and wells and by prospecting for stringers and bunches. In this way 44,961 dry tons of 2000 lb. was sent to the mill during the year ended March 31, estimated to contain $8.41 in gold and $3.23 in silver. The extraction was 17,121 oz. gold and 180,114 oz. silver, leaving 95c. gold and $1.51 silver in the tailing. The revenue was £91,604 from sale of bullion, and the costs at the mine and in London were £88,967. The company also received £398 from the sale of obsolete stores and £1172 from interest on loans. The available balance of profit was £4142 and £4000 has been distributed as dividend. The company has a reserve fund of £27,000 invested in loans at short call. The manager, Ernest V. Orford, reports that during the year £2000 has been spent on additional concentrating plant, consisting of eight Deister slime tables and two Wilfleys, the object being to make a better separation of the refractory constituents of the ore found below the eighth level. By means of this plant the extraction of the silver will be greatly improved.

FAIRBANKS, ALASKA

Iditarod. — Quartz Mining near Fairbanks. — Milling.—Placers.

Although for several weeks after the stampede to the Iditarod, Fairbanks was a lonesome town and all operators were short of men, the first two boats from the outside brought limit loads of passengers and the mines are now full-handed. If the report is true that there are still 1500 men headed for Fairbanks to work in the mines, much suffering will result later. The opportunities are many for the prospector, both for quartz and placer, but after a certain limit, there are no openings for laborers. Reports from the Iditarod average about the same in that the class of people there who live off the population think the camp is good while those trying to work ground assert the camp is much overpopulated. Several clean-ups have been made, some exceeding expectations and others falling far below. The *White Seal* brought several thousand dollars in dust to Fairbanks on the last trip, mostly in small lots. A characteristic of the dust is the prevalence of cinnabar, especially noticeable in Otter Creek dust. This is hard to clean from the gold before melting and some melts have lost as high as 6 per cent.

Many of the 'cheechacoes' have started prospecting for quartz and in one case have met with gratifying results. Four partners have opened a 16-ft. vein on Vault creek that promises exceedingly well. Between the well-defined walls are 16 ft. of vein matter consisting of graphitic schist and quartz in which free gold can be readily seen. Three claims east of this find, Louis Fredericks, an old-timer, has found a 4-ft. vein which is the typical gold-bearing quartz of the district. A vein of antimony lies on one wall. Assays made recently show from $40 to $133 per ton. Below the adit at the head of Moose creek, E. W. Herschberger has picked up a small vein of rich quartz. It is a foot wide with high-grade filling. It should be borne in mind that

this district is several miles from the Cleary district, where so much good quartz has already been found. This explodes the oft-repeated 'knock' that all the Tanana quartz consists of a few stringers in the Cleary hill. Several miles down Fairbanks creek, the Cook brothers, while following a trace of gold, uncovered a 5-ft. vein that averages well the full width. On one wall is almost a foot of oxidized galena assaying 220 oz. of silver per ton. It is thought that sinking will develop a good orebody. Effort is being made to interest capital in the development.

The citizens' mill at Fairbanks has been enlarged to stamps of 500 lb., and a concentrator of the Frue vanner type has been ordered by telegraph. As the 10-stamp mill at Chena will not be ready to operate earlier than September 1, the Fairbanks mill will be running constantly up to that time. Lucien Rhodes will ship every other day from his Bedrock creek property till the big dump extracted this winter is all crushed. The Crawford lease on the same property will also ship as soon as the mill is idle. Awaiting treatment at the Fairbanks mill is about a ton and a half of high-grade ore from the Sommersett & McCarty vein at the head of Fairbanks creek. As this is mostly 'picture rock', it is expected to break the present high record for Tanana quartz.

Work is still being actively pushed on the Redwing lease of the Jupiter Mars. The vein has been struck at a depth of 60 ft. and a hoist is to be installed shortly. Mr. Furstenau has ordered a thousand sacks for shipping to the Chena mill this summer. Spaulding & Clough are still running their adit to tap the shaft at some depth. The vein continues strong with no diminution in value. Although some surface prospecting has hindered work during the month, the adit is in 60 ft. At the head of Skoogy gulch, S. Scafford and Charles Thompson have built a water-power arrastre with which they reduce about two tons of rock per day. Although no clean-ups have been reported, nobody is worrying as to results. Near this property, Faulkner & Bradley are driving an adit to tap a shoot of ore they know to exist from their previous operations. Their former adit was destroyed by a slide. Hess & Burnett have located a 2-ft. vein on the Cleary side of the summit that averages close to $50 per ton. Part of the rock is high grade and the owners expect to ship ore this season. What is supposed to be the mother-lode vein of the Fairbanks mineral belt is the 14-ft. vein of solid quartz opened in Dan McCarty's adit on Fairbanks creek. Croppings supposed to belong to the same vein can be traced for miles. It is understood that this vein is of sufficient value to warrant development. Mr. Buell, of Herschberger & Buell, brought in an average sample of their vein on Willow creek this week that assayed $160 per ton.

The output from placers in this district continues steadily. Four and five below Cleary are still in the old original Cleary pay, and the weekly clean-ups average well into five figures. In the Hot Spring district, Alexander, Morrison & Johnson, who acquired the Chute-Stier option, have had several satisfactory clean-ups. This is open-cut ground and will show even better as soon as the scraper is installed. Many of the open-cuts on Pedro creek in this district were filled by sand by the big rain and flood that again took out the Fairbanks bridge. Much delay and damage was caused.

Hot Springs District, in the Heart of Alaska. Glen Creek to Pioneer Creek.

TORONTO, CANADA

American Peat Society Convention. — New Districts.—Cobalt.— Other Camps.

The annual convention of the American Peat Society was held at Ottawa, on July 25 and 26, and was attended by 50 delegates, including several from Europe and Brazil. Eugene Haanel, Canadian Director of Mines, and president of the Society, occupied the chair. The importance of the development of the Canadian peat industry was dwelt upon, both by the president and Clifford Sifton, chairman of the Conservation Commission, special reference being made to the Canadian fuel situation. The coal deposits are for the most part in the extreme east and west of Canada, leaving the central portion dependent upon the United States for its coal supply. The forests, as a source of wood fuel, are being rapidly exhausted, while immense peat resources are undeveloped. Mr. Haanel pointed out that at present no estimate could be found of the enormous extent of the Canadian peat bogs. An area of 37,000 square miles was known to exist, but this was probably a mere fraction of their actual extent. In addition to the reading of a number of technical papers, the delegates visited the government peat plant at Alfred, witnessing the system in operation, full explanations of its working being given by A. Anrep, Jr., of the Canadian Department of Mines, a son of the inventor of the Anrep peat manufacturing machine.

The cost of producing a ton delivered on board the cars was given as $1.60. The methods employed were criticized as uneconomic by L. B. Lincoln, of the Peat Engineering Co., who claimed that by the substitution of machinery for hand labor better results could be obtained. The Fuel Testing plant of the Government, at Ottawa, was also inspected. A Canadian Peat Society was organized in affiliation to operate on the same lines, and a vigorous campaign will be undertaken to interest the public in the industry. Mr. Haanel was re-elected president. Among those in attendance were J. A. Gray, C. A. Meissner, and W. A. Forbes of New York, who were present in the interest of the United States Steel Corporation, which is keeping close watch on the development of the industry.

The Porcupine gold area is continually widening as new discoveries are made. Some important finds are reported from the new township of Deloro, south of Tisdale, one locality where several of the discoveries are situated being Gold Lake, some three miles south of Tisdala. The latest excitement among prospectors is over what is known as the Cripple Creek district, lying west of the Metagami and Lost rivers, and extending in a westerly direction as far as a chain of lakes in Denton township, all in unsurveyed territory. Such discoveries were made as early as May, but recent finds of a much richer character have induced something of a rush and much staking has been done during the last few weeks. The formation is similar to Porcupine, schist, porphyry, and quartz running into granite formation on contact. Most of the richer assays are from contact veins.

The small mill just built on the Timmins property was started for the first time on July 20, with highly satisfactory results, the ore treated running over $300 per ton. A new 30-stamp mill has been ordered by the syndicate. The shaft is 100 ft. down, at which depth the vein has a width of 10 ft. A company may shortly be floated. The question of power for the camp is engrossing much attention, as with the disappearance of the wood supply, it will be both difficult and costly to obtain fuel for the present and projected plants. As a means of supplying power a Montreal syndicate has acquired water-power rights at a point about forty miles from the centre of the district, and engineers are now making surveys and estimates of the cost of an electric plant.

At Cobalt the Nipissing, on July 18, cut a rich 8-in. vein at 275-ft. depth in shaft No. 64. It has since widened with driving and yields 1800 oz. per ton. The Buffalo is working on the 300-ft. level, which is the deepest mining in conglomerate formation in the camp. Vein No. 10, which was picked up at that depth, shows 4 in. of high grade yielding over 2500 oz. silver per ton. The Dominion Reduction Co. will erect a 100-ton custom concentrator at the Crown Reserve property on Kerr Lake. The shaft on the Union Pacific lease on Peterson lake is down 180 ft. It will be sunk to 200 ft. to allow of undergrounnd work below the lake. The Crown Reserve made an important discovery on July 21, being a 6-in. vein, assaying 3000 oz. silver per ton, 900 ft. distant from the nearest point at which pay-ore has so far been worked. The Cobalt townsite has reappeared in the list of shipping mines, sending away 24 tons of high grade. They have for some time been taking good ore out of the extension of some of the Right of Way veins. Charles Watson has been placed in charge.

A good surface discovery has been made on the Marathon property, South Lorrain, situated about a mile and a quarter north of the main mining area of the camp. The vein is of smaltite and niccolite, from 4 to 8 in. wide, and has been stripped for 100 ft. Silvers, Ltd., an unlucky Gowganda proposition, has been closed, a meeting of shareholders having decided that there was no prospect of its ever paying. The Dr. Redding Co., of Larder Lake, has gone into liquidation.

The charge of high-grading on a large scale that was preferred against George E. G. Rogers, captain of the Lucky Godfrey, at Elk Lake, and William Acker, employed as ore-sorter, came to nothing, the accused being discharged for want of evidence.

SALT LAKE, UTAH

Utah Copper Report.—Garfield Smelter Improvements.— Yampa Ships to Garfield. — Park City Changes. — Tintic News. — Wasatch Utah Mill.

The report of Utah Copper for the second quarter of the year shows a total production of 25,124,052 lb., an average of 8,374,684 per month. The net profits from mining and milling operations were $1,184,199. To this is added $356,428 Nevada Con. dividends and $8352 from miscellaneous sources, making the total income for the quarter $1,548,979. The average cost of production for the quarter was 7.53c. per pound, and for the month of May, when the ore averaged 1.2 lb. better per ton than in the other months, the cost was 7.17c. Mr. Jackling, Utah Copper's manager, denies emphatically that the Amalgamated had bought control of Utah, as recently reported from New York, and states further that he does not know of any attempt on the part of that company to do so. This being the case, some of the recent rumors of a great copper merger receive a setback. The steam-shovel operations of the Utah company have extended well into the town of Upper Bingham, so that the company has been obliged to purchase the ground. Most of the houses have been torn down, and one of the most thickly populated portions has been turned into a waste dump. An eighty-room three-story boarding house is being erected. Seventeen steam-shovels are now at work. Nearly 1000 men are at work on the Bingham & Garfield railroad, and it is expected that all grading and tunnel work will be finished by next spring, so that a year hence the company will be hauling its own ore. The road, which will be laid with 90-lb. steel, has a down grade all the way to the mills, with a maximum of 2.5%. The Copperton plant has been closed, ostensibly to curtail production during the dull period. Production at this plant has always been accomplished at a figure considerably in excess of that at the larger mill, and it is doubtful if operations here will be resumed.

At the Garfield smelter additional reverberatory furnaces and a brick stack that will be 350 ft. high are being erected. The plant now has 3500 tons capacity per day. With the new equipment it will become one of the largest copper smelters in the world. Within a year's time the plant will be outputting at the rate of 16,000,000 lb. of blister copper per month. Meantime at the Tooele smelter of the I. S. & R. another reverberatory has been finished and is ready for warming up. The Utah Consolidated has finished its contract with the Garfield smelter and is delivering to the Tooele plant. It is expected that the Giroux will commence shipping its high-grade ores within about three months' time, and an unconfirmed report from the East is to the effect that the South Utah will also ship to Tooele. This high-grade ore and concentrate will be most acceptable, as, while the Utah Con. ore is a good smelting mixture, the copper content is low. Surprise was caused by the announcement that the Yampa smelter was to close down, and at this writing the last furnace has been blown out. The plant has been a success metallurgically, but the Yampa ore is of low grade, and in order to keep the smelter supplied it was necessary to work the mine to full capacity, which did not permit of selecting the ore. The smelter has been treating about 700 tons per day, but will now ship about 250 tons to the Garfield plant. This smaller tonnage will permit of selecting the ore so that only the better grade need be shipped and the general average kept higher than it has been. Probably a favorable smelting rate was made, as the Yampa ore makes an excellent smelting mixture, being like the Utah Con., which the Garfield plant has just lost. With an improvement in copper prices it is not unreasonable to look for a resumption of operations at the smelter.

One of the most important deals in the history of Park City was put through a few days ago when the Daly-Judge closed a contract by which the Ontario drain tunnel will be extended from its present terminus in Daly West ground to the Anchor shaft of the Daly-Judge. The Daly-Judge has been submerged below the 1600-ft. level for some years, and this will afford relief. The tunnel taps the Daly West at

1550 ft., but will reach the Anchor shaft at 1950 ft. This will allow working certain portions of the mine which are known to be rich, but which have heretofore been inaccessible. Work of extending the tunnel was commenced the day after the contract was signed. It will in no way interfere with the driving of the Snake Creek tunnel to the Daly-Judge, as this will drain and develop a different district. Commencement of this contract has revived rumors of a great consolidation of Park City properties, and S. M. Bamberger, of the Daly West and Ontario, has admitted that consolidation of the Daly West and Ontario is being discussed. Several properties in this district have interests in common and could be operated to advantage under one management, and consolidation is inevitable. The new extension of the tunnel will develop about 700 ft. of virgin ground in the Daly West. This company is considering the building of a new concentrating mill at the mouth of the Ontario tunnel. The matter is being investigated by engineers and will be put up to the directors as soon as their report is ready. The Daly West declared its usual quarterly dividend, but did not include the customary report, as certain returns had not been received. The mine has developed a large tonnage on the 1700 and 1800-ft. levels, but reports are that the assays from these points have been disappointing.

The new pumping plant of the Centennial Eureka should be in operation by the middle of the month or soon after. The plant will be in two units, each with a capacity of 500 gallons per minute, and should be able to handle all of the water for some years to come. The water will be discharged through the Holden tunnel, which taps the shaft at the 550-ft. level. Power for operating the pumps will be generated at a steam-electric plant at the mouth of the tunnel. The Opex is closed for repairs to the hoisting equipment, which should be completed in a week's time. Much indignation has been felt by the public and stockholders at the attitude the management has taken lately in refusing to give out any statement as to conditions in the mine. The recent report of a discovery has been traced to one of the under officials of the company, and it has been assumed that those high up connived at the announcement. The directors held a meeting recently and levied an assessment of three cents per share, but refused to give out any information, even to stockholders. The general impression is that the find was made, but was in Centennial Eureka ground. The stockholders are hoping that a little more prospecting will show that the vein is in the Opex. The Victoria has voted to increase its capital stock from 250,000 to 700,000 shares, the par to remain the same. Stockholders will send in their old stock and receive two shares of the new for one of the old. Of the stock 100,000 shares will be set aside to acquire the Snowflake Mining Co., and 100,000 will remain in the treasury. The Victoria is sinking its shaft to get to the deep orebodies which have been worked through the Grand Central. This necessitates a haul of several thousand feet. The new Hendrie & Bolthoff double-drum hoist ordered for the Eagle & Blue Bell has been delivered and will be ready in two weeks. The new equipment is good for 2000 ft. The shaft has been sunk to the 400-ft. level, while the raise that has been driven from the 1000-ft. to meet it has advanced 100 ft. The Lower Mammoth is centering operations on the 1800-ft. level. Developments on the 2000-ft. level have not been up to expectations. An assessment has been levied to take care of an overdraft at the bank and the stockholders will doubtless be called upon before long to decide as to the future of the mine. The Dragon has commenced sinking its shaft from the 600-ft. level and will continue the work until the 1000 is reached. Experience in the other Tintic mines has proved that good ore is usually found under such iron as the Dragon has on the upper levels, and the company is going deeper in the expectation of encountering it.

The Bullion Coalition at Stockton is extending the old Honerine tunnel, already 12,000 ft. in length. The incline from the 600-ft. level to the surface is also being put in shape. The producer gas-electric plant of the Gold Springs Mining & Power Co. at Modena has been started and is operating successfully. The Jennie mine, which is owned by the same company, is working two shifts at mine and mill. The plant uses 'slack' coal. The tunnel of the Utah Mines Coalition has tapped the old Black Bess vein at a depth of 900 ft., 3000 ft. under cover. The Black Bess was a good producer in the early days, but was given up because of the heavy flow of water. The new tunnel which opens the mine at depth relieves this difficulty. The Wasatch Utah has installed a two-stamp concentration and cyanide plant and is treating ten tons of ore per day. The ore runs $40 to $50 in gold and makes a concentrate averaging close to $200 in gold, with copper and silver in addition.

WASHINGTON

Fire and the Geological Survey.—Alaska Land Claims.—Bureau of Mines.

For the fifth time in the last seven years, the Washington fire department has 'rescued' the priceless records of the Geological Survey from devouring flames. On Sunday afternoon, July 31, they made their latest successful attempt. That is, the last unless another fire breaks out before this reaches the reader. A shoe store, with $30,000 worth of goods, situated on the first floor, lost everything and $1000 damage was done to the Survey library. The story is not true that one of the young women employed at the Survey objected to a fireman coming in with heavy dirty boots. Firemen are always welcome at the home of the Geological Survey and are greeted cordially. In fact, they have attended so many warm functions in the Survey building they know every nook and cranny. This intimate knowledge of the hospitable walls of the building is responsible for the slight loss to the Government. The firemen did not flounder through the dark halls and fall over large jars that are placed at the doors of many rooms. When the chief on the sidewalk shouted, "Jimmie, turn the hose on in the Director's room," Jimmie knew just what was meant. It is feared in some quarters that this latest fire may have a bad effect on Congress this fall. After every fire some eloquent member has discoursed for an hour or more on the danger of a conflagration wiping out the 'millions of dollars worth of records.' This was generally followed by a bill for a new building. Then some other member, who had not thought of the danger in time to make a speech, promptly killed the bill. Last year the Survey building escaped a fire and Congress actually authorized a new building for the Survey, the Bureau of Mines, Reclamation Service, Land Office, and Indian Office, to cost $2,500,000. Enough money was appropriated for drawing plans and it was expected that an appropriation for a real fireproof structure would be forthcoming at the next session. If Congress follows out its usual line of reasoning on this proposition, there will be no money for a new structure. The argument will be that the present building cannot burn. Hasn't it been on fire five times and isn't the building still there? "Let us have a care for the peepul's money in these days of billion-dollar congresses." And so the Survey people may be doomed to remain in the present building for years, with frequent, unexpected little parties attended by the helmeted firemen. George Otis Smith, Director of the Survey, takes another view of the case. He says: "The fire gives emphasis to the wisdom of Congress in authorizing at its last session for the preparation of plans for a government building that will not only be better adapted to the peculiar needs of this scientific and map-making bureau, but will insure the safety of the public records that have been five times endangered by fire destruction since 1903. The loss of government property is thought to be less than $1000, but an incalculable loss might easily have been incurred in the library, which is unique in its collection of geologic literature, containing, as it does, more than 65,000 volumes as well as 85,000 pamphlets and 35,000 maps, and constituting the most complete collection of geological works and maps in this country if not in the world. The destruction of these by fire would have deprived not only the geologists of the Survey, but the scientists of America of a reference collection that could not be duplicated."

An investigation has been ordered to determine the validity of titles of all coal lands in Alaska outside of the Cun-

ningham claims. The latter claims have been subjected to a special investigation and are now awaiting action by the Commissioner of the General Land Office. Andrew Christensen, chief of the field division of the Land Office, will have charge of the investigation. He will endeavor to learn whether the claimants of the coal lands are maintaining good faith and will attempt to cover all the technicalities involved in the titles to the Alaskan coalfields. Among the principal claims which will come under this investigation is the Greene group, comprising 90 entries, and the Harriman group. Mr. Christensen expects to leave for Seattle within a week to establish headquarters. Experts are now in Alaska looking after many details of the investigation. Thousands of acres of unappropriated lands which were eliminated from the national forests and restored to the public domain by recent proclamation of the President, will be thrown open to homestead settlement and entry this fall, according to orders of the Interior Department. The lands are in Colorado, New Mexico, Washington, Oregon, Utah, Idaho, and Wyoming. Appointment of a permanent Director of the Bureau of Mines is still to be made. Mr. Smith has gone to Europe and Mr. Holmes is in the West arranging for the new mine-rescue stations. J. K. Jones, president of the Pittsburg-Buffalo Coal Co., has come out in a strong interview insisting that Mr. Holmes should be appointed, but it is not probable that any change will be made immediately.

NEW YORK

Plight of the Shearers.—Rumors of the Copper Merger or Agreement.—Some Western Coppers.—Price of Copper and Silver.

The low tide of the vacation season has grounded an immense number of the smaller financial craft high up on the mud. The ubiquitous, and always mentioned, oldest inhabitant is insistent in his expression that the present ebb of the financial waters is the lowest within the memory of man. Wall Street is confronted with the one thing it cannot overcome. The big public has its head turned in the other direction, and refuses to look around. One particularly amusing feature of the situation is the cry of the Eastern financial leaders that all the balance of the country has become ruinously extravagant, has taken to automobiles and pianolas to the great detriment of the market. The farmer, never so well to do as just now, has evidently made up his mind that, if any one rides in an automobile purchased with his money, it should be himself—an exhibition of good judgment, that will cause a scarcity of lambs and a light clip in Wall Street and possibly may result in some of the shearing gang having to go to work. With the good roads' movement growing and the exaggerated crop scares out of the way, the farmer, the country banker, and the country merchant, can continue to give their support to the automobile industry directly rather than by way of the stock market. The problem is a serious one for Wall Street, the political situation and the attitude of the public are interwoven. To disarm the prevailing prejudice and at the same time to make a fight politically in behalf of the corporations requires more dexterity than appears available. The bumptious 'show-me' attitude of the West is greatly deplored and just at this time is both annoying and disconcerting. The awakening of the West to its independence is joyful, the later realizations of the East are painful. In mining circles the problem of copper curtailment is foremost, the chief question being the ultimate result of the attempt to cut down production. If copper producers can be aided by a little increased activity among consumers, they may succeed in getting the copper surplus out of the way before the prospect of higher prices brings more production into the market. While none admit any agreement, announcements are made as to the percentage of curtailment, and record-breaking is at an end for a time. Whatever terms may have been agreed upon in the division of the smelting industry and the selling-end of the metal market, the public is evidently not to be taken into confidence, nor is any agreement in restraint of trade to be revealed to the Federal authorities. Since copper mining is to slow down, the first effect of the move will be a turn to the precious metals. Nevada Consolidated, making the cheapest copper in the country—according to statement, 6.34c. per lb. for the quarter ended June 30, and Utah Copper holding a place as the largest single producer, give the A. S. & R. Co. a commanding position. Curtailment at Butte by the Anaconda in June was offset by the activities of some of the newer companies. As a result Butte produced 4,000,000 lb. more copper in July than in June. While there is no talk of copper merger, there are consolidations under way that mean further concentration of management in each instance. The absorption of Gila by the Ray Con. has been almost unnoticed. Now, the consolidation of Calumet & Arizona with the Superior & Pittsburgh, is to give the latter an up-to-date plant and the former an opportunity to use its $3,000,000 surplus in the acquirement and development of the latter's ore reserves. It is probable that the Chemung Copper will be taken into this merger. This property consists of 240 acres in the Burro Mountain district of New Mexico.

The Development Company of America which has been a factor in the exploitation of enterprises in the Southwest, has found it necessary to call upon shareholders to deposit 51% of their holdings with the company, to be used as collateral for a loan with which to aid the subsidiary companies to a paying basis. Among the propositions put out by this company are the Tombstone Con., the Imperial Copper Co., at Silverbell, Arizona, equipped with a smelter and which recently absorbed the El Tiro; the Poland Mining Co. and a new railroad which is to connect the Imperial Copper with tidewater on the Gulf of California. The Imperial Copper Co. has been producing 800,000 lb. of copper monthly, but closed down on account of the low price for copper. The newly acquired territory of the El Tiro has developed 8,000,000 tons of ore, said to run from 2 to 3½% copper.

Thomas L. Livermore, vice-president of the Calumet & Hecla for 21 years, is to retire at the annual meeting, August 17. He presided at the meeting of the Copper Producers' Association for the last time on August 7. His successor has not been chosen. Miami Copper is expected to be producing by January 1. It is said there is a possibility of a small additional stock issue being offered to present holders, which is likely as the plant cost $500,000 more than was anticipated. The copper metal market has responded somewhat to the prospect of a dwindling surplus. Lake Copper is held by the Calumet & Hecla at 13c., while the United Metals Selling Agency reports sales of 100,000,000 lb. at 12½ and 12⅝c. in the last two weeks. This agency has been supporting the metal market and was supposed to have accumulated a heavy load of metal. These sales preclude the possibility of a large surplus in their hands. Of the amount mentioned nearly all went into the stocks of domestic consumers. A recent cave-in at the Granby displaced 100,000 tons of ore. However, the ore can all be mined. Diamond-drill work is being pushed on the Granby; on the 400-ft. level. Granby is claimed to be making money even with its present increased costs, though the management maintains an attitude of silence and shareholders are left to form their own estimates. A. E. Stillwell, one of the prominent figures in the present development of Mexico, has returned to New York, after a four months campaign abroad placing the securities of the Kansas City, Mexico & Orient railway, which is to extend from Kansas City to Topolobampo, Mexico, 1659 miles, of which 878 miles have been completed. Mr. Stillwell has organized subsidiary companies to give attention to the development of the mineral resources along the line.

The silver market during the month showed the highest average price for any month of the year so far—54¼c. Cobalt operators figure this to mean an additional $1,040,000 in dividends for Cobalt, estimating the output of the camp for 1910 at 26,000,000 oz. The shareholders of the Tonopah Belmont have been disappointed at the failure of the directors to announce a definite dividend policy. It is said that the board foresees the necessity of doubling the present capacity of the Belmont mill and for the time it will be necessary to utilize the earnings for that purpose. The 60-stamp mill can handle 200 tons daily.

General Mining News

ALASKA

(Special Correspondence).—Seattle men are examining the Red Wing mine in Ketchikan district and if conditions are favorable will continue the mining and development there.——Several new orebodies of good grade have been struck recently at the Jumbo. Another shipment is being made from this property.——The steamer *Northland* is taking on another shipment from the It mine. All the drifts are in good ore. A diamond-drill has been installed at this property.——J. J. Martin, representing the Chicago Exploration Co., is examining the Unik placers of 6000 acres, with Empire drills. The ground is reported to carry gold from 25c. to 50c. per cu. yd. J. W. Daily has men repairing the wagon-road up the Unuk river for the purpose of transporting machinery and supplies to the mines.—— A small test shipment is being made from Seal Bay by P. Heaney. The tunnel is in 1600 ft. and nine well-defined veins have been cut, some of them carrying good ore.

Ketchikan, August 1.

ARIZONA

The report of the territorial auditor for the year 1909, shows the total value of all mineral products to have been $42,946,745. Under the mine taxation law, taxes are paid on 25% of the output which would be 10,736,686.29.

The following table shows the tonnage of the various metals produced in the territory last year:

Pounds of copper	297,703,301
Ounces of gold	132,278
Ounces of silver	2,352,356
Pounds of lead	2,153,102
Pounds of zinc	6,053,145
Pounds of iron	3,325,347
Pounds of sulphur	553,090
Tons of lime	23,331
Tons of silica	22,589

This was the first year in which the tonnage of lime manufactured was reported.

GILA COUNTY

In the Globe district, the Phelps-Dodge interests employ 500 men above ground and 500 in the mines. Four furnaces are being operated and are making full runs.

MOHAVE COUNTY

The Tom Reed Mining Co., near Goldroad, has recently installed a 16-ton electric motor to drive tube-mills and other machinery.——William Ochs, of Salt Lake City, has closed a deal for the Gold Trail property of A. L. McKesson, near Goldroad.——It is reported that the Tyro mine, in the Union Pass region, will soon be operated by Eastern men represented by W. Harvey Weed, who recently made an examination of the property.——A few days ago the Keystone mine, at Mineral Park, made its first car shipment of ore to the smelter. The ore came from the new workings, and is said to be rich in gold and silver. By the time the shaft reaches a new level the stopes will have been opened in the levels above and the property become a regular shipper. At present all the ore that goes into the shipments is taken from the drifts, the dump ores being shipped by themselves on account of the freight rate.——William and Frank O'Dea have been working on the Pilgrim mines, west of Chloride, and report a body of rich gold ore at the 200-ft. level. The shaft was sunk on ore following the hanging wall and no attention paid to the vein lying below the fault. The owners have run a cross-cut into the foot and found the best body of ore ever seen in the property. Specimens show free gold.

YAVAPAI COUNTY

At the White Cloud mine, near Wickenburg, Edward Casper was killed and Joseph Peruna seriously injured a few days since by the falling of a cross-head a distance of 300 ft. as they were descending the shaft. The cross-head became jammed near the 100-ft. level, and the bucket continued to descend. It finally became loosened when the men were within a few feet of the bottom of the shaft and fell with the result above stated.——Machinery and timbers are daily arriving at the Arkansas & Arizona Copper Co.'s mines in the Jerome district.——At the Hull the 3600-ft. drift is thought to be within a few feet of the vein cut by the 1888 shaft.——At the Jerome-Verde mine the sinking of the main shaft is to be resumed as soon as the water is out.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence).—The Climax mine, near Pine Grove, has been sold to the Gold King Mining & Milling Co. Fredrick A. Stokes, of New York, is heavily interested. The Climax has been developed to a limited extent, but has been idle since 1906. The new owners will promptly commence operations.——The Bunker Hill Co. paid its 49th dividend, amounting to 5c. per share, on July 15, making $80,000 disbursed in profits during the past six months. Most of the ore is coming from the 1750-ft. level where the ore showing is large. It is expected to commence production from the 1950-ft. level within a few months.—— The Argonaut directors have decided to temporarily suspend dividends, chiefly owing to the costs attending the litigation with the Kennedy Extension Co.——The strike recently made in the Central Eureka continues to stimulate interest. Latest advices are to the effect that the ore is showing good value as development progresses.——The Kennedy is pushing development vigorously on the 3300-ft. level, where 12 ft. of ore is being mined.

Forty-Stamp Mill, Argonaut Mining Co., Jackson, California.

Surface Works, Kennedy Extension Mining Co., Jackson, California.

Jackson, August 5.

MADERA COUNTY

It is currently reported that Charles M. Schwab is interested in the development of the great iron deposits in the Minaret district, and that the Guggenheims are also spending money on development of iron at the summit of the Sierra Nevada. The Federal Development Co. has spent more than $20,000 in the district in the exploration of iron deposits. The Noble Electric Steel Co. is laying in a large stock of supplies with the evident intention of working throughout the winter of 1910-11. This company is said to be active in securing power sites in that region, and it is said the Guggenheims are looking into the transportation problem.

MODOC COUNTY

(Special Correspondence).—A discovery is reported from the mine of the Fort Bidwell Con. Co., near Fort Bidwell, where a 9-in. streak averages $170 gold. The discovery

was made under the direction of Algernon Del Mar, the new manager. Some of the ore is extremely rich. The property is equipped with mill and cyanide plant.

Fort Bidwell, August 5.

NEVADA COUNTY

A large barn owned by the Tarr Mining Co., and a dwelling owned by Mrs. James Kelly, of San Francisco, in the Smartsville district, were destroyed by fire last week. This is the second fire that the Tarr Mining Co. has had within the last year. It was supposed to be of incendiary origin. ——Rich ore has been found by C. L. Wilson, who is developing the Black Bear, Metropolitan, and other claims below Moores Flat. Mr. Wilson says that the bonanza ore was taken out of the Black Bear, which is reached through the adit on the Metropolitan. It is the intention to run another adit further down the hill. It is planned to erect a 20-stamp mill on the group, as there is plenty of ore to keep the stamps busy. The district is on the Nevada county side of the Alleghany mineral zone.

PLUMAS COUNTY

The property of Joseph Peppin, consisting of five locations, and the Caldwell group of six, belonging to J. A. Hall, adjoining the Frazier group, have been bonded to the Consolidated M. & M. Co., of Alameda. In the past, both of the properties have been dividend-payers. On the claims owned by Mr. Peppin there is a 10-stamp mill which will be used to sample the ore taken from the two claims. The main adit on the Frazier group, in several hundred feet, will be extended.

TRINITY COUNTY

(Special Correspondence).—It is reported that the Bonanza-King hydro-electric power plant, near Carrville, is to be rebuilt.——The Headlight company will build a bridge across Trinity river at Buckskin Point, south of Carrville, to facilitate the bringing in of supplies during the high-water periods. It will be a 125-ft. single span steel structure, with concrete piers, costing $4000.——Flume construction will begin shortly. Ground has been broken for the power plant and the right-of-way for power-line is being cleared.

Carrville, August 7.

TUOLUMNE COUNTY

(Special Correspondence).—A find was made last week in the Intervenor mine, in the southern part of the county, and being operated by W. H. Remington, and associates. The discovery was made in a drift, where high-grade ore, 4 ft. wide, was opened. t is said a larger force will be employed, and the road to the property repaired, preparatory to hauling in machinery and lumber for buildings.——The company interested in the Fleming mine, at Campo Seco, two miles south of Jamestown, contemplates putting men at work on development. It is reported the management will install machinery.——A lot of machinery has arrived at the Moffit Bridge gravel mine, on the Tuolumne river, including an engine and pumps. Excavating a ditch to divert the river, and other preparatory work was commenced months ago.——Work is in progress at the Jumper mine, near Stent, preparatory to renewing operations on a large scale. The surface improvements contemplated will require $50,000. Among these will be a building for a combined machine and blacksmith shop, several other buildings, and an addition to the mill. The hoist and buildings on sites over the hanging wall are being moved to the foot-wall side of the vein. Re-timbering the Golden Rule shaft and straightening the Jumper shaft is in progress. The Jumper Mining Co. has been reorganized, several of its members, however, having been identified with the former company. ——About 30 men are employed at the Mazeppa mine. The mill is being overhauled and a new track to this plant completed. A crew in the mine is cleaning drifts and stopes and making other preparations for mining. It is said to be the intention to erect a larger mill. The proposed crushing plant will be on Woods creek, several hundred feet distant from the present one.——Development of the Empire mine, on Mormon creek, is progressing and prospects are encouraging. Two ore-cars and 1000 ft. of rails have been purchased for the property.——Mining operations have been discontinued at the Draper, near Soulsbyville, which for the last two years has been worked by Cotton & McCormick, the owners. The pumps are still in operation, but whether mining will be resumed by the same operators cannot be learned.——Additional men have been put to work at the Black Oak mine re-timbering the shaft, which will be sunk another 100 ft. It is reported that work has been resumed at the Basin mine, south of Confidence.——The work of extending the drift on the 400-ft. level of the Dutch mine, at Quartz, to connect that property with the Sweeney, is in progress.——The suit of John Daves *v.* Frank Daves, et al., involving ownership of the Basin Chief mine, in Basin district, has been decided in favor of plaintiff. Litigation commenced soon after a rich find was made a few months ago, when ore assaying from a few dollars to $1000 per ton, was uncovered.

Tuolumne, August 5.

COLORADO

During July, the five largest mining districts of the State, Leadville, Cripple Creek, San Juan, Ouray, and Clear Creek, shipped nearly $2,000,000, Cripple Creek alone outputting $1,224,935, and Ouray, $275,000.

CLEAR CREEK COUNTY

(Special Correspondence).—During the past ten days 150 miners and prospectors have gone into the new goldfield at Beshears.——An electric drill has arrived for the Reliance Gold Mines Corporation. A transmission line is being run to connect with the United Hydro P. & E. Co. line.——The Ruler mine on Griffith mountain, has been leased by Charles Roland, of Syracuse, N. Y. Work will begin by September 1. N. Williams will be manager.——F. Nelson, manager for the Bard Creek M. Co., has bought a Leyner compressor and drills.——G. J. Hite has sold the Spanish claims on Columbia mountain to S. D. Sigafoos, and others, of Denver.——The Scotia mill at Silver Plume is running steadily and a large tonnage of lead and zinc concentrate is being finished.——Machinery has been bought for driving of the lower adit on the Gambetta property, on Republican mountain.——Larger shipments are being made by the Banner Con. M. Co., to the North American S. & M. Co. ——F. Seroy has discovered mica in Squirrel gulch. The sheets are from 12 to 18 in. square.——Machine-drills are running at the face of the Oneida adit at Freeland. A streak of ore 18 in. wide in the breast assays $60 per ton gold and silver.——The Holland adit at Lamartine is in 700 ft. and going ahead.——Ore 30 in. wide has been cut in the east drift of the Kentuck, operated through the Central adit.——A pump that will handle 50 gal. per minute is being placed in the Clifford mine up Fall river.

Georgetown, August 6.

GILPIN COUNTY

(Special Correspondence).—A number of small veins and stringers of ore have been penetrated in the Newhouse tunnel since the south vein of the Gunnell group was reached. Within 30 days the heading will have passed through the entire Gunnell holdings.——A compressor and machine drills have been installed at the Blue Bell mine. The shaft is down 300 ft., but will be sunk 200 ft. deeper.——The Cumberland M. Co. has started shipments. Tests show from $400 to $600 per ton in gold and silver.——Shipments are also being made from the West Whiting mine on Gunnell hill, to the Star mill for concentration. Smelter shipments return $60 per ton in gold.——The new machinery at the General Jackson mine is in operation.——The shaft on the British mine, down 220 ft., is to be sunk 200 ft. more. The new machinery is running.

Central City, August 6.

LAKE COUNTY

During July the mines of Leadville shipped 70,000 tons of ore. Never since the early days of the district have there been so many new shafts sinking as at present. This activity extends from the vicinity of Prospect mountain, on the north, to beyond Iowa gulch on the south, and from the Mosquito range to Sugar Loaf. There is unusual activity upon the Mosquito range both on the Leadville side and on the Park county side.

TELLER COUNTY

The ontput of the Cripple Creek district for July was 51,821 tons, valued at $1,224,935, which was a small decrease from the production of June, attributed to the closing of important mines from July 3 to 5. Although a greater number of mines were in operation during the latter days of the month than usual.

Following are the figures of monthly treatment at mills and smelters:

	Tons Treated.	Average Value.	Gross Value.
Smelters	3,600	$65.50	$235,800.00
Golden Cycle Mill	24,520	19.40	475,688.00
U. S. R. & R. Co.	12,000	22.00	275,688.00
Portland G. M. Co.	10,000	20.00	200,000.00
Portland New Mill	8,643	3.32	28,694.76
Gaylord Mill	1,600	4.00	6,400.00
Wild H. Mill	958	3.50	3,353.00
Totals	51,821		$1,224,935.76

IDAHO

SHOSHONE COUNTY

(Special Correspondence).—Reports by the management at the annual meeting of shareholders of the Snowstorm Mining Co., at Larson, show the mining and shipping of 91,308 tons of ore during the year ended June 30, 1910, the average value of which was 6.908 oz. silver, and 4.067% copper per ton. The silver was marketed at an average of 52.208c. per oz., and the copper at 12.954c. per lb. The receipts from all sources, including a surplus of $46,402.45, and the estimated value of ore in transit, amounted to $507,473.29. Operating expenses and exploration and improvements cost $264,210.68. The dividends paid during the year amounted to $179,940, with a surplus of $63,322.61 on July 1.

It is reported the Reindeer mine near Mullen is to become one of the steadlest producers in the Coeur d'Alene district. The Reindeer has large ore reserves, and with a crusher and hand jigs the ore can be concentrated to a percentage of copper that will justify shipping. Ore production can be started on a small scale, and gradually increased.

Development is being done on the Rex mine, formerly the 16 to 1, three miles from Wallace, worked under lease by the Silver-Lead company. There is an abundance of ore blocked out and a mill is being put into shape to handle a large production. It will be ready inside of 60 days. The largest quantity of the ore lies below the 3200-ft. tunnel. From the tunnel a 600-ft. shaft has been sunk on the ore-body, and the shoot has been opened at all the levels from that. Forty men are working on the mill and in the mine.

Caledonia Mining company, operating in the Coeur d'Alene, announces that it will stop dividends for some time, now that the original stockholders have received their money back. All income from shipments will be used in running a tunnel, to put in a mill, and generally developing the mine. It is said that the reduction in cost of handling ore by a lower tunnel will be at least $2 per ton. Meanwhile, the production of 1000 tons per month is to be kept up.

Work has been resumed on the Original Ajax Mining Co.'s property on Nine Mile creek, near Wallace, after a shutdown of six months. A contract has been awarded for 150 ft. of driving on the lode, though the owners expect to get under the ore-shoot inside of 100 ft. J. W. Gilson, one of the owners, says the ore runs up to $18 per ton, mostly in silver. Work is being pushed from the lower tunnel, which cut the lode at a distance of 276 ft., but no driving to the ore was done at the time.

Spokane, August 3.

MISSOURI

JASPER COUNTY

Morris & Co., operating a hand-jig in the Kansas City bottoms on the new Union depot site, made a turn-in last week of 3150 lb. of dry-bone to the Picher Lead Co., the ore being worth $32 per ton. Previous turn-ins of dry-bone, or low-grade lead, have been made from the Union depot property since the work of excavation was started. The hand jiggers secure their rights to mine the ore from Jenkins & Jennings, who have the contract for the excavation of the Union depot site. The ore is found at shallow levels in the vicinity of former mining operations. The percentage of ore in the dirt sluiced is small, but owing to the light expense of washing it the product can be handled at a profit.

MONTANA

BROADWATER COUNTY

(Special Correspondence).—The Keating Gold Mining Co., at Radersburg, has a new electric plant and is working satisfactorily. A favorable smelting agreement has been made with the East Butte Copper Co., and regular shipments are being made to that smelter. The ore averages $19.20 in gold.

Radersburg, August 4.

SILVER BOW COUNTY

(Special Correspondence).—Officers of the Anaconda company at Butte still insist that no policy of curtailment of copper production has been put into effect in Butte, and that, so far as they know, none will be. However, the July production was 5,000,000 lb. below the normal output of the Butte district. The normal average for some years has been 28,000,000 lb. per month. The production of the Clark smelter has been entirely eliminated by the closing of that plant. The Great Falls smelter of the Anaconda company, which has been producing in excess of 8,000,000 lb. has dropped under 7,000,000, but the Washoe smelter, handling all of the Anaconda, Butte Coalition, North Butte, and Clark mine ores, has not reduced its production. John D. Ryan is expected in Butte shortly. It is understood among Western copper men that an agreement to curtail production was reached at the London conference, and is being put in force gradually. In addition to the curtailment in Butte, it is announced that Calumet & Hecla, Utah Copper, Nevada Consolidated, and the Phelps-Dodge interests in this country, and Rio Tinto and other European producers will act in line with the London agreement. J. P. Morgan, and his associated financiers, are the real power behind the copper curtailment movement; they recognize that an unsettled copper market has had a pernicious effect on the general business interests.

The Butte Central Copper Co. is driving on the Ophir south vein on the 500-ft. level with encouraging results. Shipments will be made to Denver and Salt Lake to determine the character of mill that will be necessary for treating it, as it is the purpose of the company to erect a concentrator as soon as that question is settled.

The East Butte Copper Mining Co. is running its smelter chiefly on custom ore. The East Butte instead of mining its own ore during the low metal market, is accepting all the custom ore offered and reserves its own ore until copper is higher. In view of the fact that the East Butte company has been making a monthly profit for more than a year, the company has violated the laws of the State by neglecting or refusing to make a report to the authorities as to operating expenses and net profits. All other operating companies in the district have complied with the law.

Butte, August 7.

NEVADA

CLARK COUNTY

(Special Correspondence).—The water supply of the Quartette company has increased and the mill is again operating at full capacity. Good ore is being developed in the lower level.——The Eldorado Crown has purchased a cyanide plant. The mill has been treating considerable ore, and the tailing often runs as high as $15 per ton. Most of this will be recovered by cyanide.——The Pompeii company announces that it will resume milling.——The Santa Fe has recently encountered several bunches of rich quartz, and plans the installation of pumps and the sinking of the shaft.——The Chief of the Hills lease has installed a gasoline hoist and is opening good ore.——The shaft of the New York-Searchlight is being placed in first-class shape

and equipped with new guides. As soon as the new machinery is in place the shaft will be sunk to 500 ft.——The Gold Star company will install a gasoline hoist. This company is entirely composed of negroes.——The Lirigo Mining & Milling Co. has been organized to operate a group of gold, silver, and tungsten properties at Camp Signal. J. F. Main is general manager.——The Monte Cristo company has also been organized to mine in this district.

Searchlight, August 3.

STOREY COUNTY

(Special Correspondence).—Fire in the top works of the Belcher mine at Gold Hill this afternoon completely destroyed the plant, and did some damage to timber-sets in the upper portion of the shaft. No one was injured, as the men had left the mine a short time before. Damage is estimated at over $25,000.

Virginia City, August 9.

Development at the north-end mines on the Comstock continues favorable, with an improvement on the 2400-ft. level of Mexican. In Ophir the 2000-ft. level will give about the same extraction of ore from the understope in the southwest drift. On the 2300 in the raise started last week the ore continues, and is of good grade. On the 2400 in the southwest drift, sill floor sets are being put in. In the Mexican in the north drift from the east cross-cut a streak of ore on the east side was cut giving good assays. The ore is widening and assays show improvement.

The pumping operations are being advanced as rapidly as possible at the C. & C. shaft. It is thought that it will require at least two more lowerings of the big hydraulic lift in order to pump the shaft out to the sump at the 2650. That the end is in sight is indicated by the fact that the water being raised now is filled with muck and is very dirty. Thus far it is being readily handled by the pumps. In a short time it will be possible to go into the 2650 station.

There is no change of note in Con. Virginia, the stoping of low-grade ore from the 1750 and 1800 levels being under way as usual. At the Hale & Norcross ore of good grade is being stoped and the first shipment to the mill was hoisted through the C. & C. shaft a few days ago.

NYE COUNTY

(Special Correspondence).—A large force is employed building foundations for the compressors, hoist, and ore-bins at the Belmont shaft. The shaft has been enlarged to 3 compartments to within 240 ft. of the surface, and it is expected to finish it within two months. The main vein has been opened for nearly 700 ft. on its strike, and 400 ft. on the dip. It has an average width of 15 ft.——A diamond-drill at the 800-ft. station of MacNamara will drill a down-hole 1000 ft. to prospect the formation. No attempt is being made to develop the recently intersected vein.——The south cross-cut from the 270-ft. level of Tonopah Extension has intersected the vein and shows 5 ft. of milling ore. The west foot-wall drift from the 400-ft. level is progressing rapidly and is expected to connect with the old west workings within a few days.——The Montana-Tonopah is continuing to make semi-monthly shipments of bullion valued at approximately $16,000. The mill is operating steadily, treating 990 tons per week.——The Transvaal of Nevada mine, near Rhyolite, has been leased by C. S. Coleman, of Los Angeles, and a small crew put at work. The vein on the 50-ft. level is being prospected.——Lessees on the Diamond are opening a 2-ft. vein averaging $10 to $35 per ton. A recent shipment of 30 tons was made to the Murray smelter. The ore is being mined on the 300-ft. level. ——The Shively & Bennett lease, and the Gingles & Vucovich lease on Tramp Con., report streaks of rich ore several inches wide. In the latter lease the rich part is 6 in. wide and consists of white quartz.——The warring factions of the Manhattan Dexter have adjusted their troubles, and a new company, independent of the Dexter, will be formed to operate all the leases.

Tonopah, August 6.

WHITE PINE COUNTY

(Special Correspondence).—W. A. Clark says he has no present intention of building a branch of his Salt Lake railroad into the Ely district. He admits that the matter has been talked about, and that even a survey has been made, but aside from that nothing has been done, and for the present nothing will be done. The road would be used chiefly to transport ore from the Giroux mines to the Tooele smelter of the International Smelting & Refining Co., and it is understood that the International interests will be associated with Mr. Clark in the building and ownership of the road.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence).—The management of the Socorro mines has decided to install another Harvey-Steele tilting furnace, the present equipment being inadequate owing to the increased production. This week 1400 lb. of refined gold and silver was cast into bars weighing 100 lb. each. The vein on the 600 west has widened to 12 ft. The width is 23 ft. where last cross-cut on 600 east. This, the lowest level, is furnishing the best average grade ore coming from the mine.——The Ernestine mine and mill are in full operation.——Lumber for the mill at the Deadwood mines is being delivered as rapidly as possible. Grading is well under way. Considerable building material is loaded out from Silver City and should arrive during the week. Construction will be pushed as fast as deliveries will permit. ——Arrangements have been perfected whereby work will be started on the various holdings of the Mogollon G. & C. Co. within 60 days.——In addition to the work in the main tunnel of the Enterprise Mining Co., a winze has been started in the second level.

Mogollon, August 5.

UTAH

BEAVER COUNTY

The Frisco Consolidated Mining Co., owning property on what is supposed to be an extension to the Hornsilver vein, is about to begin prospecting extensively. Already 1500 ft. of development has been done. In one of the prospect shafts 30 in. of good ore was found at a depth of 130 ft. The ore carried argentiferous lead to the value of $50 per ton.

WASHINGTON

STEVENS COUNTY

(Special Correspondence).—Fires in and around the Deertrail mines have destroyed considerable valuable mining timber. The bunk-house and post-office building at Deertrail were destroyed and fire is raging in the vicinity of the Seal and Queen mines, and near Germania tungsten mines, which is two miles distant from the Queen. There are 75 men working at the tungsten property, part of whom are fighting the fires.

FERRY COUNTY

(Special Correspondence).—Robert Maboy, Thomas A. White, L. W. Anderson, J. W. Lloyd, and others, have leased and bonded the Knob Hill and Mud Lake claims, at the head of Eureka gulch, in Republic camp. The Knob Hill was worked for 12 years and has produced some good ore. The lessees are opening that claim from the east side of the hill and have driven from a 35-ft. cross-cut adit 25 ft. on a vein from 3 to 4 ft. 8 in. wide and are getting ore which assays $146 per ton across the widest part, and some assaying as high as $300 per ton. About 40 tons of ore are ready for shipment. A new cross-cut adit, now in 60 ft., will be driven 180 ft. to the vein at a vertical depth of 200 and 300 ft. on the dip. The lessees will shortly incorporate. Fourteen men are employed on three shifts. ——The Pacific Ore Co. has partly completed the frame work of a 100-ton cyanide mill at Republic. When finished the mill will have four floors. The ore-bin will have a capacity of 125 tons. A Gates crusher, three Chilean mills, with feeders, and an automatic sampler will be among the equipment.——The lessees of the North San Poil mine have drifted from the turnsheet in the lower San Poil adit 455 ft., following the vein the most of that distance. The drift is getting into the pay-shoot, which shows some very good ore.——A large tonnage of iron sulphide will be shipped

from the Copper Key mine as soon as the Spokane Falls & Northern railway completes a spur from the mouth of Lambert creek.

CANADA

BRITISH COLUMBIA

The report of the Minister of Mines, of the Province of British Columbia, states that the production for the year ended December 31 last amounted to $24,443,025, an increase over the preceding year of $591,748. The total tonnage was over 2,057,713 tons, the mines of the Phoenix district contributing about 50% of this.

The ore shipments from Rossland district for the week ended July 30, and for the year, to that date, were as follows:

	Tons	
	Week.	Year.
Centre Star group	3,560	111,392
Le Roi	470	8,628
Le Roi 2, Ltd. (part conc.)	540	17,889
Velvet	31	245

Rossland, August 6.

The production of metal at the Trail smelter and refinery of the Consolidated Mining & Smelting Co. of Canada, Limited, was $5,911,767 for the year ended June 30, 1910. This was an increase over the preceding year of over $400,000. The following table shows the production for the year, including the month of June:

	June.	Year.
Gold	$248,321	$2,814,676
Silver	76,890	1,134,881
Copper	63,608	779,230
Lead	102,211	1,182,980
	$491,030	$5,911,767

Ore shipments from Phoenix and the Boundary district for the week ended July 30, and for the year, to that date, were as follows:

	Tons	
	Week.	Year.
Granby group	20,721	712,213
Jackpot	679	3,901
Mother Lode	6,800	200,300
Oro, Denoro	289	7,375
Snowshoe	2,130	102,717

Phoenix, August 1.

The shipments of ore and concentrate from the Slocan-Kootenay district for the week ended July 30, and for the year to that date for the mines named, were as indicated in the following table:

	Tons	
	Week.	Year.
Eastmount	35	485
Emerald	29	1,124
Queen (conc.)	39	383
Queen Victoria	138	2,046
Richmond-Eureka	31	2,539
St. Eugene (conc.)	191	9,773
Sullivan	288	7,690
Yankee Girl	129	3,249
District milling	5,000	158,000

Slocan, August 1.

ONTARIO

On the 100-ft. level in the northwest cross-cut, 20 ft. from No. 1 vein, the Temiskaming & Hudson Bay Co. has struck a new vein that recalls memories of the first days in Cobalt when silver was picked up off the ground. Never in the history of this mine, which holds the dividend record of the camp, has such ore been found underground. The new vein is 10 in. wide and is well over 50% silver by weight. A poor sample that did not contain so much free silver was shipped out for assaying and went over 6000 oz. per ton. The find is 20 ft. in the cross-cut beyond No. 1, which was an 18-in. vein of 4000-oz. ore. From the cross-cut 101 bags of very rich ore was taken. The drift has been driven 20 ft. on it and it holds good. To date this company has paid $166 on every dollar invested, or 16,600 per cent.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

S. J. Speak is in Australia.

S. H. Ball has gone to Siberia.

S. S. Howe has gone to Montana.

W. H. Weed was in San Francisco.

C. R. McCollom is in San Francisco.

Whitman Symmes has been in San Francisco.

Ralph Aanold was in San Francisco this week.

Sumner S. Smith is in Shasta county, California.

A. G. Cadogan is now at Mina Boston, Costa Rica.

E. B. Webster is now at Vancouver, British Columbia.

H. Van Manning is chief clerk of the U. S. Bureau of Mines.

C. W. Hayes is expected in Los Angeles, returning from Mexico.

F. W. Bradley has returned to San Francisco from Alaska.

Donald Steel, of Ithaca, N. Y., will spend a couple of years in Africa.

Bertram Hunt has gone to the Jewel mine, Greenwood, British Columbia.

Francis Drake is out of the hospital and has gone to Boyes Springs, California.

Ross B. Hoffmann returned from British Columbia and has gone to Denver, Colorado.

J. A. Holmes is organizing the work of the new rescue stations of the U. S. Bureau of Mines.

E. A. Jackson is vice-president and general manager for the North California Mining Company.

O. H. Packer has returned from the Minaret mountains, where he has been examining iron ore deposits.

F. D. Baker is chief engineer of the Colorado Department of the American Smelting & Refining Company.

R. S. Handy is now superintendent of the concentrating mills of the Bunker Hill & Sullivan M. & C. Co., Kellogg, Idaho.

George S. Rice has declined a proffered position with the T. C. I. & R. Co. and will remain with the U. S. Bureau of Mines.

C. T. Durell will sail from Victoria, August 17, for the Far East. He is to be manager for the Headwaters Mining Co., Baguio, P. I.

A. H. Brooks sailed from Seattle, August 8, for Alaska. He will go to Matanuska coalfield and later will visit the mining districts of southeastern Alaska.

Clifton H. Wildman has resigned as manager for the Morning & Evening Star M. & M. Co., at Ward, Colorado, and gone to Norwalk, Ohio, to recuperate from a severe attack of rheumatism.

George Otis Smith has gone to Stockholm, Sweden, to attend the meeting of the International Geological Congress, August 18 to 25. Other representatives of the Geological Survey will be Waldemar Lindgren, George F. Becker, S. F. Emmons, and Whitman Cross.

OBITUARY

George Riley, Sr., who was one of those killed in the railway wreck near Ignacio, California, August 8, was well known to the mining profession, having been connected with the business department of various technical papers on the Pacific Coast. He had but recently severed his connection with the *Pacific Rural Press*. Mr. Riley was 55 years of age at the time of his death. He leaves a widow and two children, George Riley, Jr., and Mrs. Robert N. Lynch, to whom will go the sympathy of a widely scattered circle of friends among mining men and machinery manufacturers.

GOLDFIELD CONSOLIDATED FOR JULY

Following is the preliminary report of operations of the Goldfield Con. Mines Co., for July, 1910, as submitted by J. R. Finlay, general manager:

TONNAGE PRODUCED

	Wet Tons.	Dry Tons.	Ounces per Ton.	Gross Value.
Combination	5,250	4,858	1.13	$113,124
Mohawk	7,664	7,092	1.16	169,545
Red Top	3,999	3,700	1.56	119,288
Clermont	6,652	6,155	3.38	428,677
Total	23,565	21,805	1.84	$830,634

The performance of the mill was as follows:

Dry tons milled	21,805
Value per ton (average)	$38.10
Total value	$830,634
Loss in tailing	$49,619
Total realized	$781,015
Percentage extracted	94.03

General expense—	Amount.	Average per Ton.
Bullion tax and marketing bullion...	$15,000	
Administration, etc.	17,000	
	$32,000	$1.47
Mining	80,000	3.67
Transportation	2,800	0.13
Milling and cyaniding.....$55,200		
Marketing concentrate residues 12,000	67,200	3.08
Construction	25,000	1.15
Net cost	207,000	9.50
Loss in tailing	49,619	2.28
Total costs and losses	$256,619	$11.78

Profit per ton, $26.32; total value of ore, $38.10; total profit, $574,015; total profit, percentage, 69.11.

Operations were hampered in July by shortage of water for milling. The mine and mill were both ready by July to continue production at full capacity, but during the month the water received was only two-thirds that available in March. By using the spent cyanide solutions in the batteries instead of fresh water, it was possible to get through about 85% of a full tonnage, but this practice is not metallurgically good. Both costs and losses were increased over what they should bave been. Discoveries of new ore were few during the month. The total advance in development was 2520 ft. New ore was taken from main levels as follows:

	Level.	Tons.	Oz.
Combination	230	200	0.75
Mohawk	450	90	1.87
Clermont	600	405	0.60
Red Top	750	270	0.75
		965	0.97

COPPER PRODUCERS ASSOCIATION FIGURES

The monthly report of the Copper Producers' Association, made public August 8, shows copper stocks on hand August 1 were 170,640,678 lb., as against 168,386,017 July 1, an increase of 2,255,661. July production was 118,370,003, as compared with 127,219,188 in June, a decrease of 8,849,185 lb. Total deliveries in July were 116,115,342, as compared with 119,259,144 in June, a decrease of 3,143,802 lb. Of the deliveries, 56,708,175 lb. were for domestic consumption and 59,407,167 were for export, domestic deliveries showing an increase of 3,344,979, while deliveries for export decreased 6,488,781 pounds.

EDITORIAL

THE COLONEL, it seems, cannot come to Los Angeles to attend the Mining Congress. All we have to say to that is that he is going to miss "a perfectly corking good time."

THE date of the dinner of the Mining and Metallurgical Society at Los Angeles has been changed to September 29. An excursion along the line of the aqueduct is also planned. Mr. Seeley W. Mudd is in charge of arrangements.

DIAMOND prospecting in Rhodesia is expected to be stimulated by the action of the courts in confirming the validity of the agreement entered into in 1892 between the Chartered Company of South Africa and the De Beers Company. Under this agreement the latter was granted a license to work all diamantiferous deposits in both north and south Rhodesia. Confirmation of this grant will, it is thought, result in the finding of new diamond fields.

THROUGH train service on the new Western Pacific railway is to be established August 22, and the event is to be properly celebrated by a number of California cities. The new railway line will have advantages in competition in the matter of low grades, and has been built most substantially. With completion of improvements planned for its Eastern connection, the Denver & Rio Grande, it will become an important factor in the freight situation of the West. As a tourist route, it is assured of popularity from the start.

PROMPTNESS in publishing reports is not characteristic of Government Bureaus. By some method not known to his fellow workers, Mr. Willet G. Miller, provincial geologist of Ontario, has frequently found means to overcome the difficulties and to issue reports and maps at the time they were most needed. Another instance of his enterprise is evidenced in the abstract we present elsewhere, of a report on the Porcupine district, just published. The report and map have been issued less than three months after the beginning of the field work, yet no one familiar with Mr. Miller's work at Cobalt and elsewhere will doubt the accuracy and value of the report. The latter, while brief, as befits an advance statement, is sure to be as helpful as it is welcome. Tennessee as well as Ontario is enjoying the benefits of prompt publication of geological survey results. Mr. G. H. Ashley is already distributing Bulletins 1 and 3 of the new State Geological Survey, and excellent bulletins they are. We hope such commendable enterprise may stimulate others to like promptness.

ANNOUNCEMENT was made some months since that a merger of the mines along the Comstock Lode in Nevada was about to be accomplished. The plans of the projectors, however, fell through. One curious phase of the matter was that stocks fell rather than rose when the merger was announced. There is no question that under strong engineering and financial management the prospects for mining would be greatly improved. In 'Comstocks,' however, there has long been no very direct relation between mine and certificate, and under the proposed consolidation, the opportunity for 'rigging the market' would be materially lessened. The value of the shares to speculative holders therefore fell, and much stock was dumped on the market rather than deposited under agreement. The one thing San Franciscans did not want, was a consolidation that would limit speculation. The reform administration of the City did away with slot machines, and the people remained passive; but to interfere with time honored manipulation of Comstocks, was going too far. On the other hand, the New Yorkers seemed willing enough to assume management, but not to buy stock. The net result has been a considerable change in ownership which still, however, remains largely in San Francisco. Efforts are being made to bring existing companies close together and to effect needed reforms at the mines and on Bush street. How successful these will prove is uncertain.

STAMPS are again doomed to extinction. Mr. Mark R. Lamb, in an interesting and thoughtful paper presented to the American Institute of Mining Engineers, argues that the days of the gravity stamp in cyanide plants are numbered, and calls attention to the frequent disposition to substitute cyanidation for amalgamation even when rich free-milling ore is treated. Between steam-stamps for crushing large tonnages, and rolls for smaller amounts, the field of the gravity stamp is undoubtedly being narrowed. The development of steam-stamps suitable for moderate tonnages, a step already over long delayed, and the undoubted tendency to use stamps more as crushing and less as amalgamating devices, will still further limit their use. The gravity stamp, however, when it is at all usable, is so simple, effective, and adaptable, it is so well understood, demurrage with it is so small (relatively), and salvage in reconstruction so large, that it will always remain the great stand-by of the gold miner. There are some machines so simple that they are incapable of much improvement, and they hold their own against later, and in many respects superior, devices. Steam is powerful in ocean transportation, but sailing vessels still carry much cargo, and the shape and position of sails change little with the passage of centuries. Hoisting engines of increasing complexity and efficiency are built, but the homely windlass and simple horse-whim are as widely used as ever. A cordial welcome will be extended to the new steam-stamp and the best of good wishes go out to the perfecters of rolls, but we shall expect nevertheless to be soothed to sleep many a night by the welcome roar of the stamps.

TURKEY is attracting attention among European mining engineers and investors, and the question has been raised as to why Americans have not entered the field. The Ottoman Empire undoubtedly includes much undeveloped territory in which important mineral resources exist. Foreign capital and technical skill will be needed to convert the existing prospects into mines. Many of those who have lived in Asia Minor have high respect for the Turks as individuals, but their bad government has become a by-word. Under the present regime great improvement is to be expected, but the country is old and the people are conservative. An American mining engineer finds his way beset with difficulties not met at home or in Mexico, and so long as good opportunities remain open in North America our participation in Near-Eastern affairs is apt to be slight. With the profits won at home and the experience and money acquired in Mexico, Americans will more probably interest themselves in South America when nearer fields become crowded.

Foreign Trade and Ownership

With remarkable regularity, the always interesting *Daily Consular and Trade Reports* lectures American manufacturers and exporters on their failure to improve opportunities for foreign trade. We are so accustomed to hearing of our short-comings in the matter that we would be quite cast down except that even a limited acquaintance with the subject reveals the fact that English and German manufacturers and exporters come in for the same lectures from their Consuls and expatriated critics. After having been thoroughly convinced that the crass stupidity of our own merchants has lost us magnificent commercial opportunities in Korea and Manchuria, to the great gain of those of Great Britain, it is disconcerting to read in the letters of English travelers, how British trade in the Orient is being steadily displaced by the shrewd Yankees and ubiquitous Germans. It is scarcely less discomfiting after having become finally reconciled to our complete extinction before the Teutonic advance, to hear the mournful wail that comes from the Vaterland to the effect that 'the knell of German shipping in the East has been sounded by the Japanese.' Many Japanese steamers, it happens, are built with British capital, and the International Mercantile Marine is dominated by an American house. When much ado is made over the inroads of the Germans in sales of electric machinery in South Africa, it is well to remember that the Allgemeine Elektricitats Gesellschaft and the General Electric Company do not sound very different when translated into the same language. The truth is that international trade is itself international. No nation may expect a permanent monopoly and trade cannot be long maintained along artificial lines. If we would sell, we must expect to buy. At times direct exchange is feasible and profitable. At other times an indirect course brings better returns. In any event the profits are widely distributed and the ownership of a boat is by no means determined by the flag it flies as is quickly learned at the sea coast.

BY THE WAY

In the course of his Commencement Address at Madison, Wisconsin, Mr. C. R. Van Hise, president of the University, gave the following deffinition of the relations between the University and the State:

The strength of the State University lies in its close relations to the State. The State demands service; the University feels a peculiar obligation. It is the duty of the State University to instruct young men and women; it is its duty to advance knowledge, and especially those lines of knowledge which concern the development of the State. It is the duty of the staff of the State University to be at the service of the State along all lines in which their expert knowledge will be helpful; it is their duty to assist in carrying knowledge to the people. These relations between the University and the State bind them closely together. The growth of the University is dependent upon the State. The State owns the University; and every citizen feels himself to be a stockholder in that ownership. But associated with these close relations, which are the strength of the State University, are also its most serious dangers. These are that the University may be politically controlled, and that it may be hampered in its work.

To the first of these dangers the State University is especially exposed in its youth. It speaks well for the democracy of this country that as the States have developed, the danger of political interference in university government has steadily become less.

The other danger of the close association of the University with the State—interference with its work—has two aspects; first, it may be demanded that the teaching which looks toward material ends shall be strong, while the humanities are allowed to remain weak or not properly developed, and second, freedom of teaching and investigation may be interfered with. The former is probably the more imminent danger for the majority of institutions. It is natural, indeed inevitable, that the people shall demand that effective teaching, research, and extension of knowledge shall be done in agriculture, in engineering, and in other lines from which a financial return may be shown from the investment. These demands are right and should be fully met by the University; but also the people should appreciate that all material gains are for men and women. Why do we wish to produce more wheat and cotton? In order that human beings may be fed and clothed. But, "The life is more than meat and the body is more than raiment." Shall the people demand of their University that it provide for their material needs and neglect the people themselves—their intellectual, artistic, moral, and spiritual development? The capacity of a State University to make the man himself, as a subject of study and advancement, maintain a paramount position will be the crucial test of the State University. The University authorities must insist that man shall not become subordinate to material gain. If the people will support a State University in which these ideals obtain, then can it be truly said that a democracy is a success.

The remaining danger of the close association of the State with the University is the possibility of interference with the freedom of teaching and investigation. If such interference occurs, it is likely to be indirect rather than direct, and is therefore all the more insidious. A sentiment may be developed or a situation may arise in a State such that the professor feels he is not free to teach the truth as he sees it; and to quote a phrase, he may feel that he must 'shade the truth' somewhat.

For my own part, I have no doubt that in all the States in which the State Universities are strongly established the overwhelming majority of the people are in favor of absolute freedom of teaching and investigation. But frequently the deep-seated dominant sentiment does not express itself, and there are always some who would place limitations upon the field of a University. But a University must insist that the whole domain of physical and human phenomena belong within its scope—pure science, applied science, politics, morals, religion, are proper fields of study. In making this statement I do not mean to imply that the State University should dogmatize; but this is no more true of politics and religion than it is of agriculture. In no field should the method of the University be that of dogmatic teaching. The facts concerning any subject should be broadly dealt with; none should be hidden; their bearings should be considered with reference to the principles which flow from them; and always without bias. The attitude of the professor in reference to every subject should be that of a candid judge, not that of an advocate, but an absolutely free and fearless judge who feels heavily the responsibility of his position of trust. Shall the University be free to teach that a certain practice in agriculture is wrong and advocate a new and improved practice, and the same principle not apply in politics and in morals? Such a position would be intolerable. No institution which does not handle the humanities in all their amplifications under the same principles that it handles the pure and applied sciences is worthy of the name of a University.

In taking part in the work of advancement of the State, the staff of the University should be free from intellectual arrogance and devoid of any attempt to force their ideas upon the people. If the State gives freedom of teaching and investigation to the University staff, also the people of the State should be free to accept or reject as their judgment may dictate. It is by the free contest of ideas and ideals, often widely diverging, that progress is made. It is self-evident that no man or group of men have the right to assume that they have a monopoly of truth. The staff of a University, above most groups of men, should recognize the complexity of the facts, the impossibility of arriving at the absolute, and so without fear and without bias, with firmness, but with profound humility, present their ideas to the world to be accepted if found good and to be rejected if found inadequate. It is incumbent that the Universities play their part in leadership. Times of unrest, of changing ideas and ideals, are above all, the times when the Universities should be most effective in the guidance of public opinion.

Top-Slicing Mining Methods at Cananea, Mexico

By Courtenay De Kalb

Many different methods are employed in mining at Cananea, owing to the varied characters of the orebodies. One of the most interesting is the adaptation of top-slicing in the Oversight mine, belonging to the Cananea Consolidated Copper Mining Co. Every application of caving systems of mining is in effect an adaptation to local conditions. The details

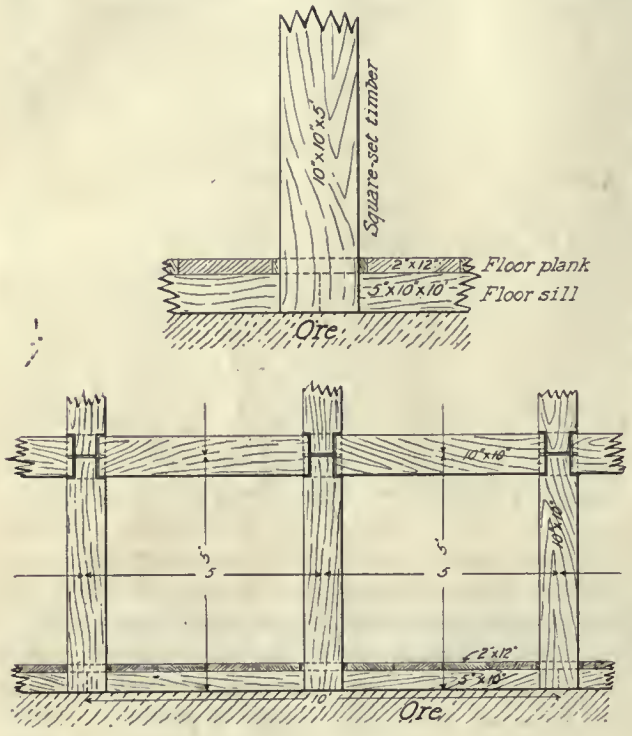

Fig. 1.

as developed at one property will not serve the needs at another without modification. The adaptation made at the Oversight by James Kirk, superintendent of mines, in collaboration with his brother, Harry E. Kirk, possesses some interesting features. The orebody is of quite irregular outline, its horizontal cross-section bearing some resemblance to the imprint of a bare foot upon the soil. The overburden, leached and highly altered, but having a tendency to settle in part as large unbroken blocks, varies from 150 to 900 ft. in thickness, and the outer rims of the orebody, locally termed 'shore-lines,' range from 75 to 500 ft. apart, horizontally. To a limited extent only are temporary chutes or ore-mills maintained for working the ore downward. Where many raises are driven the ground is thereby weakened, and the chutes must be placed so as to assist in the self-crushing of the ore-masses as they cave; in other words, they must be correlated with the method of mining. This would disarrange the top-slicing system. The temporary chutes are here never closer than 30 ft. The main chutes are of a relatively permanent character, leading to loading-bins on certain levels, whence the ore is hoisted to the surface.

The main levels are 100 ft. apart vertically, and the main haulage levels are at still greater intervals. For slicing, a series of intermediate levels are driven 10 ft. apart vertically, and the ground is further subdivided by parallel intermediate levels and by cross-cuts, approximately 50 ft. apart horizontally. The orebody is primarily explored by main longitudinal drifts, and by occasional cross-cuts, after which a contour-level, along the 'shore-line,' is advanced: and approximately parallel but straighter sub-levels block out the ground for slicing. Where the orebody is narrow a sub-level is driven along the longitudinal axis of the mass, and 'subs' are extended parallel to this at a convenient distance inside the wall or 'shore-line' to admit of shoveling the ore into cars from either direction, otherwise only half the value

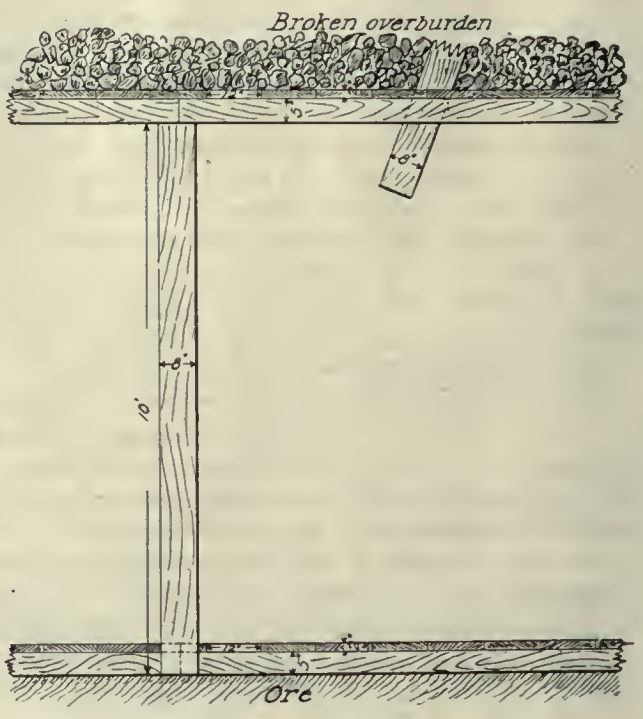

Fig. 2.

of the 'sub,' as a way for transportation, would be realized.

In starting work at a new point beneath the overburden, its irregularities need to be reduced to a plane for the successful application of top-slicing. This is achieved by mining out the necessary amount down to a feasible horizon by the square-set method.

Fig. 3.

The posts, however, do not stand upon sills. If the ore beneath is exceptionally soft the posts rest on foot-plates. Sills are laid only to catch the flooring, the ends of the boards abutting along the centre lines of these sills. The object is to permit the burden to sink, but to maintain a good floor to prevent a spill. The burden will drive the posts below the floor-line as the ground beneath is mined, while the new posts set below hold up the floor-sills, and thus

preserve a quite regular and safe roof under which mining may be continued. This principle is persisted in throughout, and it has also proved economical of timber. The posts or stulls used in top-slicing consist of Texas round pine, 8 by 10 in., costing 80c. delivered. The floor-plank are 2 by 12 in. by 10 ft. long, and the floor-sills are 5 by 10 in. by 16 ft. long. It will be seen that less timber is used where the plank abut on a 5 by 10-in. sill than where they are made to overlap, shingle-fashion, as is commonly done. The sill not only economizes, so far as the overlap is concerned, but it takes the place of the head-plates required in the other system when catching up the floor from beneath. The method is shown in Fig. 1, which illustrates the square-set system, and also the manner of placing the sills and flooring ready for the slice below. The manner of catching up the floor-sill overhead is depicted in Fig. 2, which furthermore shows a stull or post being forced under its load through the upper floor into the space left by the succeeding slice below. The progress of slicing in successive steps is illustrated in Fig 3, where it is seen that the slices advance with faces 50 ft apart, receding from the rim or 'shore-line' of the deposit. The timber consumed by this method amounts to 13 ft. board measure per ton of ore extracted. Before top-slicing was introduced the consumption was 26 ft. The powder used in the Oversight mine averages 1 lb. per ton of output, and the labor efficiency shows 2.7 tons of ore hoisted per man employed.

GOLD MINING IN ALASKA, 1909

*Gold placer and lode mining in Alaska in 1909 showed marked progress in production as well as in preparation for larger operations. The production of gold was about $20,463,000, an increase of $1,170,182 (about 6%), over the output of 1908 and the largest yield since 1906, the year of greatest production.

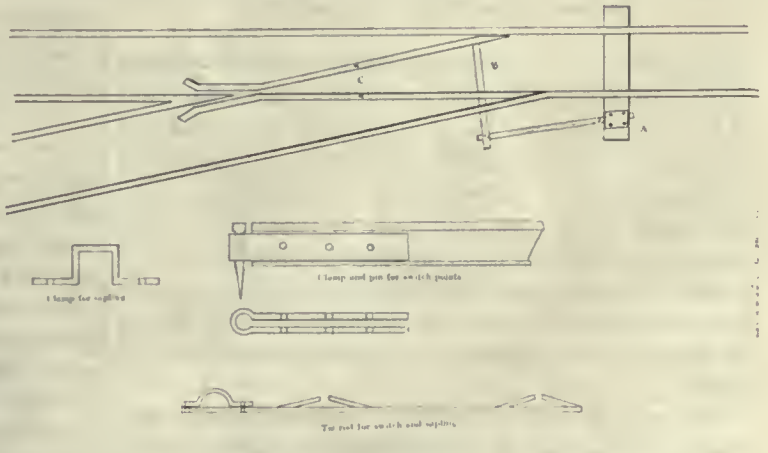
The placer production was $16,322,000; the lode production, including gold derived from copper ores, was $4,107,363. The figures representing the product of the same kinds of mining in 1908 were $15,888,000 and $3,357,335. The Yukon placers yielded their largest annual output in 1909. Practically all the Yukon camps made increased production, those of the Tanana valley leading with about $10,150,000. Of this amount the Fairbanks district produced $9,650,000. A further increase of production is recorded for the Koyukuk district and an important feature of the year's mining was the continued success of dredging in the Fortymile district. All the placer camps were prosperous except those of Seward Peninsula, where dry weather curtailed the output. In this region the methods of mining must evidently be adapted to meet the exigencies due to frequent seasons of low water. Important advances were made in dredging enterprises. The discovery of gold placers on Otter creek, a northern tributary of Iditarod river, in the Innoko valley, caused a movement of population in 1909 which promises to be important. Although the district may not support the large population it has acquired it seems to offer a promising field for exploitation. The output of the year in the Innoko is variously estimated at $300,000 to $400,000. During 1909 Alaska's auriferous lode mines produced gold valued at $4,107,363, an increase of $749,928 over the product of 1908 and the largest annual lode output yet recorded.

*Abstract from Bulletin 442, U. S. Geol. Survey.

A CHEAP AND EFFICIENT SPRING-SWITCH

By S. Clarke

A cheap and efficient spring-switch suitable for wyes and passing tracks, can be made by any blacksmith at a small cost. The dimensions given in the figure below can be changed to suit conditions. The tie to which the sapling is fastened should be about 6 by 8 in. and placed 2 ft. 6 in. beyond the switch points. A hickory sapling, or any wood that is tough and springy, answers the purpose of a spring. The sapling should be 3 ft. 6 in. long and about 2½ in. diam. at the butt. Square the large end to 2 inches in order to make a snug fit in the clamp. The clamp is made of 4 by 6 by ⅜-in. iron bent in the shape shown. Set the clamp at a slight angle from the outer rail in order to get the sapling in a strain, lag-screw or spike the clamp to the tie. The switch points are connected to the frog leads by straps made of 2 by 16 by ¼-in. iron doubled to 8 in., with the end rounded enough to take a ¾-in. pin. The king-pin is 5 in. long and the head ¾ in. square, or nearly large enough to fill the space between the switch points and frog leads. The strap is bolted with ⅜-in. bolts, or riveted. The switch-rod for sapling and switch points is made of ¼ by 1½-in. iron, and forged as shown, with slots welded on to hold the points in place. The sapling is fastened to the end of the rod by a semi-circular collar 1½ in. diam., and bolted to the end of the rod with two

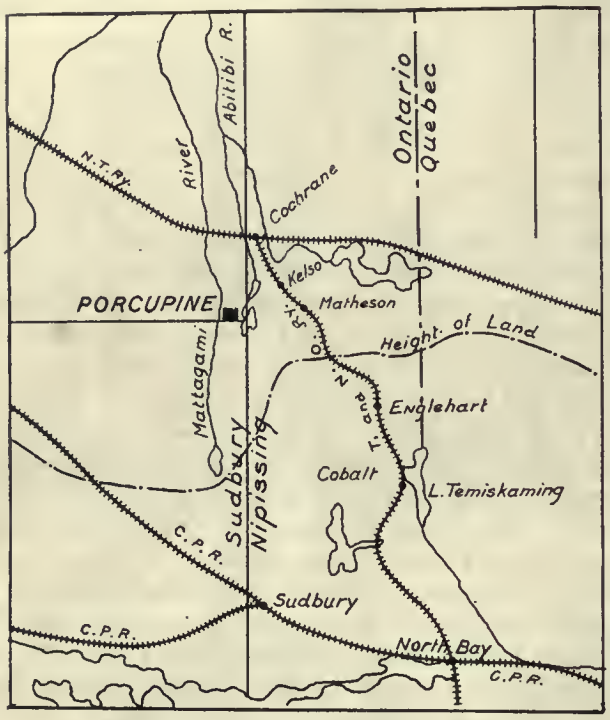


⅜-in. bolts. As the 'spring' of sapling is not always uniform, it is nearly impossible to give the distance that the sapling should be placed from the rail to get the best results. With straight flawless hickory it has been found that if the centre of the tie-clamp be placed 8½ in. from the fixed rail, and the collar on the switch-rod be placed the same distance from the switch points, the spring will work satisfactorily.

Porcupine District of Ontario

By Willet G. Miller

*The geological work which is summarized on this map was done in parts of the months of May and June, 1910. The map has been published as soon as the engravers could complete it. Doubtless errors have been made in the field work, but it was thought best to publish the geological map, imperfect though it may be, at an early period in the camp's development, rather than to wait until it would be of less service. Much of the area mapped is drift-covered and, upon the map, the drift is left uncolored. It entails more work to map an area such as this than one where the outcrops of rock are more continuous. It is not to be expected that all of the outcrops have been located, since many of them are small in size and occur here and there over a low, more or less swampy and densely wooded, surface. Moreover, the extreme eastern and the extreme western parts of the area, bordering on Night Hawk lake and the Mattagami river respectively, have not as yet been mapped in detail. During the present summer the geological field work will be extended and a new enlarged edition of the map will be published next winter. No attempt has been made to put all the names of the mining claims on the map. The names of several of the best-known working properties are shown.



Map Showing Location of Porcupine District.

Outcrops of quartz are very numerous in the area mapped. They are found both in rocks of Keewatin and Huronian age. The age of the rock, whether Keewatin or Huronian, does not appear to have any bearing on the character of the vein, either as to form or as to gold content. While the field work has not extended over a large enough area to include the granite mentioned above, I have little doubt that the quartz deposits of the Porcupine area are connected with the great granite intrusions which took place in post-Lower Huronian times. The quartz has been deposited from the impure waters, highly heated and under great pressure, which worked through the rocks after the granite intrusion.

At the time the field work in connection with the preparation of this map was in progress, development of the orebodies was only in preliminary stages, and facilities for the study of ore deposits were naturally not good. Moreover, it may be said that our object was to prepare a map for the use of the prospectors and to make a more detailed study of the orebodies later on. The detailed maps of Messrs. Knight and Burrows, which accompany this general geological map, show the occurrence of some of the important orebodies. It is seen, for instance, that the orebodies at the Timmins cut across the strike of the schist, and that they vary considerably in width from point to point. This is characteristic of practically all the orebodies in the area. They widen into large masses of quartz, in one or two cases from 75 to 100 ft. in width, and narrow abruptly. Mr. Knight, in the notes published with his detailed plan, refers to this, and compares this abrupt change to that which is frequently seen in granite pegmatite. The Foster vein, mentioned above, differs from the quartz veins or deposits to which reference has just been made. At the end of June there was one shaft down to a depth of approximately 100 ft. A number of others had reached a depth of only about half of this. Time did not permit of our sampling any of the orebodies, and moreover it is not the business of this Bureau to undertake sampling except in rare instances. It could be seen, however, in hand specimens that the quartz in several of the deposits is high grade. Moreover, the writer knows, that so far as systematic sampling has gone, the results are considered to be satisfactory. Of course experienced gold-mining men will not lay too much stress on surface assay values.

Transportation facilities up to the present have been poor, and it is surprising that as much progress has been made as is shown on some of the properties. The Timmins property is well equipped with plant and camp buildings. The plant consists of two boilers of 50 hp. capacity, a 6-drill compressor, hoist, and other equipment. A 2-stamp Tremaine mill is to be erected for sampling. The Dome mines have a somewhat similar plant to that of the Timmins. A Nissen stamp, now on the ground, is to be erected for sampling. Other properties with plants are the Bannerman and the Crown Charter. While conditions of travel from the railway to Porcupine during the spring were not good, it will be a not unpleasant trip during the summer. Good accommodations are available at the hotel and boarding houses at Porcupine lake. Transportation facilities are being increased. Before autumn the route from the railway will, it is believed, be much improved.

*Abstract from legend of a map prepared by Mr. Miller and published by the Department of Lands, Forests, and Mines of Ontario, August 16. The map itself is on the scale of one mile to the inch and is accompanied by two large scale-sheets showing the quartz veins on the Timmins, Dome, and Foster properties.

Standardization of English in Technical Literature

By T. A. Rickard

*It should not be necessary to apologize for submitting the consideration of this subject. Whether my views prove acceptable or not is a small matter; my aim in addressing you is to engage your interest in matters not alien to the purpose for which this Institution was organized: to direct your attention to the intelligent use of words in technical writing. Whether you agree with my views on the subject is of no vital consequence if only, by arousing your critical faculty, you may be induced to use in a thoughtful way words and phrases that you now employ thoughtlessly, or, shall I say, habitually, without having taken the trouble to consider the fundamental principles involved. Let us agree to disagree, if you will, but let us unite in performing an important part of our professional work in a scientific manner, as becomes technical men.

"Science and literature are not two things, but two sides of one thing." So said Huxley, and he illustrated his own saying until his writings became as glimpses of the obvious and his lectures as windows into the infinite. We need to be reminded occasionally that science is not divorced from literature, and that even technology is not compelled to go about as if legally separated from good English.

As technical men we are always ready to lay stress on the necessity for precision, yet when we come to record the observations and conclusions gathered and formed during a laborious career we are apt to use the first verbal implements at hand, instead of chiseling our speech with the tools given to us by the masters of language. As well try to cut a statue out of marble with a dull adze as to express scientific ideas by aid of colloquial words, local terms, and vulgar idioms; as well paint a sunset with a scrubbing brush.

The purpose of language is to convey ideas; the intent of technical writing is to transfer accurate information, whether as fact or theory, from one man to another to the gain of all. Indeed, the benefit is usually more to the giver than to the receiver. In the exchange of ideas it is particularly true that it is more blessed to give than to receive. No man learns so much from the writing of a book or an article as the author himself. It has been well said that if you want to learn all about a subject, write a book on it. At the start the writer finds his knowledge as full of holes as a sieve and his thoughts as turbid as the pulp from a stamp-mill. In the effort to convey information by writing he crystallizes the amorphous ideas collected during years of study and observation; he submits the confused notions in his brain to the settling process of logical thinking, whereby the true is precipitated from the false, the accurate is decanted from the inaccurate, the fact is filtered from the supposition, and, finally, the solution of speech, pellucid but enriched, is outpoured generously.

The value of such a performance, either to the author or to his readers, depends upon the manner of it. There be those that write on a subject only helplessly to obscure, only hopelessly to obfuscate, only stupidly to mislead. Even men possessing individual experience or exceptional knowledge may fail in conveying either the one or the other, because they make careless use of the medium employed.

A notion used to prevail, and still survives, that nicety in the use of words is in a practical man almost effeminate. To some people the effort to write correctly is deemed an affectation, as if it were not as essential to the comprehension of the long-suffering reader as to the understanding of the author himself, whose ideas are clarified by using a correct medium of speech.

The turbid pulp in a mill is made clear by passing through classifiers and settlers. Not until a technical man sits down and begins honestly to tell what he knows on any given subject does he find how hazy is his information, and if he indulge in vague generalities, careless terms, and involved idioms, he never will render himself or his ideas clear either to himself or to his readers. Thus, an intelligent use of the medium of written speech is self-discipline, to which every serious worker ought to submit himself at regular intervals as a measure of efficiency and a stimulus to betterment.

Huxley said that Spencer's idea of tragedy was a theory killed by a fact; my idea of the tragic is the vast amount of useful information that is lost by being unrecorded. What enormous quantities of notes, the embryonic beginnings of scientific literature, remain undeveloped and are finally cast into the fire! It may be that some of them are better fitted to light the hearth than to fire the imagination, but at least I would have them sifted and sorted, if haply they may contain nuggets of information or gems of thought. Every year some mining engineer or metallurgist dies leaving a bulky collection of notes useless to anyone but himself, and useless at last even to himself; such notes may relate to unique observations or individual experience, the record of which would be as stepping-stones to those that follow.

In some cases the expectation has been to complete the study of a subject before rushing into print. As if anything were complete in this transitory world! Nothing is more pathetic than the expectation of saying the last word on a subject. It never will be said. The best we can do is to contribute our little all as a mite to the great legacy of knowledge, and then hope to merit an epitaph like John Richard Green's: "He died learning."

The amount of information at first-hand possessed by any man is pitiably small; we are all hopelessly in debt to others—to our contemporaries, to our forefathers, to the race. Yet each man possesses some little bit of knowledge, whether as observation, theory, or experience, that is his very own. Thus each can contribute something to the general fund; and seeing how much he owes it is asking but little that he give cheerfully what he can.

*Abstract of paper read before the Institution of Mining and Metallurgy, London, on May 26, 1910.

Of course, narrow minds still continue to fondle the mean belief that to give information gratuitously is to throw away a stock-in-trade, and that to keep secret the professional or technical experience of a life is to possess an added weapon in the arena of industry. But this is a pitiable fallacy, scarcely worthy of castigation. If adopted universally we would be today as the Hottentot or the Eskimo. Civilization has been evolved by the free exchange of thought and the frank transmission of experience. Whether we be advocates of free trade, fair trade, or reciprocity in matters of national industry, let us at least reject the shriveling policy of protection as applied to the world-wide traffic in ideas.

Science is organized common sense; technology is the precise expression of special knowledge. The ordinary information of an average man is like a pile of firewood, disorderly and bulky; the fund of useful information possessed by the technical man is like an orderly arrangement of fuel in definite lengths, arranged so as to be easily measured and readily available. The result is due to intelligent effort; it is not accident.

"The development of the mind is an advance from the indefinite to the definite." The technical man in his processes, whether of the mill and smelter or in the reducing operations of his mind, follows a similar line of progress. His constant effort is to distinguish between what he knows and what he thinks he knows, between fact and fancy, between observation at first-hand and information at second-hand. And when he comes to place himself on record he should follow an identical course, but with a difference. In his technical operations he deals in the main with insentient matter; in his technical writing he must keep in mind the human element, for he is writing not on stones to be placed in a desert, but on paper to be read by his fellows.

To be effective, sympathy is needed as well as knowledge, otherwise the effort will be sterile. Spencer, who studied style as an adjunct to philosophy, has said: "The good instructor is one in whom nature or discipline has produced what we may call intellectual sympathy—such an insight into another's mental state as is needed rightly to adjust the sequence of ideas to be communicated." In other words, **remember the reader!**

Every writer may not care to pose as an instructor, but in effect every serious writer does instruct to useful purpose, according as he renders himself receptive to the reader, by employing words in a convincing and agreeable manner. "Those are the most effective modes of expression which absorb the smallest amount of the recipient's attention in interpreting the symbols of thought, leaving the greatest amount for the thought itself." So Spencer said. This is the first principle of writing: economy of mental effort. Put yourself in the reader's place. If you do, sincerely and honestly, you will succeed in avoiding all the grosser errors of style and expression that prevent language from becoming pictorial, that hinder the transfer of ideas, and retard the transport of thought.

In technology, as in science generally, the tendency exists to employ impressive words as the symbols of vague ideas instead of using plain speech to express definite notions. Thus we have that comfortable word 'metamorphism' and that weak word 'dynamic.' In economic geology, the phrase 'secondary enrichment' is often used when the phenomena may indicate primary impoverishment. We use the word 'phenomenon' itself as if it stood for something definite. It means an unexplained 'appearance.' When we do not know what a thing is, we call it a 'phenomenon.'

Macaulay said: "I have often observed that a fine Greek compound is an excellent substitute for a reason." We use sonorous multisyllables like 'the chunk of old red standstone' that was thrown by one of the disputants in the row that disrupted the society upon the Stanislaus, as related by Bret Harte.

Apart from the failure to convey information, the use of impressive terms often entails a failure on the part of the writer to understand himself. It is easier to refer to a 'phenomenon' than to explain it, to impute to 'metamorphism' the thermal and physical changes that are seen as through a glass darkly, and to debit 'secondary enrichment' with vagaries in ore distribution that elude the comprehension of the mining engineer. Here again self-discipline should precede the attempt to teach.

Permit me to quote Samuel Johnson: "To explain requires the use of terms less abstruse than that which is to be explained, and such terms cannot always be found. For as nothing can be proved but by supposing something intuitively known, and evident without proof, so nothing can be defined but by the use of words too plain to admit of definition." Lest this sententious dictum should intimidate you, I quote another saying of the great lexicographer: "There is for every thought a certain nice adaptation of words which none other could equal, and which, when a man has been so fortunate as to hit, he has attained in that particular case the perfection of language."

While objecting to the reckless use of local terms and mere vulgarisms, I hope to escape the charge of pedantry. Of course, it is possible to cramp the use of language by too much self-consciousness, by the priggishness of a pedagogue or the pettiness of a pedant. My objection is not to the thoughtful use occasionally of local terms, or even slang, if thereby the meaning of the writer is made clearer, but to the thoughtless and unintelligent adoption of corrupt forms of speech. I do not object to the use of an unscholarly word or an unfamiliar idiom, if either of these is adopted deliberately in order to express ideas not to be appreciated when clothed in conventional terms; but I do protest against blunders arising from mere lack of care and to wilful ignorance of the simplest rules regulating the effective employment of language as a vehicle of thought.

You will remember Macaulay's pleasant correspondence with Napier, the editor of the *Edinburgh Review*. Napier had objected to the use of phrases that were flippant and words that were colloquial. Macaulay vindicated himself by referring to the practice of Addison, "the model of pure and graceful writing," arguing that a little levity of style was

occasionally desirable as a relief from continued earnestness and dignity. He went on to say: "The first rule of all writing—that rule to which every other is subordinate—is that the words used by the writer shall be such as most fully and precisely convey his meaning to the great body of his readers. All considerations about the purity and dignity of style ought to bend to this consideration." And it is safe to say that Macaulay himself did not find it necessary to sacrifice the extraordinarily high level of his style to the attainment of expression or to lucidity of thought.

If those who use the wretched vulgarisms and careless colloquialisms that disfigure so much of technical literature can find in Macaulay's plea for flexibility any warrant for their sins, they are welcome to the solace, but I fail to see any likeness between the intentional levity or reasoned laxity of a careful writer and the unintentional blunders or thoughtless errors of a careless scribbler.

We do not need to become as self-conscious as the centipede, of whom it is related, that he managed to get on well enough until one day he became aware of his hundred feet, so that he tripped and fell by the wayside in a hopeless tangle. Nor, in transferring thought from ourselves to others by means of the vehicle of language, need we imitate the reckless driver who blunders into all the ruts, over all the stones, into all the puddles, and ends by taking the wrong turning, so that his load of fodder never reaches its intended destination, but is scattered in a disorderly mess over the roads of half a county.

The language used in technical writing may be likened to the food we eat. One man says that he wants plain cooking; he does not care for highly-seasoned dishes, and rich entrées disgust him. Another has a delicate palate; he objects to mere chunks of meat and plain boiled vegetables; he asks for something daintier and more appetizing. As a matter of fact, so-called plain food easily degenerates into what the American calls 'hash'; it may be so tasteless and sodden as to be palatable only to a hungry man, while on the other hand the rich sauce and delicate *garniture* soon pall to the satiety of *toujours perdrix*.

In writing as in cooking, in the intellectual as in the physical nourishment, it is necessary to avoid extremes and keep in mind the purpose of the performance. The ideal is good food well cooked and judiciously seasoned, neither so crude as to be unpalatable nor so elaborate as to cloy the taste.

Further, in literature as in gastronomy, the purveyor of nourishment will recognize the necessity for adapting his products to the taste of those whom he desires to please or to strengthen, varying his viands accordingly. Writers who start with the idea of naturalness and simplicity of literary manner are apt to deprecate the tricky allurements of the stylist until they themselves write uncouthly, and may take such pains not to be florid as to become merely bucolic. Their counterpart is the writer who obtains so much enjoyment when weaving words as to forget the object in view, and is so particular as to the manner as to overlook the matter. Both errors of extreme can be cured by paying attention to the fundamental rule: **Remember the reader!** When you cook, remember who is to eat the meat. A *mousse de volaille* would disgust a bricklayer, but a plate of pork and beans might nauseate a bishop.

So, gentlemen, I have felt warranted in trespassing upon your courtesy. I deem myself justified in calling your attention to a subject that seems at first sight only academic, but is in truth as practical as any other appertaining to the work of the engineer. Next to doing things is the ability to state clearly how they are done; next to the possession of useful knowledge is the power to impart it to others.

Men are known by their deeds, but more men are known by their writings; the deed is forgotten, the writing remains. We judge the men we have not met by the letters, reports, and other writings emanating from them. There is an acquaintance wider than that of personal contact, and more intellectual than that of the dinner table.

To a young engineer the ability to write tersely and clearly is an accomplishment that makes him favorably known to those in authority. Many a youngster has obtained the chance of promotion because he compiled his routine reports so that they were instinct with intelligence instead of being dead bundles of words. This is only reasonable, for a crisp and clear manner of writing can come only from vigor and lucidity of thought, such as indicate the efficiency for which the engineer continually strives.

Until you meet a man you judge him by his letters: until you have seen the work of a technical man you judge him by his reports. Therefore, I urge the younger supporters of the Institution, particularly the students, to give heed to this function of the engineer. The older members may be past hope, for the proverb says that you cannot teach new tricks to an old dog, and in any case I do not expect my contemporaries to accept my views as authoritative. But to the younger men I can appeal with the enthusiasm of reform and with the conviction of experience, beseeching them to give heed to a matter the practical importance of which is undeniable, and the neglect of which is a serious blemish upon a profession that should combine the precision of the technologist with the liberality of the scholar.

Dikes and sills of mica-peridotite and pyroxene-lamprophyre occurs in western Kentucky and southern Illinois, and have been recently described by F. J. Fohs. Mica-peridotite occurs on both sides of the Ohio river, while the pyroxene-lamprophyre has been found in Illinois only. The former is characterized by olivene, the latter by a colorless augite. The mica common to both is largely phlogopite and occurs in phenocrysts or laths in a dark green compact ground-mass. The rocks run 34% silica, which indicates their extreme basicity. Little or no feldspar occurs in them; apatite, magnetite, ilmenite, and perofskite are among the accessory minerals. The rock, for the most part, is found greatly altered. It weathers to a soft green and finally to a golden-yellow micaceous clay. Serpentine, calcite, pyrite, and other minerals are among the alteration products. The dikes, with one or two exceptions, strike northwest.

Gold Mining in Korea, 1910

By J. D. Hubbard

A matter of twenty years ago, it became possible for Americans to obtain concessions and exploit the gold deposits of Korea. At present American mining concessions have assumed large proportions, and the total amount of bullion produced per year from quartz and placer properties amounts to over four million dollars. Korea, although about the same size as California, has a wide mineral belt and almost untouched natural resources. The old system of 'squeeze' practised by officials on the poor native, precluded any ambition for riches, as the latter brought only torture and imprisonment until the coin was given up. Consequently the 'Hermit Kingdom,' with the exception of a few worked-out placers, presents an exceptional field for exploitation by experienced mining men. It is a poor place for speculators.

In the early nineties C. W. Morse obtained the whole province of Unsan, in northern Korea, as a mining concession, with full power to develop all mineral in it, and with almost sovereign rights over the native population. This concession was obtained from the Emperor of Korea through Mr. Allen, the United States Minister. Mr. Morse soon sold out to Leigh Hunt who financed the great Oriental Consolidated Mining Co. in an able way. The capital was placed at five millions, which was a bold thing to do then, but time has proved this amount to be conservative. Mr. Hunt partly developed the concession and then sold out the majority of his holdings, having cut, as some thought, the heads off the asparagus. Events have proved that the root and stalk were full of vitality and many new heads have grown since. The Oriental Consolidated is unquestionably the greatest mining company in the whole Orient, including Japan, Siberia, Manchuria, China, and India, with the possible exception of the Mysore mines at Kolar. The company has 240 stamps dropping on ore at the present date, distributed as follows: Tabowie 80, Taracol 80, Kuk San Dong 40, Maibong 30, Candlestick 10. For the fiscal year ended July 1, 1909, there were crushed 296,417 tons of ore, the average value per ton being $5.79 and the total assay value $1,716,104. The bullion produced was $1,438,342. The ore reserves at that time were estimated as follows:

Mine.	Tons.	Value.
Tabowie	339,182	$1,591,041
Taracol	175,000	875,000
Chintui	58,000	232,000
Kuk San Dong	132,000	372,225
Charalowie	29,100	165,200
East Candlestick	600	8,400
Total	733,882	$3,243,866

The total operating cost for the year was $798,424 and the total operating profit $639,918. The amount put back into new construction and development was $83,548, leaving the net receipt for the year over all expenditures $556,370. The report for the fiscal year ended July 1, 1910, is not yet out, but the figures are all a little higher than the preceding year even, while the ore reserves have largely increased.

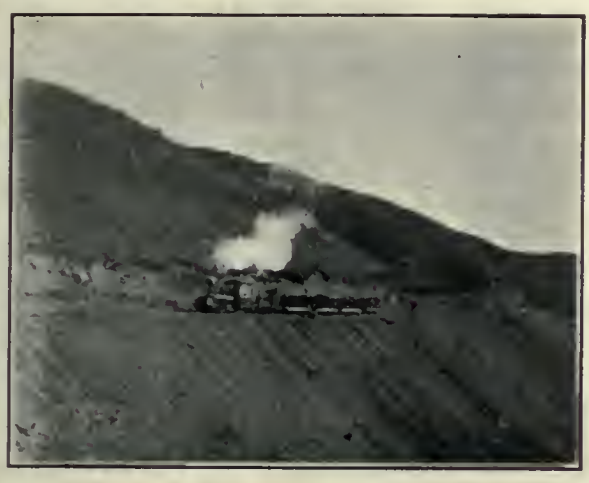
The O. C. M. Co. boasts five mines that have produced over one million dollars each, and soon Chintui will rank as sixth. The company supports a population of at least 50,000 people, and has made the province of Unsan the most prosperous of any in Korea, and the markets are second only to those of Seoul, the capital. The company hospital at Taracol has had the largest attendance for the past two years of any in Korea. This is due to the generous policy of making no charge for services or medicine, and due no less to the excellent system and results obtained by J. W. Nolan, the physician in charge. For the fiscal year ended July 1, 1909, there were 15,652 cases treated, 7878 of that number being company employees. The total cost was $6706.71. The past year over 16,000 cases were treated and medicine furnished for 20,000 people at a total cost of $7500. It is impossible to measure the great boon the Taracol hospital confers on the Korean, whose own medical practice, if it could be called such, is abominable. The Koreans themselves say that where four people died before, but one dies now.

At Taracol are also the company's main machine, blacksmith, and carpenter shops, the foundry, and planing mill, all equipped with good modern machinery. W. H. Aldridge is master mechanic in charge, and in such an odd corner of the world, his ingenuity is often taxed severely by the many demands made upon the shops. This ranges from putting new wicks in lamps and repairing baby carriages, repairing automobile boilers, etc., to building mine pumps and hoists. The big cyanide plant is also at Taracol, and this is the headquarters of the metallurgical department. For the past three years over 84% actual extraction has been obtained by direct leaching of the concentrate in cyanide solution. The company is now preparing to install a modern plant in order to obtain an even better extraction. A. E. Drucker has been appointed as special consulting metallurgist to plan and put in operation this new plant: an excellent appointment. In the matter of the past extractions at the O. C. M. Co.'s plants, an opinion seems to obtain among mining men that they have been low, the methods ancient: but over 84% actual extraction is probably rarer than many suppose. There are at least a few mining companies of which I know, and which are supposed to be up to date, whose actual extractions are below 75%. Even in Korea, it will be hard to make the old dumps pay a profit with a modern plant. Fresh concentrate from a new mill will be different.

The company has a very good system of prospecting, which has been generally adopted by the other mining companies in Korea. Natives are given leases and encouraged to bring in tribute ore to the mills. They are paid 40% of the assay value and in case of low-grade ores only a nominal milling charge is made, that the Korean tributer may not be discouraged. When a good vein is found it is taken over by the company at the expiration of the tributer's lease, and a proper plant installed. The latest prospect taken over by the O. C. M. Co. is at Char-

rongue, 17 miles from Taracol. This is a fine prospect and will probably develop into another good mine. The vein is 15 ft. wide on the surface, assays $3, and has an excellent surface showing for over 2000 feet.

The O. C. M. Co. has had its troubles like all big companies. About two years ago cordwood and mine timbers became scarce as the visible supply on the concession was about exhausted. The nearest supply was six miles from the big camps, Taracol and Tabowie. H. F. Meserve, at that time general manager, made an agreement with the Japanese Forestry Service, whereby upon payment of an annual tax of $12,500 the company could cut all the wood and timbers necessary for the mines from the forests in Chosan province. To make this timber available a railroad, eleven miles long, was constructed at a cost of $50,000 to haul the wood and timbers to a point convenient to the mines. The investment has proved a good one. The company allows natives to ride free on the trains and even transports free of charge their personal belongings. J. N. Fletcher is the general freight, traffic, and passenger agent of this unique railroad. The O. C. M. Co. has a long life ahead of it, and is easily one of the world's greatest gold mines. Alf. Welhaven is now general manager in Korea.



Pakadong Railroad

Tunnel on Pakadong Railroad.

The second American gold mine of importance in Korea is the Seoul Mining Co., at Suon, in Hwang Hai province. The concession covers an area of ground 20 by 13 miles, and the company has exclusive mineral rights to examine, develop, and operate all mines and deposits, for a period of 35 years from 1905. The regular royalty of one per cent on the gross output is paid to the Government. Collbran & Bostwick were the original owners of this concession, and still retain a large interest in the corporation, together with W. D. Townsend, of Chemulpo, Korea; S. L. Selden, of New York City; M. P. Sayce and F. B. Lawson, of London. A. H. Collbran is general manager in Korea. The company is capitalized at $500,000 or 5000 shares at $100 each. A 20-stamp mill was started last November and 20 more have been added and are now in operation. Each stamp has a duty of four tons in 24 hours. The ore averages $18 per ton in gold and copper, the copper being estimated at 12c. per pound. The ore is crushed and amalgamated, goes over plates to James tables, thence to a Richards pulsator classifier, the coarse product to a tube-mill, and all fine and slime over plates again and to James slime tables. The screens on the batteries are 20-mesh. The sulphides contain about 28% copper, in bornite and chalcopyrite; also some bismuth, galena, and pyrite. Below the mill is a canvas plant with two tables 50 ft. long and 14 wide, with a strip down the centre to facili-

Taracol Head-Frame.

Miners at Taracol Mine.

tate sweeping. One side is swept at a time with hose and flat nozzle under good water-pressure. The canvas is laid horizontally and laps slightly. The main vein at Suon is 40 ft. wide, the pay-streak averaging 8 ft. It is all developed through adits. About ten Americans and 600 Koreans are employed. The concentrate is shipped to the Pacific coast for treatment. Suon is exceptionally well situated as to shipping facilities as the mines are only eight miles from a branch of the Pyeng Yang river, and water transportation is available from there. Mr. Collbran, the general manager, estimated the ore reserves on December 31, 1909, as 172,450 tons of ore at $18.38 per ton. The company is in a healthy financial condition and will surely grow.

The Korean Exploration company at Chiksan, in South Chenn-do province, has been developing its mines, and in the past year its four Nissen stamps put through 7000 tons of ore. The net return per ton was $13.60, with concentrate still to be shipped. The ore contains one per cent concentrate worth $200 per ton. The company is now putting in three 1-stamp, Hendy, quadruple discharge batteries, and two more Standard concentrators. Three feet of the vein carries ounce ore, and the placer properties of the company are good. The stock of the company is owned half by Americans, and half by Japanese capitalists. One-fourth of the net proceeds goes to the Government. Most of the stock is held by a few men. The mine was badly managed for a time, but is now well on the way to become one of the really good gold mines of Korea. Albert Taylor is the present general manager, and W. S. Farnham is superintendent. Eight Americans and about 320 natives are employed.

At Saekju, twenty miles from Wiju, in northern Korea, the Western Engineering Co., controlled by Hoover & Bates, have a concession. W. S. Holloway is manager. This company paid 90,000 yen for the concession. It contains no large lode but many small quartz veins in gneiss, and some good placer ground. The ore contains about one ounce of gold per ton. The company leases these small veins to Korean tributers who pay one-third royalty. About 2000 Korean wooden stamps are now crushing 300 tons of ore per day, and saving about 75% of the gold. The Korean miner gets one-third, the mill one-third, and the company one-third, and all are doing well. A modern custom mill would be a good paying investment and would develop the country. The company should install one without delay. There is plenty of water for battery use but not enough for power. From late advices the company is preparing to erect a 20-stamp unit of a new mill. It is reported that they have enough ore in sight to run these stamps for ten years. Many of the veins in the gneiss are of sufficient width for good stoping. Some Japanese are cyaniding the tailing from the Korean stamp-mills, in Salei tubs, and making a profit. This property is only seven miles from the Yalu river.

Numerous smaller prospects are held by Japanese and Americans with a large extent of still unprospected country. Some individual Japanese are taking out gold from placer workings, while several Americans are developing quartz prospects. Morris & McGary, of Seoul, have some excellent prospects in several provinces, some of which bid fair to become good mines. In the next decade many fortunes will be made by the persevering and those who know the game. The Japanese welcome mining exploitation and are friendly and courteous to Americans in Korea.

THE DETERMINATION OF COPPER IN COPPER-BISMUTH ORES

By C. C. O'Loughlin

The following method for assaying ores for copper that carry from 0.5 to 3% of bismuth, is used at the Bogardus Testing Laboratories, at Seattle. It may be of interest to others since no data on methods suited to these conditions are generally available.

At first the bismuth was precipitated with ammonium carbonate, making two separations, but this was not found satisfactory, as the separation was not complete. The filtrates were run electrolytically, but deposits were found to turn into a dark sponge, and drop off, even with different current density, because of bismuth still being retained in small amounts. The iodide method with the above separation, was found to give low and erratic results. It was then thought possible to precipitate the bismuth as the sub-nitrate, plating the copper direct in the filtrate; but the separation was not found suitable. The following method was finally adopted and found to be highly satisfactory.

Treat 0.5 to 1 gram of pulp with 8 c.c. HNO_3, digest at low heat until fumes cease, add 2 c.c. H_2SO_4 and evaporate to SO_3 fumes. When cool, wash down cover and sides of beaker, first add ammonia, and then acidify with HCl, adding a very slight excess. Keep the volume as low as possible. Have a 500-c.c. beaker ready, containing about 250 c.c. hot water, and a little ammonium chloride. Pour assay into this slowly with constant stirring and allow to settle one-half hour. Filter off the insoluble and the bismuth, which has been precipitated as the oxichloride, wash well, add 2 c.c. H_2SO_4 to the filtrate, and precipitate the copper with sodium hyposulphite. Filter, wash, burn precipitate, brush into a copper beaker, and dissolve with 5 c.c. HNO_3, heat until dissolved, dilute with water, add 3 c.c. H_2SO_4, and plate $N.D._{100}$ 0.10 amperes.

If preferred, the copper can be titrated with sodium hyposulphite by taking the solution nearly to dryness. After dissolving the copper precipitate in HNO_3 neutralize with sodium carbonate, acidify with acetic acid, and titrate. Bismuth can be run in the residue from first filtration by dissolving away from the silica and precipitation as oxichloride, burning and weighing as oxide.

Copper mining in Alaska, according to Bulletin 442, of the U. S. Geological Survey, was less active in 1909, when seven properties were productive, as compared with nine properties in 1908. The output for 1909 was valued at $536,211; that for 1908 at $605,267.

Design of a Mine Plant

By J. W. Whitehurst and W. P. Cary

Part II—Hoisting

*Load and Speed.—The hoist is to have a capacity of 225 tons in 12 hours, to operate in a two-compartment shaft (see Fig. 1 and 3). The compartments are 980 ft. deep and vertical with a section of 4 ft. by 4 ft. 6 in. in the clear with the exception of 4-in. guides. The cages are to be light-weight steel, weighing, approximately, 1000 lb. The cars are to be of the type known as 'Leadville,' holding 14 to 15 cu. ft., or 2500 lb. ore, and weighing approximately 650 lb. each.

If 225 tons be hoisted through one compartment in 12 hours, there will be required 4 minutes for a round trip; if hoisted in two compartments there will be available 8 minutes per round trip for each cage. For purposes of calculation all ore is considered as hoisted from a depth of 1000 ft. It is assumed that 20 seconds are necessary for acceleration and slowing at the beginning and end of the trip. The weight would be: weight of cage, 1000 lb.; car, 650; ore, 2500; ¾-in. rope, 880; weight due to friction, 415; total, 5445 lb. This total weight is the rope-pull in unbalanced hoisting. Friction is 10% of the weight of cage, car, and ore, due to friction of rope over the sheave and of cage on the guides. The maximum speed of hoisting is to be 800 ft. per minute.

Acceleration may be estimated as follows: $S = \frac{Vt}{2} = \frac{14 \times 20}{2} = 140$ ft. for acceleration at both top and bottom of shaft. Where S = distance in feet in which to accelerate; V = final velocity of acceleration in feet per second; t = time of acceleration in seconds; $1000 - (2 \times 140) = 720$ ft. or the distance in which a speed of 800 ft. per minute is maintained. The time therefore during which a constant speed of 800 ft. per minute is maintained is 0.9 minutes; acceleration at start, 20 seconds; at end, 20; running at constant speed, 54. The total time that will be necessary to start cage from rest, raise it 1000 ft. and bring to rest again, will therefore be 94 seconds, and the total time necessary for a round trip is 3 min. 8 sec. Then, 8 min. − 3.12 min. = 4.88 min. or more than one-half of the total time for caging at both ends, lowering men, timbers, and supplies.

When hoisting unbalanced, the figures would be: force required to accelerate cages, cars, and ropes, 119 lb.; therefore 5445 + 119 = 5564 lb. maximum rope-pull during period of acceleration; $\frac{5570 \times 800}{33{,}000 \times 0.8} =$ 159 hp. maximum required as in-put to hoist motor; $\frac{5445 \times 800}{33{,}000 \times 0.8} = 155$ hp. normal requires, when running at 800 ft. per minute, as in-put to motor, 80% being assumed as mechanical efficiency of hoist.

When hoisting in balance: weight of cages, 2000 lb.; ore, 2500; rope, 880; cars, 1300; friction on sheaves and guides due to weight of cages, cars, and ore, 580 lb.; weight to be used in calculating accelerating force when hoisting in balance, 7340 lb.; $F = \frac{7340 \times 0.666}{32.2} = 151.5$ lb. Weight of ore, 2500 lb.; rope, 880; friction, 415; total, 3795 lb. 3795 + 151.5 = 3946.5 lb. maximum rope-pull during period of acceleration; $\frac{3946.5 \times 800}{33{,}000 \times 0.8} = 113.5$ hp. maximum required as in-put to hoist motor: $\frac{3795 \times 800}{33{,}000 \times 0.8} = 108.5$ hp., normal required, when running at 800 ft. per minute, as in-put to motor.

The rope pull, when up to speed, is 5445 lb., but in the calculations for acceleration the extra pull was found to be only 119 lb. for the 5000-lb. rope-pull. Evidently in practice this factor would be much greater, probably as high as 1500 lb. or more. Assuming this as 1500, the maximum power would be increased from 155 to 198 hp. for unbalanced hoisting, and from 108.5 to 150 hp. for balanced hoisting. This discrepancy is due to the fact that in calculations only the masses of the two cages, cars, ropes, and ore are considered to be accelerated; while to this amount should be added the masses of the sheaves, drums, gears, and motor armature; also there should be taken into consideration the friction of the sheaves and shafts, and internal frictions of the hoist and motor.

Perhaps as good a method as any would be to compare the kilowatt in-put curves, taken from plants where direct-current electric hoisting with Ward-Leonard control is used, and from the analogy with these curves, draw a curve accordingly for this particular installation. Fig. 4 shows this. The full line

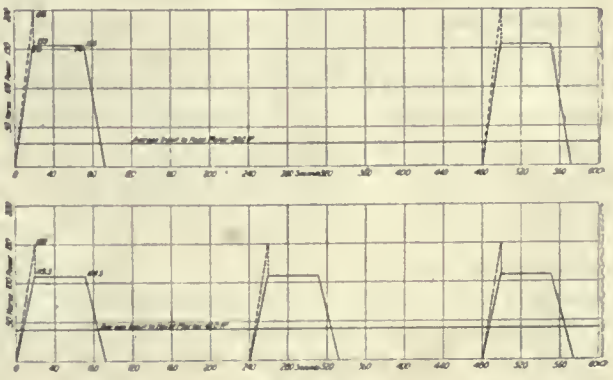


Fig. 4.

indicates the horse-power in-put to the hoist-motor according to calculations, and then, by comparison assuming the value of F to be about 1500 lb., the peak load is shown in the dotted line. This maximum peak load, however, is only momentary and has not been considered in selecting the hoist motor, for the motor could stand this large overload for the short period that it would be required.

The hoist selected is equipped with a 200-hp. motor; double drum, size No. 8; each drum is 66 in. diam. by 30 in. between flanges. For foundation plan see Fig. 3. This hoist is provided with post brakes and band clutches. Inasmuch as the hoist-motor is called upon for its maximum load (159 hp.) during only a short interval, and the time intervals

Mining and Scientific Press prize thesis, presented as part fulfilment of the requirements for graduation at the Colorado School of Mines, June 1910. Continued from p. 205.

are spaced at least 3 min. 8 sec. apart, a 200-hp. motor is unnecessary. A 125-hp. slow-speed D. C. motor (6-pole, 230 volts, 550 r.p.m.) is therefore selected. This motor is capable of carrying a 28% overload for 15 minutes and can deliver 160 hp. during the short time required.

Shaft-House and Head-Frame.—The shaft-house is to be a 32 ft. by 25 ft. 6 in. frame structure, with frame work of 8 by 8-in. timbers, covered with 1 by 12-in. boards; equipped with shingle roof sloping

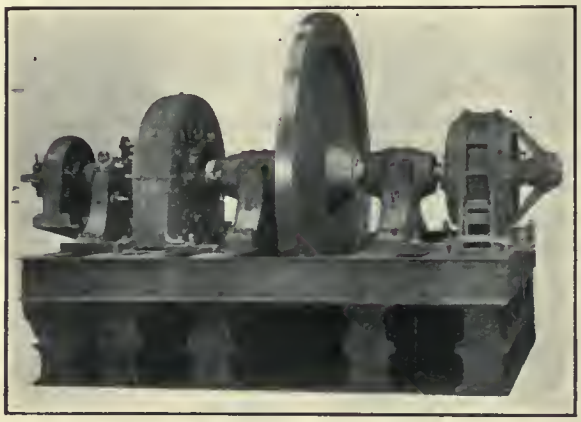

Fig. 5. Motor Generator With Flywheel.

45°. Windows are to be placed only at the ends of house. (See Fig. 1 and 3 for elevation and plan of shaft-house.) The head-frame is to be of 12 by 12-in. timbers throughout and 50 ft. from floor of shaft-house to centre of sheave, the braces to be placed at an angle of 60° with the horizontal, all timbers to be securely tied with 1-in. steel rods. The posts and braces of the head-frame are to be set in cement piers properly embedded in the ground.

Transforming.—The main current, as supplied by the power company at 6600 volts (3-phase, 60 cycles), is to be transformed to 440 volts in the transformer-house, at the surface plant, before entering the power-house. The horse-power required by the several departments, as in-put to the switchboard, is as follows:

	Hp.	Kw.
Motor-generator set	75.0	56.0
Pumping	36.8	27.0
Compressing	285.0	212.4
Lighting	17.6	13.1
Shops	12.5	9.3
Total		318.2

For transforming this three transformers have been selected, type H, 125-kw. delta connected, to be placed at one end of the transformer-house, two smaller transformers to step the 440-volt current down to 110 volts, for surface lighting and shop motors, will be placed in the same house. The other equipment of the transformer station will consist of knife switches, oil switches, and lightning arresters. This equipment is furnished and set up by the company selling power. The transformer-house is to be built of corrugated iron.

Power-House.—For dimensions of the power-house and location of the various units, see Fig. 3. On account of the heavy wind stresses and snow loads, which are often simultaneous in this locality, a heavy roof-truss has been selected. It is to be supported on 12-in. steel columns, built in the brick side-walls of the building.

Motor-Generator Set.—With electrically-operated mine plants in general, and more especially small plants, where hoisting is the major load-factor, it is desirable to have as high a station load-factor as possible. This is important economically in two ways: first, when the power is generated by an isolated plant at or near the mine, the more uniform the demand for power, the smaller may be the rated capacity of the generating station, and the greater the freedom from undesirable fluctuations of voltages in the system in general. In the second place, when power is purchased, where the charge is based on the maximum peak-loads, the saving is material with a small increase in the load-factor, which tends to equalize the demand on the mains. The latter case applies to this problem, and with this in view a motor-generator set with fly-wheel accumulator, according to the Ilgner system, with the Ward-Leonard control for the hoist-motor has been selected. (See Fig. 5.) This set consists of an A. C. rotor-wound, variable-speed induction motor, direct connected to a D. C. generator with a fly-wheel on the same shaft as the armatures of the motor and generator, and between the two. The generator supplies current for the direct-current shunt-wound hoist-motor. The fields of both the generator and the hoist-motor are excited by a small 250-volt ex-

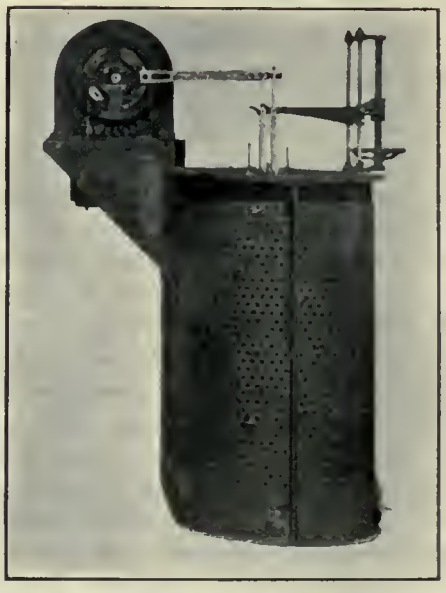

Fig. 6. Automatic Slip Regulator.

citer on the same shaft. A Terrill automatic regulator keeps the voltage constant, regardless of the variations in speed of the set.

The speed regulation of a D. C. motor has many advantages both as to economy and convenience over that of an A. C. motor. In this system the control is as follows: the controlling resistance is placed in series with the generator field, by varying this field excitation the output of the generator is varied and therefore the speed and direction of rotation of the hoist-motor is controlled. The only resistance, and consequently the only loss brought in, is that in the field excitation of the generator, and this is small

compared with that introduced in the control of an A. C. variable speed motor. This is an important advantage over ordinary A. C. hoisting systems. The A. C. motor is supplied by 3-phase, 440-volt, 60-cycle current from the main transformers. Its speed is controlled by an automatic slip regulator (Fig. 6), which cuts resistance into or out of the armature circuit as the load on the generator increases or decreases. Increasing the resistance in the armature increases the slip, and this allows the fly-wheel to give up its energy, and *vice versa*; the fly-wheel stores up energy as the load drops off, thus allowing the motor to expend part of its energy in accelerating the fly-wheel. By this means the extreme variations of the hoist-motor are transformed into practically a constant demand from the A. C. mains and the loss due to the resistance introduced, at times, in the rotor is negligible.

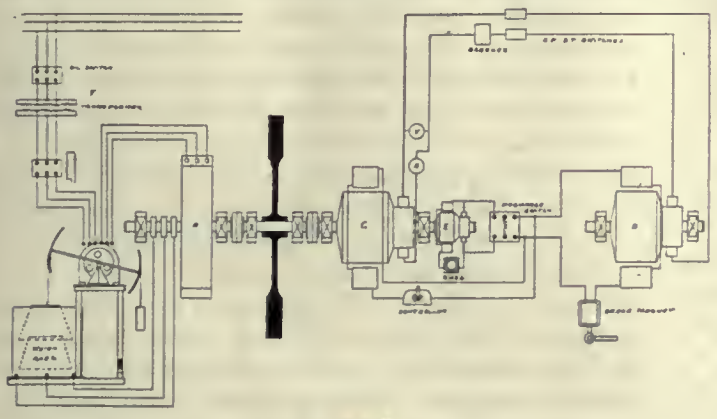

Fig. 8.

Hoist-Motor.—It is seen from the above that a slow-speed D. C., 125-hp. 'DLC' General Electric motor has been selected to run on 230 volts at 550 r.p.m. and capable of delivering 160 hp. for 15 min. This gives an overload of only 28%. This motor is shunt-wound and connected to the hoist by a double reduction in gearing. The gears are to be steel and machine cut. The drum of the hoist is 66 in. diam. and revolves at 46.2 revolutions per minute.

Direct Current Generator.—A 100-kw. 6-pole, 250-volt, 675 r.p.m. (variations 547.2 to 684 r.p.m. allowable) specially constructed direct-current generator has been selected. This generator has to be especially constructed to be able to withstand the variations in speed and still deliver full load.

Alternating Current Motor.—This motor will be required to operate under a 20% slip below full-load speed. This slip has been used because any motor similar to the following will operate under 25% slip with only a slight decrease in efficiency. With larger motors the slip cannot be so great, and for faster hoisting the slip must be less.

Fig. 4 shows a curve plotted from horse-powers and time of hoisting of both balanced and unbalanced hoisting. It is found that for balanced hoisting the average in-put to the hoist motor is 41 hp. or 30.75 kw., and for unbalanced hoisting 30 hp. or 22.5 kw. These curves are integrated for a cycle and divided by the periods, this giving the average in-put to hoist-motor. Assuming the average efficiency of generator, motor, and fly-wheel to be 55%, which is approximately that used in general practice and allows for efficiency of motor and generator and friction of shaft on bearings, the in-put to the A. C. motor must be for the worst case (balanced) at least 75 hp. A type 'M' General Electric 60-cycle, 3-phase, 440-volt, 10-pole, 720 r.p.m., 75-hp., slip-ring, alternating-current, induction motor has therefore been chosen. The full load-speed of this motor is 684 r.p.m., and with 20% slip (unbalanced) it will be 547 r.p.m. These are the limits between which the fly-wheel must give up the required amount of energy. The torque produced by the full-load value of the main-line current in the rotor is balanced, in the installation, as outlined, by the weight of the moving parts of a water rheostat, which is used in connection with the slip regulator; in case water cannot be had for such purposes a block resistance can be used.

Fly-Wheel.—The fly-wheel has to deliver the difference in power between the maximum required by the hoist-motor and that delivered by the A. C. motor to the hoist-motor. A solid cast steel fly-wheel, 10 ft. diam., and slightly hollowed between the rim and the hub has been assumed. The proportions are such that the centre of gyration is at a point approximately 0.78 of the total radius from the centre of rotation. The maximum horse-power required by the hoist-motor is 159; the minimum delivered by A. C. motor, 30; the maximum required of the fly-wheel, 129. The kinetic energy of the fly-wheel, or any rotating body, is equal to the product of the weight of the body by the square of the linear velocity of the centre of gyration divided by twice the acceleration due to gravity. Then $E = \frac{WV^2}{2g}$. When reckoning the kinetic energy between two velocities V and V_1, this formula becomes $E = \frac{W(V^2 - V_1^2)}{2g}$ where V = maximum linear velocity of the centre of gyration in feet per second, when wheel is working 684 r.p.m. V_1 = minimum linear velocity of the centre of gyration in feet per second when wheel is working 547.2 r.p.m. Radius of gyration = 0.78r = 0.78 × 5 = 3.9 ft. when r = radius of fly-wheel in feet. V = 27.9 ft. per second. V_1 = 22.7 ft. per second. The maximum velocity of the rim = 21,500 ft. per minute, therefore a cast-steel fly-wheel can be used. Total time for hoisting cage with load, 94 sec.; total time for retarding cage with load, 20 sec.; period during which fly-wheel gives up 129 hp., 74 sec. In order to furnish the necessary horse-power (129) during the required time interval the weight of the fly-wheel is calculated as follows:

$$\frac{W(V^2 - V_1^2)}{2g} = 129 \times 550 \times t$$

Where t = the time in seconds during which 129 hp. is required of the fly-wheel. Transforming and substituting $W = \frac{2 \times 32.2 \times 129 \times 550 \times 74}{(27.9)^2 - (22.7)^2} = 12{,}910$ lb. —call this 13,000 lb. Therefore, a fly-wheel weighing 13,000 lb. is selected. For balanced hoisting this weight of wheel will call for a slip of the A. C. motor of 6.29%. From the rates guaranteed by the com-

pany from which power would be purchased, hoisting without the motor generator set will cost $80.50, and with it $37.95 per horse-power year. This gives a saving per horse-power year of $42.65, and merely shows that, even with a small plant, there is a saving in cost of hoisting of 52.9%. See Fig. 8 for the diagram of wiring of motor generator set.

Conclusion.—This method of hoisting was selected because of its advantages over the common system in safety, better control, and economy of operation. As regards safety, it is generally known that in electrical hoisting there is an element of danger, due to the fact that the power is apt to be shut off at any moment. With this system there is enough energy stored up in the fly-wheel to enable the operator to at least lift the men out of danger, and in all probability would be sufficient to hoist them all to the surface. This is especially important when sinking, for the men are then in a dangerous position and must be certain of being carried out of danger. That the plan adopted affords the necessary security is indicated by the fact that at the Kendall mine, Kendall, Montana, where a similar installation is in use, two trips with the cages loaded and five trips when empty can be made with no power in-put to the A. C. motor. Similar examples might be cited in German practice. The operator can work more quickly and with greater certainty with the Ward-Leonard control than with any other, and this is a decided advantage when compared with A. C. hoisting. The system has further the advantage of electrically breaking the load in such a way that the operator has complete control over the moving parts, and a retardation of the same returns and appreciable amount of energy to the fly-wheel. There is no excessive wear on the hand breaks, for these are only used to hold the load. The hoist can also be equipped with apparatus that at the proper moment automatically reduces the speed, and prevents overwinding. The electrical units, while expensive, are not so much so but that the saving in cost of operation will pay for them in a short time. This system has here been applied to a small mine, and the calculated saving in operating costs is gratifying. In mines where large tonnages are hoisted, each load being large and the hoisting time short, the peak on starting would be exceedingly great. By using very large fly-wheels, or even two of them, as is often done, the cost of operation would be reduced proportionally much below that of a small installation like this. This system is particularly applicable to a concern that is operating several mines in a district and generates its own power. The generating station can be situated, in such a place, near a railroad, where coal and water may be secured cheaply, or in a locality where water-power may be utilized. In such case a motor-generator set with fly-wheel is installed at each shaft and the size of the main generating station would be proportionally greatly reduced.

Rate of flow through the large 42-frame slime-press at the Homestake cyanide plant, at Deadwood, South Dakota, is close to 520 tons in 24 hours, and the press is idle part of the time.

THE SKIDOO MINES COMPANY

The Skidoo Mines Co., operating a group of 23 claims in the Panamint range, Inyo county, California, has recently entered the list of dividend-paying gold mines. The property lies on the southwestern slope of Tucki mountain at an elevation of about 5500 ft. above sea-level. The country hereabouts consists of a series of rolling hills and gentle slopes, separated from Death valley by a range of Paleozoic limestone hills. These hills are scored by deep canyons.

Granite of post-Jurassic age comprises the principal country rock in the vicinity of the property. Cutting this granite are dikes of syenite-porphyry and smaller intrusive bodies of diorite, quartz-monzonite and porphyry. The auriferous veins are found in fissures in the granite and in shear zones between the granite and syenite-porphyry. The gold occurs free in a quartzose gangue accompanied by limonite, hematite, and some galena. At 300 ft. the ore is oxidized and it is expected that this condition will obtain until a much greater depth is reached.

Work is being done on four veins through two tunnels and two shafts. The maximum depth attained is 300 ft. The average width of the orebodies is 4 ft., the ore running from $12 to $20 per ton, average about $15 per ton. Ore is treated by amalgamation, concentration, and cyanidation, in a 50-ton mill. About 65% of the gold is recovered on the plates. The concentrate, which averages about $300 per ton, is shipped to the Midvale, Utah, plant of the United States S. R. & M. Co. Tailing is cyanided. The total recovery amounts to 90% of the gold in the ore.

Power for the mine and mill is supplied chiefly by water which is brought from Telescope peak, 23 miles distant; 8 and 10-in. pipe being used. The power plant includes also several gasoline engines, used as a reserve in case of trouble with the pipe line. At present there are 40 men employed in and about the mine and mill. Following is a statement of the operations of the company from June, 1909, to June, 1910, inclusive (13 months): tons milled, 14,726; bullion receipts, $189,089; total expenses, $87,661; development, $8819; profits, $92,617; time lost in mill, 88 days. On August 3, the company shipped to the mint 552 troy ounces of bullion which netted $7595. This was the result of a clean-up of batteries and plates after a run of 13 days. Time lost during the 13 days run was 15 hours.

For the past six months the average cost of mining has been $4.13 per ton; this includes administration and miscellaneous charges. The cost of milling, including administration and cost of power plant upkeep, has been $2.75 per ton. Thus the total cost of mining and milling, including all work about the mine and mill, except development work, has been $6.88 per ton. The second dividend of the company was paid in July, 1910, and amounted to 5c. per share on a capitalization of 1,000,000 shares, or $50,000. The principal stockholder in the company is E. A. Montgomery, of Los Angeles.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Conical Tube-Mill Grinding

The Editor:

Sir—The comparatively recent use of the conical mill for fine grinding has brought up many questions, especially among actual users of the apparatus, concerning its ultimate limit of efficiency. It seems that this type of mill, while possessing certain attractive features of design which should add to its efficiency, has only been tried out grinding a few classes of ore under somewhat similar conditions. While the manufacturers of the different makes of conical mill are confident that it forms a step forward in the art of fine grinding, they are admittedly doubtful as to its limitations. Further and more detailed data are desirable on this subject, and with this in mind I submit the following figures.

It must be understood that the performance of both mills, as shown by the figures, is based on similar operating conditions, both being run on a hard quartz gold ore. The work shown was done at Polaris, Yuma county, Arizona, and the performance of the different grinding devices was carefully watched by the general manager of the company, while certain adjustments were made by him with a view to securing the best possible results from the machines in use.

The conical mill was run at a speed varying from 18 to 30 r.p.m. and experience showed that 24 to 25 r.p.m. gave the best results. An increased speed above this had no beneficial effect, while it probably increased the wear on linings and pebbles and, of course, needed more power. At a speed of 25 r.p.m. about 25 hp. was required. The mill was charged with 3½ tons of pebbles. The Abbé tube-mill was charged with 8 tons of pebbles, which filled it about 6 in. more than half full. Performing the work indicated in the above test 30 hp. was required.

These figures are submitted with the idea that they will prove of interest to millmen in general. It would be helpful to many engineers who are encountering similar problems if other members of the profession would publish accurate data relating to their own experiences.

STUART TOD.

New York, July 29.

Crushing by Stages

The Editor:

Sir—It is with some reluctance that I enter into a controversy with so experienced a writer as Algernon Del Mar, especially on a question that cannot be anything but a hypothetical one at best. The so-called 'efficiency' of grinding machines, as of so many other industrial contrivances, is very uncertain, dependent as it is on many elusive factors that nobody can control. If this be true in regard to so widely divergent types as jaw-breakers and gyrating crushers, stamp-mills, and Chilean mills, and of the large number of varieties within the latter class, where the preference for a certain machine develops simply into a question of local conditions, and often personal inclinations and prejudices, how much more difficult, if not impossible, must it be to decide as to the superiority between so closely allied methods as the ones under consideration, namely, grinding in two cylindrical tube-mills, with an intermediate sizing of the product as preferred by Mr. Del Mar, as against grinding in a conical mill alone. The latter, in my estimation, has not been given the proper opportunity to prove its merits (or weaknesses), and Mr. Del Mar himself takes his stand against it on entirely hypothetical grounds. At least he produces no concrete evidence for his preference, and I doubt whether the results upon which he bases his opinion have been recorded with that degree of accuracy necessary to preclude any possible error of judgment.

To do so would be impossible, except with the most scrupulous attention to details, as was demonstrated by the recent drilling contest on the Rand, where the most elaborate precautions had been taken to prevent any bias and the results were recorded with the utmost care. Nevertheless, the decision, in favor of a certain drill, was so unsatisfactory as to call for a second competition, and with so disappointing a result that even the S. A. Chamber of Mines, under whose auspices, together with the Transvaal Government, the trials were held, considers them of little importance, while the Johannesburg correspondent of *The Mining Magazine* pronounces them void of all finality and capable of yielding entirely different results if the contest were to be conducted again under the identical conditions. If this is the result of one of the most scientifically organized tests of modern times—as far as efficiency of mining machinery under actual working conditions is concerned—and if this agrees with the experience we gain every day when we attempt to condemn a machine or method on the strength of an apparent failure under certain conditions, I wonder at the courage of Mr. Del Mar in assuming the rôle of supreme judge when he declares that "the fra-

ternity may have found the weak points of the conical mill and prefers two cylindrical tubes, sizing between, or crushing in two stages instead of in one machine."

That I perfectly agree with him in regard to the value of crushing in stages is made clear in my first remarks (the ones that gave so much offence), and for that reason I consider the principle of the conical mill correct, inasmuch as it is certainly better to perform the work in one machine, when possible, instead of in three. If in actual operation the results should not correspond to the principle involved, after exhausting all possible means to reconcile both, then the machine will be abandoned altogether, or relegated to its proper sphere. That this stage has not been reached yet, I am free to say, and all the more so as there are authorities who favor the conical mill and large enterprises that are perfectly satisfied with its operation. Personally, I have no evidence to offer, either way; and, if I had, I would not consider it conclusive. The fact is that I have never given this matter much attention and was therefore surprised to see Mr. Del Mar make my inconsequential remarks the subject of attack. I still maintain that the principle upon which the conical mill is built has not been sufficiently recognized by the mining fraternity, as is shown by the small number of installations that have been made. Mr. Del Mar tries to prove the inability of the conical mill to accomplish the desired result by doubting that much selective action takes place on the part of the pebbles, and claims that he has learned this from his experience. It would be interesting to know wherein this experience consists, because to me it would seem more plausible to expect considerable selective action owing to the spherical form of the pebbles, which should give the fine particles in the pulp an opportunity to escape the impact between the fewer large pebbles near the inlet (but catching the larger particles) and submitting them to the crushing action of the more closely packed small pebbles near the discharge end. Mr. Del Mar himself admits a 'pronounced' sizing action in the case of dry ore. If so, what right have we to assume *a priori* that all, or nearly all, such action ceases once water is introduced? That the greater fluidity of the water must have some effect will probably be admitted, but in what direction, and to what extent, remains entirely a matter of speculation.

Mr. Del Mar's comparison of the conical-mill principle with that in a battery of stamps of different weights appear to me quite irrelevant. An analogy might be claimed if the ore entered the battery at the end of the heaviest stamp and left at the opposite end, but even then the points of similarity are so few, and those of difference so many, that their comparison seems hazardous. From Mr. Del Mar's uncompromising attitude toward the conical mill one would feel inclined to suspect that his trial with the same must have been disastrous (possibly due to the mill—possibly not). Let it be hoped that such is not the case, and that his rush to the defence of the 'fraternity,' as well as his somewhat peremptory challenge to me, are not the reaction of a pardonable state of mind under such conditions, but his unmixed desire to dispel, in an entirely disinterested manner, any favorable impression in behalf of the conical mill my remarks may have created, because contrary to the truth, as he sees it.

Before closing I should like to state that the omission of the word 'except' somewhat obscured the meaning in my last communication. The last sentence of the last paragraph but one should read as follows:

"If we, then, choose our stamps so that their weight does not exceed that required to accomplish the breaking of the ore, we should have as economical a crushing machine as we can expect, except for the smallest sizes, where stamps would become impracticable, and tube-mills, preferably the conical variety, would take their place."

FELIX CREMER.

Needles, California, August 7.

The Editor:

Sir—There are one or two items that might be added to the discussion on stage-crushing, which has recently appeared in the columns of the *Mining and Scientific Press*. Without taking exception to anything that has been said previously we may safely say that the question is a matter of cost and that efficiency is only of value to the extent that it affects cost. The plant that everyone is striving for is the one in which the treatment cost (including amortization charges) plus value in the tailing shall be the minimum. Bearing this point in mind, the size of the mill and the amount of ore on hand will usually have a greater influence on the selection of equipment than the differences in efficiency that stage-crushing may produce. The largest plants, which must in any case have a large installation of machinery, can look more closely at the advantages of stage-crushing than others. Again, the mechanical problem of transferring the pulp through a long series of machines is a serious one. Either several feet of that never too plentiful mill height must be sacrificed or some sort of elevator must be put in. In the case of stamps, a departure from the usual arrangement, in a single row would be objectionable. An example of how stage-crushing may be carried too far is furnished by a mill equipped with a large crusher discharging to a trommel whose oversize goes to a short head crusher. No grizzly was used ahead of the first crusher. Had a grizzly been used and the first crusher set up one inch, an elevator, trommel, and crusher could have been eliminated and the size of the building materially reduced. The capacity would still have been ample so that one shift could supply the mill for a day. It is hard to see how stage-crushing pays in such a case.

The 'removal of the fines as soon as made,' so frequently urged upon metallurgists, is no child's play, and although theoretically correct, it must not be done until it can be done at a profit. It would seem that each case is a separate problem whose answer reads in dollars rather than in percentages.

L. B. EAMES.

Pueblo, Colorado, August 9.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Discovery of cinnabar in the placer mines on Batwaan creek, Benguet, Philippine Islands, is announced by W. D. Smith, chief of the Division of Mines.

Pure aluminium resists corrosion to a remarkable degree, but the presence of silicon in the metal greatly impairs this property of the metal. The greater part of the aluminium manufactured today is 99½% pure.

Tailing is used to fill abandoned workings of some of the mines on the Rand, and in several of them the tailing is run into the stopes through diamond-drill holes bored from the surface. This method prevents the rapid cutting of iron pipes by the sand, which has given trouble in some instances.

Precipitating gold from cyanide solutions by means of cuprous chloride after acidulating the cyanide solution with sulphuric acid is not a new process, but was introduced by P. De Wilde, of the University of Brussels, nearly fifteen years ago. It is known as the De Wilde process.

Stamp capacity is attracting much attention on the Rand. It is estimated that under ordinary conditions (there) a 2000-lb. stamp will crush 20 tons of ore through a 4-mesh screen, the pulp containing about 75% of + 90-mesh product. A standard 22-ft. tube-mill makes an output of 250 tons per day, grinding to a pulp containing not more than 10% of + 60-mesh material.

A secondary vein of quartz sometimes occurs within the large mass of a quartz vein, differing from it in physical appearance, and usually also in value. An instance of this character may be cited in the case of the Clover Leaf (Uncle Sam) mine, on Elk creek in the Black Hills of South Dakota, where an irregular small vein of white quartz occurred, in the midst of a large mass of bluish white iron-stained quartz. The best ore in the mine came from the small white vein, which contained groups of crystals of galena with coarse gold.

A 'packing-block' employed in head-frame construction is a block placed between the minor tie braces of a frame of laminated construction—built up of boards or planks spiked together. The tie braces are either spiked to the sides or are 'let into' the posts and back-braces, and the packing-block is spiked midway of these, and between the two planks forming a tie-brace, its function being to reduce vibration and to stiffen the structure. One or more packing-blocks may be inserted in each tie-brace, depending on the length of the brace.

Quartzite is a quartz sandstone that has been firmly cemented by the infiltration of secondary silica. Generally the silica forms an envelope around the original quartz grains of the sandstone, enlarging them. This can best be seen in a thin section under the polarizing microscope, when each original grain may usually be distinctly seen in outline within the envelope of new infiltrated and crystalized silica. Quartzite is sometimes so completely silicified that in the hand specimen its origin might pass unnoticed, unless a slide were cut for microscopic determination. Usually, however, in the field quartzite may be identified readily by its appearance in place. Aplite, a fine-grained micaless granite, is sometimes so completely altered by infiltration of silica, that it has frequently been mistaken for quartzite.

Concrete is most useful about the mine, either underground or on the surface. Foundations, retaining walls, bulkheads, shaft and tunnel linings, floors, side-walls, battery-blocks, and other structural features can be made of concrete. Reinforcing it with bars of iron or steel, or sections of old hoisting rope greatly strengthen the concrete. Excellent tanks for holding water or fuel oil can be built of concrete, either in a pit beneath the surface or merely resting upon it. Not long since the city of New Ulm, Minnesota, had constructed for the municipality a reinforced concrete tank, or reservoir, with a capacity of 1,000,000 gal. It is cylindrical in form, 75 ft. diam., and 30 ft. high, with a conical concrete roof. The concrete was made of screened gravel of sizes from ¼ to 2½ in., with a mixture of coarse and fine sand, and cement in the proportions 4-2-1, respectively. The reservoir is above ground and is water tight.

Ventilation while driving an adit is often poor until a raise can be made to the surface from some point well in the adit. When the drift advances beyond the raise the circulation of air will probably become poor again, but will be aided somewhat by the air currents between the mouth of the adit and the raise. Circulation may be much improved by carrying a 10-in. pipe, either of wood or iron, well toward the face of the working, the outer end extending upward, like a chimney. The air current will flow into the tunnel and out through the pipe. A raise will not then be necessary. If there is much wind, this may be utilized by placing a triangular sail above the pipe, the cloth converging to the mouth of the pipe like a funnel. This sail must be adjustable so that it can always be set facing the direction of the wind, which will drive down the pipe to the face and out of the tunnel, the natural direction of the current being reversed. Still another method may be employed by building at the mouth of the adit a furnace of rocks plastered with mud. The furnace is provided with a stack, and the pipe from the adit is entered beneath the grate to supply the draft. Beneath this pipe construct a door, for natural draft which can be closed. When the fire is well under way, close the door, and the air-supply to keep up combustion will then be drawn from the adit through the pipe, pure air from the outside flowing in, to supply its place, thus establishing a continuous circulation. When the furnace and pipe are of liberal size this method of ventilating either adit or shaft, is very effective.

LONDON

Electricity on the Rand.—Foldal Copper & Sulphur.

The great progress of electrification of machinery on the Rand has drawn attention once more to the history and present position of the Victoria Falls & Transvaal Power Co., which has done so much to bring about this desirable economy. The company was formed in 1906 under the auspices of the British South Africa Co. to establish power-supply stations in the Transvaal and Rhodesia. The primary object was to utilize the Victoria Falls on the Zambesi river, and secondarily to establish steam-power installations on the Rand. For various reasons the first part of the program has been postponed and operations were centered on the latter. The steam-plant of the General Electric Power Co. at Driehoek was acquired and also that of the Rand Central Electric Works at Brakpan in the East Rand. Subsequently another plant was erected at Simmer Pan, and plans have been completed for a third at Rosherville. The Brakpan plant was put into commission in the early part of 1909 and the first part of the Simmer Pan plant the following July. The Simmer Pan plant has been extended and the capacity is now 27,400 hp.; also the Brakpan plant has been increased by 9700 hp. The Rosherville plant will consist of five steam-turbine sets of 9600 kw. each and four air-compressors of 4000 hp., each driven by steam-turbines; part of this will be ready at the end of 1910 and the rest at midsummer 1911. The business of the company is extending so substantially that another installation is under consideration. For this purpose an agreement has been made with the Vereeniging Estates and Lewis & Marks for the erection of a 53,600-hp. installation on the Vaal river, the contract calling for the purchase of coal from the companies named. The prosperity of the company has also made it impossible to discard the old Driehoek plant which is neither up-to-date nor economical. The total capacity of the plant will eventually be 155,100 hp. for electric current, and 16,000 hp. for air-compression. The amount of current supplied will be 500 million units per annum. The distribution lines will extend from the West Rand Consolidated to the Cloverfield in the far east, a distance of 45 miles. The directors speak in flattering terms of the prompt delivery of plant by the Allgemeine Elektricitats Gesellschaft of Berlin, which company secured the contract. It is notable also that much of the capital has been supplied in Germany, the issue of £900,000 debentures a few months ago having been taken by the Deutsche and Dresdner Banks. The capital has been continually increased as required for the building of the plant, and now stands at £1,000,000 in ordinary shares, £1,838,000 in 6% cumulative preference, and £1,700,000 5% debentures.

No profit and loss account has been submitted, seeing that the company is at present occupied chiefly in construction, and the profits of existing plant are carried to the balance sheet. The first installment of preference dividend will probably be paid in May next. The saving both in capital outlay and in cost of power to the companies using their current is remarkable. At City Deep, for instance, the saving in initial outlay was £124,000, and generally the saving in power bills is from 6d. to 1s. per ton crushed. Recently Bernard Price, an engineer of experience in the application of electric power to collieries in the North of England, has been appointed engineer in chief to the company in South Africa.

The Foldal Copper & Sulphur Co. was formed in 1906 to acquire an old mine at Foldal, Norway, containing cupriferous pyrite valuable chiefly for its sulphur content. The property was examined by F. Robellaz, Stanley E. Clay, and W. H. Lund. The first-named is now manager, and W. A. Carlyle is consulting engineer. The first thing to be done by the company was to put the old workings in order. Insufficient support had been provided and at the same time much of the ore had been left behind on either or both walls. In order to make the workings secure the old stopes from No. 2 level to the surface have been filled by flushing in sand and fine rock. About 120,000 cubic metres of this material has been used. The main workings consist of three adits 3500, 3400, and 1500 ft. long respectively, together with winzes, raises, and cross-cuts. Three inclined shafts have been sunk from No. 2 level at distances of 200, 1685, and 2855 ft. from the entrance. No. 3 level is to be driven at the depth of 200 ft. vertical or 250 ft. on the incline, below No. 2 level, and the work of driving from the bottom of each inclined shaft has already been begun. The shafts are in ore all the way down and if the drifts continue in ore, it will be safe to estimate the reserve between the two levels at 300,000 tons. By the end of the current financial year it is hoped that the reserve will be sufficient to provide a regular supply of 110,000 tons per year. During the year ended February 28, 97,503 tons was mined, and after dressing part of the ore, 67,453 tons was shipped. The average content was 46.6% sulphur and 1.813% copper. The profit on the sales was £13,356. From this has to be deducted London expenses £2440, and interest on loans, debentures, etc., £7480, leaving a balance of £3447, which has been used for reducing the formation expense account. The company is weighted with capital, there being £110,000 in preference shares and £200,000 in ordinary shares, £22,700 debentures, and a loan of £49,212. No dividend has yet been paid on the preference shares; as the dividend is cumulative at 6% the arrears are mounting. The prospects for the future depend on the luck of finding wide lenses of ore. At present the veins are from 1 to 3 ft. wide, but there is always a chance of finding much wider parts, for such formations are common in Norwegian pyrite deposits. The resources may also be increased by finding parallel veins of importance; cross-cutting has already revealed the existence of such veins and further research is to be undertaken by means of the diamond-drill.

MURRAY, IDAHO

New Transportation Brings Prosperity.—Monarch.—Paragon. — Jack Waite. — El Dorado. — New England Exploration Co Tests Placers.—Forest Fires.

The two forks of the Coeur d'Alene river divide the mining district of the Coeur d'Alene into two sections—the South and North. Wardner, Kellogg, Wallace, Burke, and Mullan are ranged along the South fork and its tributaries, while the Murray region is on Pritchard creek, which flows into the North fork. The towns, mines, and mills of the South fork have had railroad facilities for more than twenty years, the Northern Pacific from the east, and the O. R. & N. from the west meeting at Wallace. Both systems operate branch lines from Wallace to Burke, serving such mines as the Federal group, Hecla, and Hercules in the Canyon Creek section. The Northern Pacific, which passes through Mullan, provides spurs and sidings for the Morning, Gold Hunter, Snowstorm, and other mines. In the vicinity of Kellogg and Wardner the O. R. & N. affords shipping facilities to the Bunker Hill & Sullivan, Last Chance, Stewart, Caledonia, and others. The North fork country was provided with a railroad less than two years ago, when the Idaho Northern Railroad Co. finished the building of a line from Enaville, a distance of 22 miles up the North fork, thence 11 miles up Pritchard creek to the mouth of Paragon gulch, passing through Eagle, Murray, and the camp of the Monarch mine. While this branch is a part of the Harriman system, it is operated as a separate line, and its construction was largely due to the efforts of E. P. Spalding, vice-president and general manager for the company, who sought to hasten the development of the Murray and Pritchard creek mines. The first comers to the Coeur d'Alene country were placer miners who worked on Pritchard and its tributary streams. This kind of work was soon supplemented by the opening of quartz veins of free-milling gold ore in the vicinity of Murray, and a number of such properties were equipped with stamp-mills and operated at a profit. Among them was the Golden Chest, now closed, but rated as a meritorious mine. In the deeper

workings the ore became baser, and with this change came difficulties in milling. Within the last eight or ten years much attention has been given to the development of lead properties in that section, both in quartzite and slate formations, and the establishment of railroad transportation has given operations a healthful impetus. The side-canyons which drain into Pritchard creek expose the formations and the mineral croppings. Among these are Eagle, Butte, Bear, Paragon, and Barton gulches, on and contiguous to which are the bases of most of the mining operations.

The Monarch mine, situated on the mountain ridge between Barton gulch and Pritchard creek, has been developed by about 12,000 ft. of work, consisting of cross-cuts, and winzes and drifts on the principal vein, which is in quartzite. The major part of this work was done by the Monarch Mining Co., which within the last three years sold its majority interests to the Coeur d'Alene North Fork Mining & Smelting Co., for which E. P. Spalding is president and manager. The company's holdings consist of 30 claims between Pritchard and Barton creeks, and 15 claims on the north side of Pritchard, the development being wholly on the former group. It is stated that over $400,000 has been expended on the property in development and equipment. The discovery shaft, and No. 1 and 2 cross-cuts are on the Barton gulch slope. No. 2 cuts the vein 400 ft. from the portal, and on that level is 450 ft. of driving on the vein and a 250-ft. winze. A blind level 500 ft. long was also driven on the vein from the bottom of the winze, this being designated as the 600-ft. level. No. 3 cross-cut starts on the Pritchard creek side, about 80 ft. higher than the bed of the stream, and was driven 3266 ft. southerly through quartzite, cutting the Monarch vein 1400 ft. below the collar of the discovery shaft. To cut the oreshoot on this vein a diagonal was driven from the main cross-cut which opened the vein several hundred feet east. At this point an 875-ft. raise was made on the ore and a connection was thereby made with the 600-ft. level mentioned above. Levels were also driven from the 900 and 1000-ft. stations of this raise, and these are said to be in ore. Starting near the base of the 875-ft. raise a drift was run east 300 ft. in ore; and at the face of this drift another raise is to be made 200 ft. on the orebody to establish there an intermediate level. No. 3 cross-cut is used for ore haulage and drainage. The ore is dumped into bins at the mouth of the cross-cut, and from the bins it is passed by gravity to the company's concentrating mill, which is operated by water-power and is concentrating 60 to 75 tons of ore per day. The mill equipment consists of a crusher, two sets of rolls, trommels, jigs, tables, and vanners. The intention is to install additional equipment this season, so as to bring the mill capacity up to 200 tons per day; the new machinery is to include a Huntington mill for re-grinding the middling from the fine jigs. The mill machinery is driven by a 5-ft. Pelton wheel, under pressure of 950-ft. head of water delivered from a 2100-ft. pipe-line and a one-mile flume. The air-compressor and a No. 5 Buffalo suction fan are operated by a second Pelton wheel under 135-ft. head of water. The fan is constantly used for keeping the workings ventilated. Since January 1, 1910, eight cars of concentrate have been shipped to smelters; this sampled 60% lead and 12 oz. silver. The ore carries some zinc. The company has a force of 30 to 40 men employed.

The Paragon Con. Mining Co., which has absorbed the holdings of the Paragon and Chicago-London interests, has 42 claims on Paragon gulch, and is developing at two points. At one of these is a 300-ft. shaft and considerable other work in the way of cross-cuts, raises, and driving on the vein. At the other place is a 600-ft. cross-cut to the vein and 600 ft. of driving thereon. A raise has been started from this level to connect with another level 250 ft. higher. The country rock here is quartzite, the ore consisting of galena in a quartz and quartzite gangue, accompanied by some silver and zinc. The company has a 15-drill air-compressor, operated by water-power, the water coming from a 3200-ft. flume through a 24-in. penstock, driving the 10-ft. Pelton wheel with 205-ft. head. The shaft-house and headframe and all other equipment at the shaft were demolished last winter by a snowslide; and this equipment is being replaced. An auxiliary steam-plant is to be installed to operate the air-compressor. L. W. Stedman, manager for the company, has been in charge here for ten years and was the original locator of many of the claims. The company is made up of St. Paul, Minnesota, people, who have shown great persistence. The railroad terminal is within 1000 ft. of the Paragon camp. The Black Horse mine, controlled by P. Burke and others, is also situated on Paragon gulch, and the development and tonnage of ore exposed were sufficient to make the owners feel warranted in erecting a concentrating mill, the machinery for which has been delivered at the railway terminal. The construction work is in progress. An aerial tramway, half a mile long, is to be built from the mill to the mine.

The Bear Top mine and concentrating plant are situated on Bear gulch, 3½ miles from where the latter opens into Pritchard creek. The mine is high above the bed of the gulch, having one principal east-west vein in quartzite and slate. It is opened by a series of cross-cut levels, the vertical distance between the highest and lowest levels being 600 ft. The vein has a dip of 70°, and has a width of 15 to 18 ft. Ore of the highest grade—60 to 70% lead—is hauled to the railroad and shipped; the mill ore is said to carry 15 to 18% lead. The silver usually amounts to

Headquarters Paragon Mine.

half an ounce to each per cent of lead. There is also a considerable amount of zinc. The lowest cross-cut connects with the upper terminal of an aerial tramway, over which the ore is transported to the concentrating mill, which is operated by water-power. In the mill are 1 jaw-crusher, 3 sets of rolls, revolving screens, an elevator, 2 sets of jigs, 4 Wilfley tables. The Bear Top has been in operation several years, and George Keibler, the manager, has been in charge during the last two or three years. The Orofino is situated in Bear gulch adjoining the Bear Top, but it is not active at this time.

The Jack Waite group is noted in this section for the high-grade 'steel galena' ore which it produces. The property is under bond to the Jack Waite M. Co., which is controlled by Patrick Burke and associates. Its location is 12 miles from Murray, at the head of Tributary gulch, the latter draining into Eagle creek. The principal vein is 6 to 8 ft. wide, between quartzite and slate, and the ore comprises some lead carbonate as well as steel galena. Work is in progress and the intention is to haul the high-grade ore to the railroad.

The El Dorado, situated up Butte creek, but close to the summit, has been developed by John Murphy, M. Malley, and Charles Sullivan, who have gold-bearing quartz. The Grant & Allie, on Granite creek, is being developed by John Steen and others, who have sunk a 200-ft. shaft, opening a vein between syenite and quartzite; they are operating a small concentrating mill on lead and gold ore. The Golden Winnie, close to Murray, has just started a small mill on the property for concentrating an ore that carries gold and tungsten. The Idaho Northern group, situated on Butte gulch, has one vein that is on the contact of slate and quartzite, and another vein that cuts the contact at right angles. This belongs to E. W. Barton and Otto Nordquist, of

Murray, who are said to have found galena ore, with streaks of copper. They are building a 2400-ft. flume for the purpose of developing water-power for an air-compressor.

The New England Exploration Co., represented by Bulkley Wells and R. E. Cranston, is testing the placer grounds of Pritchard creek from its mouth a distance of ten miles up stream. The property belongs to the Coeur d'Alene Mining Co. of Boston. The latter company did considerable work at one time, sluicing some of the placer material by the aid of an Evans hydraulic elevator. The depth of the gravel to the slate and quartzite bedrock is said to be about 30 ft., and it forms a strip 200 to 250 ft. wide.

What is believed to be an important body of cinnabar has been located on the upper course of the North fork of the Coeur d'Alene river, and the locations are said to be now in control of an Eastern company. Destructive forest fires have been burning in the North fork and Pritchard creek sections for a week, and vast areas of timber have been destroyed. At one time every available man employed on the mines was engaged fighting the flames. During two days the Bear Top, Monarch, and Paragon mine and mill buildings were closely menaced by the approaching fires, but the progress of the flames has been checked and most of the property made reasonably safe. There has been virtually no rain in this part of the Northwest for two or three months and the drought is severe.

LOS ANGELES, CALIFORNIA

American Mining Congress.—American Oilfields Gusher. — Lone Pine.—Clara Consolidated.—Haynes Copper Company.

Believing that some policy of conservation with respect to oil lands will be put into effect, a number of prominent oil men of this city held a preliminary meeting last week to discuss the situation and formulate plans to present the matter, probably in the form of a concrete resolution, at the annual meeting of the American Mining Congress. The idea is to forestall any action unfavorable to the industry by suggesting something that will, while fulfilling the demands of conservation, permit unhindered development. The result of the meeting was a decision to issue a call for a public meeting, to be held at Los Angeles on a date to be selected by the chairman, S. C. Graham. The following telegram from Gifford Pinchot has been received by Sidney Norman, chairman of the convention committee of the Mining Congress: "Will reach Bakersfield September 11 or 12 for trip through oilfields. Mail me immediately literature describing situation very fully and keep me constantly advised. Regret exceedingly Mr. Roosevelt cannot come but absolutely impossible. Good luck."

The following official statement of the action of well No. 79, of the American Oilfields, which has been reported from various sources as flowing as high as 25,000 bbl., or more, during the past fortnight, will be of interest. Well brought in during May, 1910, at 1000 bbl. per day, increasing to 3000 bbl. July 25. From July 26 to August 4, excepting one day when well sanded, flow ranged from 8000 to 10,000 bbl. August 5 flowed at the rate of 20,000 bbl. in the morning, averaging 15,000 bbl. for the day. August 6, 7, and 8, average flow 16,000 bbl., reaching a maximum of 20,000 bbl. on the morning of August 8. The total yield from July 26 to that date was 143,200 bbl. Advices from the well on August 13, were that there was trouble with the well sanding.

A mill is planned for the Lone Pine zinc mine at Good Springs, seven miles from Jean, Nevada, on the Salt Lake railroad; also a railway from the main line to the mine. The mill will be built at some point on the railroad, probably near Jean. W. D. Longyear, of this city, is heavily interested. Work is being rushed on the Mudersbaugh property, south of Bouse, Arizona, recently purchased by George Mitchell of this city. Already a large force of men is at work installing two hoisting plants and an air-compressor. From 15 to 20 tons of copper ore are being hauled to Bouse daily and from there shipped to Swansea. At the Clara Consolidated, Swansea, a 175-hp. hoisting plant is being installed at shaft No. 5. This shaft is now bottomed at 180 ft., and is going down at the rate of 5 ft. per day. Work is being pushed on the new pumping plant. When the water-supply is made permanent, which will probably be accomplished within the next four weeks, there will be nothing to hinder the continuous operation of the smelter.

Ore carrying copper, lead, gold, and silver, has been found at 200 ft. in a cross-cut tunnel on a prospect at Mineral Park, Mohave county, Arizona, operated by Carlton H. Hand and E. E. Peck of this city. The vein has been penetrated 5 ft. and the hanging wall has not been reached. If developments are favorable this property will probably be turned over to the International Mines Development Co., recently organized by Mr. Hand and associates. Word has been received of the discovery of rich copper sulphide ore at the property of the Haynes Copper Co., operating at Jerome, Arizona. The ore was found at 413 ft. in the east cross-cut on the 700-ft. level. Thirty feet have been driven in the orebody, 3 to 4 ft. wide.

VANCOUVER, B. C.

Portland Canal District.—Character of Orebodies.

The Portland Canal district is attracting much attention here. A recent visitor reports that as far as could be judged by the showings made on the different properties

inspected, this district is one of excellent promise. To a mining geologist, the formation to be found in the vicinity of Bear river, and its tributary creeks, looks favorable. Generally speaking, the country rock is a schistose argillite, intersected in various directions by dikes and intrusions of igneous rocks, some of which are decidedly porphyritic. The orebodies vary in structure and composition. From the limited amount of work done it is difficult to de-

termine closely to what class of ore deposit the showings belong. In the Portland Canal mines, including the O. K., Little Wonder, and Stewart properties, the veins appear to be interbedded with the formation or to cut it at a low angle. The chief minerals are iron pyrite, galena, zinc-blende, and occasionally native silver. The gangue is chiefly quartz, sometimes with a considerable amount of calcite. Silver is the chief metal of value. On the middle fork of Glacier creek there are similar occurrences, but another class of vein is also present. There are vertical fissures, containing considerable barite in the gangue, and cutting the formation almost at right angles. The chief constituent minerals are galena, gray copper, iron pyrite, and stibnite. The value of the deposit of this character lies practically altogether in silver. The veinlets and shoots of gray copper assay in places over 2000 oz. per ton. Veins carrying compact galena are found at several points in the district. These are generally high in silver, but those at the head of Salmon river, carry gold as well. Gold is found in various places in quartz veins, and is generally associated with iron pyrite. Another class of ore deposit is that found on the Red Cliff, near the mouth of American creek. It consists of large mineralized zones of chalcopyrite and iron pyrite. Here the silver content is low and the gold high. Further up American creek bornite, zinc-blende, and chalcopyrite occur associated with barite. Silver sulphide is probably present as well, as the silver content is high. Such ore is found on the Rangoon-Bandolier group. The outlook on the whole for prosperous mining is good.

NEW YORK

Curtailment Results. — Miami Copper Co. — Greene Cananea.— Tanganyika Concessions.—Cobalt Stocks.

There is a saying of an ancient law-giver that a powerful man is never feared so much on account of what he does as on account of what he may do. The weight of the copper surplus has been a millstone, an old man of the sea, all kinds of burden, feared for its power for evil. When, during the past month, the curtailment policy instituted by the producers began to make itself felt and a more favorable copper report was assured, it might have been expected that the copper situation would have been a general centre of interest and that the final mastering of the accumulated stock problem would have been general matter of congratulation. The public has ways much like crowds upon the city's streets, and the moment an unusual event is over and things assume a conventional aspect the crowd loses interest and melts into the ordinary passing throng. Analyses of the copper surplus, its causes and its effects, have been many. When the July report showed an increase of but 2,254,661 lb., accompanied by figures from London showing a decrease in visible supply of 10,568,320 lb., or a net decrease in the world's surplus of more than 8,000,000 lb., the public, seeing the end of any acute trouble from present accumulation, turned its attention to speculating upon the legal right of the producers to curtail. While there is no doubt that the authorities at Washington have been watching the copper magnates narrowly, especially in view of the application made by J. P. Morgan and some of his associates some months ago for permission to put the copper merger together, it is plain that the curtailment policy will have to show more signs of concerted action than it does at present to justify any admonition by the Federal Department of Justice. The Imperial Copper Co. of Arizona shut down because the Development Company of America is temporarily unable to further finance the property and meet its requirements for enlarged development. The Balaklala, now known as the First National Copper Co., has shut down on account of smelter-fume trouble. On the other hand, the Phelps, Dodge & Co., Inc., turned out last month more copper than in any previous month of the year. The Calumet & Hecla output for July was 10,507,713 lb., as against 10,742,250 for June. Next month's Association figures should show how fully the agreement to restrict is observed. As these figures cover smelter and refinery output, rather than the actual mine production of each month, a month or two must elapse before results are plain. The meeting of the Copper Producers' Association this month was held with T. L. Livermore in the chair for the last time. It is no small tribute to Mr. Livermore that the members of the Association, though they have known for some weeks of his impending retirement, have not as yet chosen his successor. It is expected that the stockholders of the Miami Copper Co. will in the near future be asked to authorize an increase in the capital stock. Miami has some ambitious plans. The mill is to be larger than was at first planned, some additional ground is to be acquired. There have been some surmises that the increased capital was to be used in taking over the New Keystone Copper, which, like the Miami, is one of the promotions of the General Development Co. This, however, is denied; the present plans do not include the immediate absorption of the New Keystone, though a further increase of stock will probably be made later for this purpose. Miami has a capital of 700,000 shares, par value $5, of which 600,000 shares are outstanding, 88,000 held in reserve against the present bond issue of $1,500,000, and 12,000 remain in the treasury. The bonds are convertible into stock at $19, a large part of the original issue has already been exchanged.

The passing of the Cumberland Ely Copper Co. marks another step in the general progress made toward the inevitable final copper merger that is to come as an evolution. The stockholders of the Cumberland Ely are being asked to instruct the directors to sell all of the property, distribute the proceeds, and wind up the corporation. The rapidity with which copper production and copper properties are concentrating in a constantly decreasing number of hands is marvelous and not appreciated unless the progress of the past two years in this direction is noted. That Nevada Consolidated will be absorbed, even as it absorbed Cumberland Ely, is almost an inevitable consequence. Later Utah Copper will undoubtedly take over Ray Consolidated, which is just now in turn assimilating the Gila. It does not require a very prophetic vision to see a day when the part of the individual in copper mining will be simply the primary exploitation of new properties. The control of the smelters will give to the present powers a whip hand that will not allow any independent producer to grow into a dangerous competitor. In order that the Cumberland Ely shareholders, of whom there are now but a few, may not find themselves sold out without any alternative, the Nevada Consolidated Co. is keeping open its original offer to exchange one share of its stock for three and one-quarter shares of Cumberland Ely.

The Greene Cananea Copper Co.'s output for July was 4,500,000 lb., the best month the property has had under the Cole-Ryan management. The precious metals are of great help of the Greene Cananea; the silver recovered in July amounting to 119,000 oz. and the gold to 545 oz. The rebuilding of the scrap heap which was taken over from William C. Greene is practically complete, though the attention to some further minor details is necessary to economy of operation. Greene Cananea copper costs are between 10 and 11c. This figure must be cut down before any great profit can be earned, and Greene Cananea's $50,000,000 of capital stock must be cut down also before such profits can be distributed as dividends at anything like a satisfactory rate.

The recent shipments of copper matte, received from Africa at Perth Amboy, and which were erroneously thought to be the first consignment of a large accumulation of metal produced by the Tanganyika Concessions, Ltd., has made this concern a subject of some attention. 'Tanks,' as the issue is known on the London Stock Exchange, owns an extensive property in the Belgian Congo, or rather it operates such property through a Belgian corporation, the Union Minere du Haut Katanga, 45% of the stock of which is owned by the Tanganyika Concessions. The properties, consisting principally of three mines, the Kansanshi, the Star of Congo, and the Kambove, are now connected with the east coast by rail. The present management estimates an annual production of 135,000,000 to 200,000,000 lb. of copper

within three years. A smelter is being erected at the Star of Congo, and general equipment provided to insure a low-production cost. The freight item is the company's real problem. The rail haul to Beira on the coast is a long one, and no economy of operation can so cut this item that it will not absorb a material part of the profit on the metal output.

While the Cobalt share market refuses to be stirred into life, regardless of whatever stimulant may be applied, there are some really important discoveries being made in the camp. La Rose has opened a rich vein on the Princess lot. It was found at a depth of 135 ft., is 3 in. wide, and assays 3700 oz. per ton. There is a well defined rumor that the La Rose dividend, some months ago cut from 16 to 8%, is soon to be restored to the original rate. The cumulative effect of these two items was insufficient to start any uplift in La Rose. Cobalt's great dividend payer, the Temiskaming & Hudson Bay, has also made a rich discovery on its property near the Nipissing line, and is sacking some rich ore. The shares, of which there are but some seven thousand outstanding, have a par value of $1, and sell for $100 to $105. The company is building a 60-stamp mill.

A valuable mining concession has been granted to a New York syndicate by the authorities of Asiatic Turkey, subject to the ratification of the Turkish Parliament, in November. The concession permits the syndicate to explore the mineral resources and the oilfields of Kurdistan and the valleys of Tigris and Euphrates. Among those interested in the operations of the syndicate are E. C. Converse, president of the Bankers Trust Co.; C. A. Moore, of Manning, Maxwell & Moore; A. F. MacArthur, president of MacArthur Brothers & Co.; Franklin Remington, of the Foundation company; all of New York. The plans of the syndicate also contemplate the building of a railway through Asiatic Turkey, some 1200 miles long, at an estimated cost of somewhere between $60,000,000 and $100,000,000. The work is to be carried on through the Ottoman American Development Co., a New Jersey corporation, with a nominal capital of $500,000, which has been organized for the purpose.

JOHANNESBURG, TRANSVAAL

Record Yield. — Loss of the Chinese. — Illicit Gold Traffic. — Northern Transvaal's Mineral Wealth.

The gold output of the Transvaal for the month of June has been declared at 625,181 fine ounces, or in value £2,655,602. The contribution of the Witwatersrand was £2,541,584, while the outside districts (Heidelberg, Lydenburg, and Barberton) produced £114,018. Compared with the previous month there is a decrease for the whole Colony of 8989 oz., or £38,183, the Rand's decline being £35,617. When, however, the fact that June was only a 30-day month is taken into account, the return must be considered most satisfactory. The average daily yield for last month was £84,719 as against £83,135 in May and £84,153 in April. The rate of profit earning was £27,750 per day as compared with £27,657 in May. In point of fact the June output was the best ever declared by the Colony for a 30-day month, and the recent performances of the mines, combined with the fact that two or three new and large plants are almost ready to commence working, encourages the belief that the output for the current year (always provided that the native labor position does not become less satisfactory than at present), will constitute a great improvement over the 1909 return. The repatriation of the Chinese laborers who wrought so much for South Africa in general and the Rand in particular, has necessitated the most unceasing efforts to make up for the deficiency occasioned by their departure. At the end of May last the gold mines of the Transvaal had over 200,000 native employees, so that in point of actual numbers the loss of the Chinese has been more than made up by unskilled laborers recruited in Africa; but in so far as efficiency is concerned, the labor forces of the Rand have suffered severely. In order to counterbalance the wastage, natives have been recruited from almost every part of South and South Central Africa. Large numbers have been drawn from the distant North and the majority of these have proved to be inefficient. It is, of course, scarcely to be expected that a raw savage will quickly adapt himself to the intricacies of mine work. Since these laborers sign short-time contracts only, their term is completed just when they commence to do really satisfactory work, and at mines where of necessity labor of this class has been employed, results have by no means been satisfactory. The Consolidated Gold Fields of South Africa subsidiaries have suffered severely through the employment of inefficient labor of late. The profit earned by the eight productive mines of the group last month was £113,170. With the exception of the Luipaards Vlei estate and the Nigel—the two least important producers—the profits in comparison with May are lower all round. An official note attached to the returns states that "This is due to the general shortage of native labor, especially in the case of the Simmer & Jack, Simmer Deep, and Jupiter." There can be no denial of the fact that despite the large number of 'boys' now coming into the Witwatersrand compounds, the labor position leaves a great deal to be desired.

In order to minimize the amount of gold stolen some of the most important mining houses have combined in organizing a staff of thoroughly trained detectives, whose duties will be to watch all persons suspected of illicit dealing in gold and also to visit clean-up and retorting rooms, extractor houses, etc., and in various other ways to endeavor to check the evil and convict culprits. One of the most efficient members of the Criminal Investigation Department of the Transvaal, has been placed at the head of the organization and those responsible for the creation of the new mines staff are hopeful that a large amount of the precious metal, which is today finding its way through illicit channels to the East African coast, Zanzibar, and India, will in future not be lost to the industry. Responsible mining men have at different times expressed the opinion that as much as 10% of the Rand output is being stolen. Since the output is now roughly about 600,000 oz. per month, this would mean about 720,000 oz. (or in value nearly £3,000,000) per annum. This is scarcely believable. Were illicit gold buying and selling being carried on to an extent anywhere approaching these dimensions, the methods of the thieves would surely be detected, and the police courts and goals would be full of those awaiting trial or convicted criminals. Moreover, it is scarcely reasonable to think that the trade is sufficiently well organized to handle such an enormous amount of gold. As a matter of fact cases of gold stealing or illicit gold buying, while not uncommon, are by no means frequent or numerous in the Rand police courts. It is admitted that a certain amount is stolen but it is scarcely possible that anything like 10% of the production falls into the hands of thieves. However, the new staff of mine detectives can undoubtedly do something toward minimizing the illegal trade, and if only one-half per cent is being stolen and one-half of this is recovered, the new organization will afford a profit.

When the railway lines which are now being constructed in the northern Transvaal are completed, industry, both mining and agricultural, in that highly promising but little developed part of the Colony, will be greatly stimulated. One line is to be carried on from Pietersburg to the Limpopo river where the Messina mine, the most important copper property in South Africa, is situated. Hitherto the development of the lenticular deposits at Messina has been handicapped by lack of transport, the property being about 140 miles distant from Pietersburg, hitherto the nearest point on the railway. With a direct line to Delagoa Bay, however, the company will be able to greatly increase production. Apart, also, from the benefits that will be secured to the copper and gold mines, and the farmers of the Zoutpansberg district through having cheap and rapid means of transport, the Selah Railway Extension, which is now being built, should usher in a new industry in the production of mica. There are 60 miles of micaceous country in the vicinity of the Olifants river situated close to the proposed route of the new line. Much of this mica is said to be of good quality and preparations are being made to work the deposits on a large scale when the new line is opened.

BUTTE, MONTANA

Western Federation. — Keating Stock. — Butte Mines. — Davis-Daly.—Philipsburg District.

It looks as if the Western Federation of Miners proposes to wage war on the properties in the Lake Superior district, the object being to compel the mining companies of Michigan to pay the same wages as paid by the Amalgamated company in this district. A few weeks ago the story was given out that the Western Federation in ordering that an assessment of day's wages be levied on every miner within the organization was for the purpose of fighting the Amalgamated, a report which caused much surprise and comment in view of the fact that everything is peace and harmony between the miners and the big concern operating in this district. However, the whole matter has been set at rest by the return of the delegates, who declare that the assessment is for the purpose of organizing the Lake Superior district and requiring that the Calumet & Hecla and other companies pay the same wages as the Amalgamated, thus placing the big companies of the Lake district and the big companies of this district on the same footing in the competition of the production of ore.

The Keating Gold Mining Co.'s stock is soon to be listed on the Boston curb and there is a rumor that a dividend will be declared before the close of the year. A contract has just been signed whereby the East Butte agrees to treat all the ore of the Keating for the next three years. Heretofore the company has been limited in its ore shipments to the amount of ore other smelters would take for fluxing purposes, and it has not been able to ship more than 50 tons per day. The shipments are to be increased to 100 tons per day, and it is expected that later they may be further increased. The East Butte needs a considerable quantity of iron ore for fluxing, and as the Keating runs high in iron the contract will be an advantageous one for the East Butte, while it is stated that the iron in the Keating will almost pay for the smelting. A gold value of $19.20 per ton has been announced on some shipments lately made. The East Butte Copper Mining Co. is now giving up practically all of its smelter to the treatment of custom ores. The company is carrying on extensive development, and the ore going to the smelter at present is only that which is hoisted in connection with this and what is required to keep the smelter supplied after the custom ores are cared for. The Butte-Ballakiava company, while in a position to increase its shipments, has announced that it does not propose to do so under the present conditions of the copper market. At the present time it is shipping about 125 tons per day with an average of about 8% copper in addition to a good silver content. The Tuolumne Copper Co. continues to ship about 100 tons of ore per day and at the same time do a considerable amount of development. Like other independent companies, the Tuolumne is not making any effort to hoist any large quantity of ore under present copper market conditions.

The Corbin-Pennsylvania company at Corbin, which is a short distance east of the Alta and on the same vein, is doing a large amount of development with good results. This property was worked to a considerable extent some years ago, but operations were suspended owing to a lack of capital. When the Corbin-Pennsylvania company took the property the old shafts and workings were cleaned out and some excellent veins opened. In one of the veins chalcopyrite ore assaying more than 6% copper and 12 oz. silver per ton was cut. The Boston & Corbin company is reported as doing some fine work in sinking. During the month of July a little over 100 ft. was made in shaft sinking. On the 700-ft. level recent driving resulted in opening some good ore.

The latest advices received in this city from F. Augustus Heinze are to the effect that he is in Holland and is not meeting with the success he anticipated in raising money. No one here is in a position to say when he will return. The Colorado mine of the Davis-Daly company is still idle, so far as the hoisting of ore is concerned, and no word is expected for the resumption of active operations until Mr. Heinze returns. The tramway from the mine to the Northern Pacific railway tracks is connected, and when word does come to commence shipping ore to the Basin concentrator there will be little delay in obeying orders. Word comes from the Philipsburg district that a merger has been effected between the Shakespeare Gold Mining Co. and the Mount Royal Mining & Reduction Co., by which the latter company secures title to all the mines, mining prospects, and water rights of the former company. The Shakespeare is one of the oldest gold properties in the west and was owned by New York capitalists. It possesed a great record as a producer several years ago, smelting returns of many cars being from $19 to $100 per ton. A fault in the formation was met which cut off the vein and shipments ceased, the mine eventually falling into the hands of banking interests and capitalists in New York for money loaned to keep up development searching for the lost orebody. A few months ago the lost vein was found. The new find in connection with the old workings shows an estimated tonnage of nearly 10,000 tons of ore, besides a large amount on the dumps. A compressor plant and air hammer-drill have been ordered for the mines of the Mount Royal company which are silver-copper properties similar to the well known Granite Mountain mine which has produced $32,000,000 and which is a neighbor of the Mount Royal.

SEATTLE, WASHINGTON

Alaskan Discoveries. — Kotzebue Sound. — Koyukuk.

News of placer gold discoveries in the lesser known regions of Alaska has been unusually frequent in the last few weeks. Details are meagre, but enough is authentic to promise a period of active prospecting and considerable production next year. The chief regions from which news comes are the Kobuk-Noatak, adjoining Kotzebue sound in the northwestern part of the territory, the Koyukuk valley, immediately to the east, and the Kuskokwim, south of the Yukon and adjoining the Innoko and Iditarod country. All these have been known to be gold bearing for several years, and the Koyukuk has produced quite heavily. They are rather inaccessible, and for that reason have been neglected by prospectors. The Geological Survey has foreshadowed important discoveries in all three regions, and now has a party in the Kobuk district. A lively stampede took place recently from Kotzebue sound to Squirrel creek, a tributary of the Kobuk. This was the result of a shipment of $150,000 in gold, the preliminary clean-up from one piece of ground. The gravel is high grade and the pay-streak of considerable extent, but further particulars have not yet been received.

From the Koyukuk some heavy shipments are being made. One group of five men has washed out $210,000 from less than 300 ft. of ground and is now on adjoining property, having mined $30,000 up to the first of June with a large and rich dump ready for sluicing. A number of men are reported to have made 'pokes' of several thousands each from Logan creek in this district. All this mining is in comparatively new territory. There are in the Koyukuk only about 160 men, and miners who know the district well say there is room for several thousand, besides excellent opportunities for dredging and hydraulicking enterprises. The camps are about 600 miles up the river from the Yukon. When the Iditarod stampede took place this spring it was generally predicted that many of the old-time prospectors would work their way from there over the divide into the Kuskokwim valley. This is the least known region south of the Yukon, but its great area and lack of transportation has held pioneers back, though the predictions have now come true. There are more men in the valley than ever before. One man who went in last season came out this spring with $4000 that he had washed out himself, and after buying a year's supplies went back without telling his destination. Reports are beginning to filter out of other discoveries, and there is also news of an important gold quartz find on the river. Watchful Alaskans earnestly believe that this is to be one of the next big gold producing regions of the territory, with probabilities also favoring the Koyukuk, Kobuk, and Noatak as the other areas.

General Mining News

ALASKA

The official report of the Alaska Treadwell Gold Mining Co. for the month ended July 15, is as follows:

Mill time elapsed, 30 days; running time, full mill; 240-stamp mill 28 days, 3 hr., 43 min.; 300-stamp mill, water power 28 days, 3 hr., 10 min. Tons of ore crushed, 240-mill, 32,452; 300-mill, 44,660. Tons concentrate saved, 240-mill, 600; 300-mill, 750.

Estimated gross value of free gold	$115,126.45
" " " " concentrate	77,900.62
" total production	$193,027.07
" " realizable value	$183,775.81
Operating expenses	87,299.37
Net operating profit	$96,476.44
Construction expenses, etc	18,576.57

Yield per ton of ore milled, $2.50.

Development work: 748 ft.; 1250-ft. level, 66 ft. in vein matter; average assay value, $1.11; 1450-ft. level, 579 ft. in vein matter; average assay value, $3.30; 1600-ft. level, 103 ft. in waste.

The official report of the Alaska Mexican Gold Mining Co., for month ended July 15, is as follows:

Mill time elapsed, 30 days; running time, full mill of 120 stamps, 28 days, 17 hr., 57 min.

Tons ore crushed, 18,307; tons concentrate saved, 360.

Estimated gross value of free gold	$35,054.13	
" " " " concentrate	35,131.03	$70,185.16
Less amount due United company		906.87
Estimated total production		$69,278.29
" " realizable value		$66,767.75
Operating expenses		26,946.33
Net operating profit		$39,821.42
Construction expenses, etc		6,974.72

Yield per ton of ore milled, $3.78; stock of broken ore increased 85 tons.

Development work, 508 ft.; 1100-ft. level, 169 ft. in waste; 1200-ft. level, 140 ft. in vein matter; average assay value, $2.27, 50 ft. in waste; 1320-ft. level, 149 ft. in vein matter; average assay value, $2.02.

ARIZONA

COCHISE COUNTY

Kirk L. Hart, manager for the Cochise Copper Co., operating at Johnson, has made arrangements for the resumption of work at the company's ground. At the present time the workings at the mine consist of a 550-ft. shaft with a number of drifts and cross-cuts to the ore. The intention of the management is to sink to the 1000-ft. level and develop the vein at that depth.——The shaft at the Centurion in the Dragoon district, has opened a body of ore at a depth of 410 ft., and a station will be cut at the 425-ft. mark and the vein prospected.

GILA COUNTY

(Special Correspondence).—Due to the fact that only one man can work at a time in the Blackbird shaft at the Arizona-Michigan property, the shaft is being driven alternately with the cross-cut at the 405-ft. mark. It is about 430 ft. deep, the formation being a shale that has obtained for the last 50 ft. Work is progressing at the rate of three feet per day. The cross-cut north to the Old Dominion vein has progressed about 15 ft. and is approximately 4 by 7 ft. in cross section. Both are being driven under contract, at a price of $8 per foot for the shaft and $5 per foot for the cross-cut.——The 14th churn-drill hole has been finished at the Live Oak property, at a depth of 375 ft., having shown a thickness of 120 ft. of ore. The 15th hole is 340 ft. deep and still in the oxide zone, where silicious ores are being cut. The 16th hole, at a depth of 280 ft. is also in the oxide zone. The 17th hole, at a depth of 115 ft., is in the unmineralized capping.——Work at the Warrior mine is continuing westward on the 300-ft. level. A drift is being driven along the foot-wall of the ore-bearing trough, and some time ago a cross-cut was run to cut the orebody. This was driven for 50 ft., and cut 20 ft. of vein matter, 4 ft. of which was high grade.

Globe, August 13.

MOHAVE COUNTY

(Special Correspondence).—S. C. Bagg and associates, have given a lease and bond on their Cyclopic group of claims in Gold Basin. The lessees have started a new shaft and have a promising gold showing.——The Golden Trail group, in the San Francisco district, has been acquired by a group of Utah capitalists.——An increased force of men is being employed at the La Garcia mine in the Black hills. Development will be advanced on a larger scale and the output of ore increased. Regular shipments will be made to the Humboldt smelter.

Kingman, August 15.

PINAL COUNTY

(Special Correspondence).—Ray Consolidated is now working 1200 men at the mine and mill. About 600 men are working underground and about 1000 tons of ore are being placed on the stock pile per day. Only six drills are operating on prospect work. Most of the steel work for the concentrating section of the mill at Winkleman is in place.——At the property of the Copper Creek Mining Co., about 30 miles southeast of Winkleman, work is being devoted to the completion of the tramway to Mammoth and the erection of a smelter. A 75-ton reverberatory furnace and a 75-ton water-jacketed rectangular matting furnace will be installed. Present plans also include the erection of a 150-ton converter plant. Part of this equipment has recently been laid down at Winkleman, and is now being hauled to the property. The furnace will be equipped to use crude oil and a boiler plant will be added to utilize the waste heat. Pending the completion of the smelter and some minor changes in the concentrator, work at the different mines of the company is not being rushed.

Ray, August 13.

YUMA COUNTY

B. F. Hall, of New York, has purchased the controlling interest in the old Desert mine, two miles north of Vicksburg, and will start the 10-stamp mill on the dump which contains enough ore to keep the plant busy for the next two years.

CALIFORNIA

CALAVERAS COUNTY

The mill at Sheep Ranch is only running two shifts owing to the lack of water, though the cyanide plant is to resume operations shortly.——Work has been suspended at the Washington mine, in the Indian Creek district, for a few days owing to a break in the compressor.

INYO COUNTY

The assessment work at the Copper Queen claims, in the Oasis district, has been completed and some high-grade copper ore opened. The Schwab property to the south of this group is working 18 men and opening a large deposit of copper ore.

KERN COUNTY

The Harris Reeves company, of Los Angeles, has commenced operations on the property of the Arondo Mining Co., of which W. H. Miller is manager. This mine, situated in the Argus range, was discovered and developed by Gilbert S. Dean, formerly half-owner of the Dean & Jones mine in the Slate range. The Arondo mine is equipped with Cornish rolls and a 50-ton cyanide plant and has been a steady producer for several years. During the past winter, which was usually severe, the six-mile pipe-line supplying water to the mill was frozen thereby crippling the production to

such an extent that the mine became financially involved. The present work is being done with a view to solving the financial situation. Conway & Rinaldi have contracted to haul freight to the mine and have taken out an initial shipment of five tons of machinery and supplies.——The Sidney group, six miles south of Randsburg in the Stringer district, has completed a milling of about 30 tons of ore at the Phoenix mill near Johannesburg. This is the second shipment of ore made from the property during the present year. This mine was developed by D. V. A. Williams, and has produced several pockets of high-grade ore. The workings extend to a depth of 300 ft., and the mine is equipped with a hoist and air-drills. Albert Burcham is in charge.——The Merced milled 24 tons of ore which is said to have plated about $100 per ton.——Watchman brothers, leasing on the 100-ft. level of the Butte mine, recently cut a rich lens of ore, said to assay $200 per ton.

NEVADA COUNTY

(Special Correspondence).—The Empire Gold Mining Co. is rapidly completing its cyanide plant in which two Oliver filters will be installed early in October.——The raise from the adit at the Jenny Lind is nearing the channel, and the management is hopeful of commencing early production. Joseph Bartell is superintendent.——The south drift from the 1100-ft. level of the Pittsburg has opened the shoot for a distance of 150 ft. Assays run over $10 per ton, and the grade is improving. Ten stamps are running steadily.——The 5-ft. vein on the 800-ft. level of the Champion is showing excellent ore, and the company is arranging for more extensive work from this point. It is possible that a new shaft, above the Providence mine, will be put down next year. Edward C. Uren has been appointed manager.——Arrangements are under way at the Erie mine for heavy production.——It is stated that the Los Angeles interests who recently took over the West Point and Mitchell mines, at Deadman Flat, will commence activites before the end of the month.——It is understood that the new operators of the Murchie are anxious to unwater the shaft, but are unable to secure power, because of lack of water.

Grass Valley, August 15.

Good progress is being made at the Cassidy, near Grass Valley, the shaft being down 155 ft., and progressing at the rate of 6 ft. per day. The shaft has run out of the vein but is expected to pick it up again within the next 50 ft. as the ore is pitching toward it.——A fire which started from the sparks from the engine in the 10-stamp mill at the Birchville mine, two miles from Graniteville, completely destroyed the plant, causing a loss of $40,000 and throwing about 100 men out of employment.

RIVERSIDE COUNTY

(Special Correspondence).—The Gold Park Consolidated Mines Co., operating 70 miles from Banning, on the Southern Pacific, has let a contract for the sinking of its shaft from the 170 to the 500-ft. level. A cross-cut at the 130-ft. level showed the vein to be 60 ft. wide. There are about 1400 tons of good-grade gold ore on the dump, and the showing in the workings is promising. This company is operating two claims, the Black Warrior and the White Warrior. Plans are being made for a small mill.——C. C. Porter, of Los Angeles, has taken a lease on a 7000-ton dump near Leastalk, and has installed cyanide equipment. The ore averages $5 per ton and a saving of 80% is being made.

Banning, August 15.

SAN BERNARDINO COUNTY

The Precious Metals Development Co., operating seventeen miles from Silver lake, is having trouble in its mill on account of a lack of water. The property is developed by a 770-ft. adit, 140-ft. shaft, and 85-ft. shaft, with over 2000 ft. of work in drifts and cross-cuts. About 100,000 cu. ft. of ore, of an average value of $30 per ton in gold, has been developed. The commercial ore varies between two and three feet in width. A cyanide plant is planned for the future.

SHASTA COUNTY

The Old Spanish mine, six miles from Redding on the old Shasta road, has been taken over by James Salee and will be reopened.——The third furnace at the Mammoth plant, at Kennett, has been blown in and the bag-house is successfully handling the smoke from the three furnaces.——Work at the Balaklala smelter, at Coram, is being advanced rapidly and it is hoped to have the Cottrell plant finished by October 1.

SIERRA COUNTY

Good progress is being made in reopening the old incline shaft on the North Fork placer, at Forest, to tap the Uncle Sam vein. The incline has been cleaned out and retimbered to a point 550 ft. from the portal.——The main working adit at the Omega is being driven steadily ahead and the deposit of gravel extensively opened. A number of breasts will be driven as soon as the fall rains furnish enough water to wash the gravel, when a force of 150 men will be employed.——Fitzgerald & Coglan are experiencing considerable delay in getting in their pipe line for the hydraulic power plant on the middle Yuba river, though the compressor has been ready for operation for some time. The owners of the property are figuring on a mill and it is probable that it will be installed this fall.——Fifteen tons of

mining machinery has been shipped to the Primrose mine in Hog canyon.——George E. Turpen has secured a bond on the Carson claims in Slug canyon. A small shaft has been sunk on the shoot and a little driving done on the vein which is east of the serpentine belt.

TUOLUMNE COUNTY

(Special Correspondence).—It is reported that a rich find was recently made in the Shawmut mine. Repair work is now in progress in the lower levels and until completed only 40 stamps of the big mill will be kept in operation.——A pipe-line is being laid to convey water to the Dutch and Sweeney mines.——Harry Shaw and Thomas Doyle have found encouraging prospects in their gravel mine situated one-half mile from Columbia, and are at present endeavoring to connect with an old adit for the purpose of draining the basin where the gold-bearing gravel lies. This has been attempted in former times by others, who abandoned the work on account of the large amount of water.——The Gold Ship Mining Co. is carrying on work at its gravel property in the Groveland district. The Corcoran Flat adit is being cleaned and will be driven to the north end of the claim. It is said that rich gravel was exposed

In this adit by the early-day miners who worked the property, but was left owing to the inadequate machinery then in use. The present company contemplates installing complete equipment in the near future, and will use electric power.

Tuolumne, August 12.

COLORADO

CHAFFEE COUNTY

The fourth shipment of gold from the Cache creek placers this season has been made. Ten thousand dollars in bullion was carried by three men, under heavy guard, from the works of the company to Granite, a distance of three miles, where it was shipped on the Rio Grande train to the mint at Denver. This makes the fourth shipment of the season of an aggregate value of $50,000. This is the placer which is believed to have received its rich gold deposits from the Lost Canyon mountain, upon whose peaks there are being opened some valuable gold leads. Several nuggets of various sizes have from time to time been found on this mountain, but so far the veins prospected have been small, but exceedingly rich.

CLEAR CREEK COUNTY

(Special Correspondence).—The Capital Mining & Tunnel Co., operating on Griffith mountain, has decided to grant a number of leases on the west drift of the Aetna vein. A number of applications have been received, the first block of ground having been alloted to H. Ratholz & Co. In the east drift on this vein a streak of ore 6 ft. wide is opened that mills 9 oz. gold per ton. N. M. Brady is manager.——Alkire & Co., leasing on the Bismark vein through the Hercules level, are shipping ore that mills 320 oz. in silver per ton.——R. Sartorl, leasing on the same property, forwarded a shipment last Saturday that milled 514 oz. silver. A. Erickson, also operating under lease, sent down 8 tons that brought 290 oz. silver per ton.——The Temple electric-drill for the Reliance Gold Mining Co., arrived last week and has been taken to the seat of operations. A. W. Longhi is manager.——Excitement on Bard creek, at Camp Beshears, was stimulated owing to a discovery made at the Roepper property. In the bottom of a 10-ft. prospect hole a 7-in. streak of ore was found that contains free gold. Tests run as high as 17 oz. gold per ton. James Beshears is the owner.——The machinery for the Bard Creek Mining Co. arrived the latter part of last week. It will soon be ready to put in operation. F. Nelson is manager.——Report is current that Denver capitalists have taken a bond and lease upon the Virginia City mine. The option calls for $75,000, the first payment to fall due September 1. F. A. Maxwell is owner.——The Navarrio Mining & Tunnel Co. has been incorporated and work has been put under way in the driving of an adit that is to intersect at depth the entire vein system of Lincoln mountain. C. E. Smith, of Empire, is manager.——It is reported that the Ramsdell Gold Mining & Milling Co. has been thoroughly financed. The Market adit will be continued for some distance. G. W. Teagarden, of Denver, is manager.——The heading of the Homestake adit is still in vein matter. The lode being penetrated is the Golden Jack. A. L. Stephens is manager.

Georgetown, August 13.

GILPIN COUNTY

(Special Correspondence).—A local pool has taken a lease upon the Avon mill, and the machinery is being overhauled. The plant will be run upon ore from the San Juan vein, operated through the LaCrosse adit.——Production is again in order from the British mine in Lake district. The entire workings have been cleaned out and retimbered.——The shaft on the Argo mine has reached a depth of 330 ft. Before any driving is started it is proposed to sink to the 400-ft. level.——On the Gunnell mine Shinher & Co., of Black Hawk, have taken a lease on the Fagan vein. A streak of ore 3 ft. wide is being exposed on the 120-ft. level that is worth $12 per ton in gold.——Johns & Oliver, leasing on the Mitchell mine, have started work on a shaft-house, and will install machinery. Miners are at work in various parts of the property making ready for a steady production.

Central City, August 13.

OURAY COUNTY

The adit of the Wanakah Mining Co. opened a large vug 113 ft. from the surface on the Finance claim from which a large amount of carbonate ore assaying from $30 to $500 per ton is being taken.——Paul Walker and partners, opened a 5-in. streak of gray copper ore in a 2-ft. vein at their Kansas City group.

SUMMIT COUNTY

Preparations are being made at the Wellington mine, in the Breckenridge district, to sink a new 3-compartment shaft. Over 1400 tons of ore and concentrate were shipped from the recent mill-run.——Work has been resumed in the North America adit of the Mary Verna Mining Co., a contract for 1000 ft. of driving having been let. This will cut several well known veins and complete the adit which will then be 3700 ft. from the portal to the face.——A vein of high-grade ore has been opened by Dan Dean on his claims at the head of Illinois gulch.

TELLER COUNTY

The Banner property on Beacon hill, situated below the El Paso has been started by the Union Leasing Co., holding a long time lease. A complete new plant has been installed, consisting of hoist and boilers and an electric compressor. The present depth of the Banner shaft is 375 ft. and it will be sunk 200 ft. Besides this work, the leasing company will drive several cross-cuts in going down.——On the Half Moon claim on Gold hill, H. P. Reiton, the lessee, is driving south on the first level for a junction of two known veins. One of the veins has been opened on surface, while the other vein is open on the same level. The cross-cut has been run 45 ft. and according to engineer's measurements the junction should be close. One of the veins crosses from the Geneva claim.——Andrew Larson and W. Anderson, operating the Brooklyn claim, blocks 230 and 237 of the Stratton estate, shipped two cars of ore. This was mined at 25-ft. depth working in the old Reiton shaft. The body is 6 ft. wide and averages three ounces. This vein lies next to the Eagles dike, which runs from Altman down through the Eagles and thence south. At places on this dike where stringers and veins cross it, rich ore has been found.——The re-timbering of the Granite shaft, or the Coin shaft, as it is better known, will be completed about September 1, if present progress is kept up, and the work is continued without trouble. The vein, known as the McCarthy vein, opened in the upper Granite, has been found in the deep levels working through the Coin shaft. This vein has netted more than $1,000,000 to the owners of the Granite company. It is 4 ft. wide and is rich.——The quarterly report of the Doctor-Jack Pot Mining Co. has been received by stockholders, and on the whole shows the condition of the company to be very good. There are 16 sets of lessees working on the property, the majority shipping ore. During the last quarter 2100 tons of ore was sent out, the average value estimated at more than an ounce.——Frank Seeley, lessee on the Nighthawk property on Bull hill, one of the Stratton estate properties, has installed a plant of machinery, consisting of a hoist and boiler, and shipments from the mine will begin immediately.

IDAHO

SHOSHONE COUNTY

(Special Correspondence).—The Caledonia Mining Co., operating at Wardner, is shipping about 800 tons of ore per month, which is divided between the American Smelting & Refining Co. smelters at Tacoma, East Helena, and Colorado. The bulk of it averages 75 oz. silver, 15% lead, and 2 or 3% copper; part of it, however, has sampled 45 to 48% lead, and 65 to 75 oz. silver. Charles McKinnis, the manager, states that work has commenced on a 2800-ft. cross-cut that is intended to strike the orebody 660 ft. below the lowest workings. An electric-driven air-compressor has been installed in Deadwood gulch, where the adit begins. When this work is finished it will be unneces-

sary to hoist the ore, and the present 2½-mile haul to Kellogg will be stopped, as the adit will have railroad connection. E. D. Booth is foreman at the mine.

Mining companies operating in northern Idaho have sustained severe losses by forest fires the last 60 days. The Western Pine Manufacturers' Association, and the Northwestern Forestry and Conservation Association, have urged the President and the Secretary of War to send Federal troops into the national forest reservations to fight fires. Near Murray, an area of 40 square miles of timber land has been devastated by fires, which also destroyed buildings, flumes, and appliances owned by mining companies. Employees of the Orofino, Black Horse, Paragon, Monarch, Granite, and Allie mines, under Mr. Williams, Forest Ranger, from the Eagle sawmill, fought the flames for a week, while a force of 20 men from Murray fought the fire at Butte creek and succeeded in turning it. It is now within eight miles of Murray. Veteran prospectors in northern Idaho say that no fire of equal destructiveness has swept over the Shoshone district since 1864, when Federal Governmen employees, engaged in building a wagon-road and forts, started a blaze to drive the Indians and wild animals out of the territory. The fire got beyond control and laid waste many sections of timber land.

Wardner, August 12.

MISSOURI

NEWTON COUNTY

(Special Correspondence).—Potter & Buskett have opened a good deposit in the vicinity of Tipton Ford, southeast of Joplin, the lease lying near the famous old Gilt Edge property which produced wonderfully in the early days. The ores marketed here ran 62% zinc. The present developments were made by reopening an old tract which was worked to a limited extent in the early days and then abandoned, the lead only being mined while the zincblende was left untouched. There is as a consequence a large dump pile rich in blende which will be worked by the operators. The deposit is found at 70 ft. and the drifts so far run show a 20-ft. face. There have been five drill-holes put down blocking out the mineral.——In the Spring City camp, Arthur Scott has sunk a drill-hole on a lease east of the Delta, and is finding a very high grade of lead and zinc, apparently an extension of the find in the Delta where the lead mined has been the best in the camp. The hole entered the deposit at 168 ft. and continued through 8 ft. of rich cuttings, which ran 20%. The lease will be developed by other drill-holes before a shaft is sunk.——The U. G. Wilson company is sinking a shaft on the lease which will make the third one put down. Drill-holes near this showed a blanket formation of lead and zinc. A drift is being extended westward from shaft No. 2 into good ore. Sludge washers are cleaning ore from the refuse of the Wilson mill.——Still further to the south in the old Seneca camp, the Becker mines are producing on first-class ore running 60% zinc. The drifts have been driven recently underneath the former workings and the face has widened until it is now 20 ft. high and 40 ft. wide. Enough ore has been taken from the mine to pay all the expenses of operation to date.——The Granby camp has been extended by the finding of a good deposit some distance southeast of the old camp. The ore was found on the Spangle & Fischel land and occurred practically from the surface down to 50 ft. The shaft will be sunk to 100 feet.

Tiptonford, August 12.

MONTANA

LEWIS AND CLARK COUNTY

(Special Correspondence).—The Northwestern Metals Co., which purchased the site and buildings of the old Steadman foundry, at Helena, is remodeling and re-arranging the plant with the purpose of installing an electrolytic plant of 100 tons capacity, to treat refractory ores containing gold, silver, lead, zinc, and copper. The plant is to be operated under the Baker-Burwell patents. The equipment, which has been ordered, is intended to be installed and ready for work by February 1. It will consist of a crusher, rolls, dryer, chloridizer, and electrolytic cells. The process is to consist of crushing to 20-mesh, drying and chloridizing by dry chlorine gas, to be produced electrolytically from salt solution. The chloridizing is to take place in a revolving tube-mill, the pulp to pass thence to concrete leaching vats, and it is claimed the metals can be precipitated as refined metals. It is asserted that by thorough experimentation in a smaller mill of this kind successful work was performed and a high recovery of the metals was made. M. L. Hewett, A. W. Burwell, and C. C. Titus are actively concerned in building the plant.

Helena, August 12.

NEVADA

ESMERALDA COUNTY

The junior class of the Mackay School of Mines, University of Nevada, completed at Goldfield its summer school work in mine surveying and mining field geology. The surveying consisted in triangulation, linear and topographical surveys, the running of levels, solar and Polaris observations for meridian. Underground, four levels were surveyed and the main shaft of the Red Top mine was plumbed. Three patented mining claims were 'tied in,' and missing corners reset according to patent survey description. The surveying was in charge of H. P. Boardman. The field geology consisted in mapping approximately 18 square miles in the vicinity of Goldfield, a plane table survey of a mining claim on Columbia mountain, the mapping of the underground geology, and the preparation of structure sections of the Red Top mine. The geological work was in charge of J. C. Jones. The students were encamped in the field eight weeks.——The period of comparative inactivity that has characterized the Florence operations is apparently at an end and extensive development will now be undertaken in the lower levels of the mine.——The new station at the 540-ft. level of the Cherokee lease on the Atlanta ground has been completed and development will be advanced from that point.

HUMBOLDT COUNTY

(Special Correspondence).—The output of the National Mining Co. for July, amounted to $280,000. The new mill has been practically completed and will commence production with the completion of the tramway from the mines to the plant. On the Stall lease the shaft is down 400 ft. and is being sent deeper. The small mill is running on bonanza ore, the lower grade being stored for future treatment. The ore in the bottom of the shaft is excellent.——The English capitalists owning the Darby mill at Mazuma, and the Florence lease near Vernon, have acquired the Big Bug claims, adjoining the Mammoth, at Farrell. Development will commence immediately. M. Gillespie is manager.——The Garwood lease is arranging to commence activities on the Faywood-National property. A long adit will be driven to open the veins disclosed in surface workings. James Ritchie is superintendent.——The Gold Note Consolidated Mining & Milling Co. has been formed by New Yorkers to acquire the principal mines in the old camp of Kennedy, 60 miles from Winnemucca. The holdings comprise 1600 acres of mineral lands, together with a 20-stamp mill, and a small Huntington plant. It is planned to work the properties principally by the leasing system. Paul Klopstock is manager.——Throughout the National and Seven Troughs districts mining is active and many of the properties are showing exceptionally well.

Winnemucca, August 12.

WHITE PINE COUNTY

The first of the two new steam shovels of the Nevada Consolidated Mining Co., for the new Liberty pit, has arrived, and been placed in operation at the mine.——The cross-cut from the Eureka shaft of the Ely Central is out over 100 ft. while the shaft itself is nearing the 600-ft. point from which another cross-cut will be started.——At the Giroux the only exploratory work at present is that carried on by the three churn-drills, but the management is preparing to further develop the Alpha orebody at an early date.——The ore-bins for the new mill of the Amal-

gamated Mines Co., near Osceola, are in position and the heavier timbers for the upper portion of the plant have been installed. The work of constructing the plant is under the supervision of R. L. Coulthard, millwright for the Traylor Engineering Co., which has the contract for the erection of the mill.

UTAH

JUAB COUNTY

What is believed to be the same body of ore from which the Colorado has been shipping for years, has been cut in the drift on the 350-ft. level 30 ft. below the rich orebody. The ore was found 350 ft. from the endline of the Sioux Consolidated which has the ore at a depth of 450 ft. ——Suit has been filed in the district court by the Beck Tunnel Mining Co., against the Uncle Sam Consolidated Mining Co. The plaintiff secured a temporary injunction. It asks for $300,000 damages for ore alleged to have been taken from the Cyrus Oliver claim adjoining the Humbug.

SALT LAKE COUNTY

The Reeds Peak Mining Co. is working six men at its property in the big Cottonwood district.——The Carbonate Mining Co. is completing its tramway which will carry the ore for shipment to the smelter.——At the Cardiff 125 tons of ore per month, which assays $50 to $60 per ton, is being shipped. The company is building new houses for the accommodation of the men and adding to the force working on development.——Recent work at the Baby McKee has opened an 8-in. vein that assays $50 per ton.—— The Neva Mining Co. has opened a vein that assays 30 to 40 oz. silver with 40% lead and a small amount of gold.

WASHINGTON

FERRY COUNTY

The Pearl Consolidated company paid its fifth dividend on August 11. It amounted to $19,707.11, or one cent a share. This brings the total of dividends to date by this company to $108,389.05. The company is owner of the Lone Pine-Pearl-Surprise group in Republic camp, for the last seven months operated by the Republic Mines Corporation, J. L. Harper general manager. Its earnings are from a 50% royalty on all shipments made by the Republic Mines Corporation and are being applied in the form of dividends to a liquidation of its capital stock. The lease and bond are for $225,000, of which, as evidenced by the dividends, half has been paid. The lease still has 18 months to run. The Republic Mines Corporation began the payment of regular monthly dividends from the profits of its lease two months ago. These now total $25,000, and $15,000 was paid a few days ago. This will bring the total earnings of the Surprise mine, which will have been distributed to the shareholders in less than six months, to nearly $150,000.—— The British Columbia Copper Co., of Greenwood, is shipping iron-copper ore regularly from its Napoleon mine near Boyd.

STEVENS COUNTY

(Special Correspondence).—The First Thought mine is situated on the east side of the Kettle river, three miles northeast from Orient, which is on the Great Northern railroad. This mine has been producing ore during the past five years, and belongs to P. Burns & Co., of Calgary, B. C. The property is managed by Alexander Sharp, who employs thirty men, and ships approximately fifty tons of ore per day to the smelting plant at Trail. The ore occurs in an andesite formation, the mineralized body not being limited within defined walls in all places. The analysis of the ore is given as follows: Gold, 1 oz.; silver, 1 oz. per ton; iron, 8%; lime, 10; sulphur, 3; silica, 70; and alumina, 14%. The ore is hauled through a 700-ft. adit, which opens the orebody at a depth of several hundred feet below the apex of the vein. Much of the orebody above the adit-level has been stoped out. A 150-ft. winze has been sunk on the ore from the main level, and a good part of the tonnage being mined is taken from drifts off this winze. Stoped-out chambers off the main adit, and extending 50 to 100 ft. below it, have proved a mineralized body 60 to 80 ft. wide. The ore is transported from the mine to the bunkers at the railroad over a two-mile aerial tramway.——The Swamp King M. Co. is developing a gold property three miles north of the First Thought. This belongs to L. D. W. Shelton, who has bonded it to the Swamp King company, made up of R. M. McIntire and associates. The company has installed a steam-hoist and blower, and has sunk an 80-ft. shaft since March 1. The ore comprises copper-iron sulphide containing gold. In fact, some of the best ore contains sylvanite. Mr. McIntire has a considerable tonnage of iron ore on the dump, and will make a shipment to one of the smelters.——The Kettle River M. Co., situated on

First Thought Mine.

the east side of the Kettle river, opposite Rock Cut, will soon have its concentrating mill ready to operate on galena ore.——The First Thought Extension, which has the same kind of ore as the First Thought, has half a dozen men at work.——J. T. Dolan has been developing for several years his Second Thought group of claims lying south of the First Thought.

Orient, August 13.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—A campaign of diamond drilling is planned for the City of Paris mine at Central. This property has been idle for many years, but is receiving renewed attention, as the No. 7 property is working and a new road has been built to Central.——In Phoenix, during the past week, the regular shipments were made to the Granby and B. C. copper smelters, and from the Snowshoe to the Trail smelter.——The new slime-treating mill at the Jewel mine is in operation. The average ore of the Jewel mine assays $15 per ton. It contains galena, zincblende, iron pyrite, and occasionally ruby silver, telluride, and some free gold, and has proved difficult of treatment. It is thought the new 15-stamp mill with the Nichols process will meet with success.——Water has been turned into the new pipe-line of the Daly Reduction Co., at Hedley. This line will be an auxiliary to the big flume and will supply water for the batteries, boilers, vanners, and cyanide tanks. There are 150 men employed about the Nickel Plate properties, and the new plant, including the Doble wheel, engine, boilers, and tube-mill, is all in and will soon be working.

Rossland, August 13.

MEXICO

CHIHUAHUA

L. T. Bryant is to equip his San Pablo gold-silver-lead mine at San Pedro with machinery for deeper development. The San Pablo adjoins the Congreso mine of the Candelaria Mining Co. and is believed to have the continuation of the Congreso's orebodies. The San Pablo shaft will be 400 yd. from the terminus of the new railroad being built by the Candelaria company to the Congreso mine from the Mexican Northwestern railroad.

GUERRERO

It is reported that the American Smelting & Mining Co. will establish an ore-buying agency at Taxco, and will handle the ore at the patio of the mine.

SONORA

The plant of the Yaqui Smelting & Refining Co. at Toledo, Ures district, 150 kilometres north of Corral, on the Corral branch of the Mexican Southern Pacific railroad, after being shut down for three years, owing to high cost of fuel, is being put in order, as the company expects to blow in the smelter before the rainy season begins. Ore is being shipped to the plant.

Decisions Relating to Mining

Specially reported for the Mining and Scientific Press.

RE-LOCATION OF MINING CLAIM—CONFLICTING CLAIMS

The statute of Wyoming provided that if a locator believes the original location certificate to be defective, he may file an additional certificate, not infringing the rights of others existing at the time of such re-location, and that such re-location will not preclude the claimant from proving the title under the previous location. Accordingly where a valid discovery of a claim was made in 1897, the boundary stated the development work done and the original location certificate was recorded within the time; and in January 1907 the original locators or their assigns filed an amended certificate describing the claim as originally located, and which recited that the amendment was filed without waiver of any previous rights, but to correct errors in the original location, such original location and such re-location gave a prior and superior right to the claim as against a rival claimant who had posted notices and commenced work on a discovery shaft at the time the certificate of re-location was recorded, but where the certificate of the rival claimant was not filed until at least five weeks after the filing of the amended certificate by the original locator or his assigns. The rule is that where the original discoverers and locators have sunk a shaft and each one knows of the existence of mineral-bearing rock in place in such shaft and at the point where the notice was posted, such facts sufficiently show a discovery to support a new location by them at the time of posting the notice. And where a mining claim is re-located by the original locators the boundaries of the new location need not be marked, as required by the statute for an original location, in case the boundaries of the original location are marked and identified, as a locator may adopt the original markings and the boundaries where the exact ground is embraced in both locations and where the boundary posts of the original location still remain, notwithstanding the statute contains an express permission to adopt old boundaries only in case of an abandoned claim. It is also the rule that if a new location of a mining claim by a person holding under a former location is for any reason invalid, the attempted relocation is not an abandoned one or a forfeiture of the former location; and it follows that a deed to a mining claim describing the premises as recorded in the records of a certain named county will pass the interests of the grantors not only under the certificate of the original location as recorded, but also the interest of the grantors in the same claim under a subsequent location. It is also the rule that where location certificates have been on record for several years prior to an attempted location of adverse claims, they take the place of the location notices and render proof of the posting of such notice unnecessary as against any such adverse claimants.

Bergquist *v.* W. Virginia-Wyoming Copper Co., (Wyo.) 106 Pac., 673, Feb. '10.

PROTECTION BY RE-LOCATION

Where a mining claim has been improved by the original locators or their assigns without abandonment, but because of a defect in their original location certificate, the former locators or their assigns have the right to protect their interest by making a new location, if there has been no failure on their part to perform the required development work. So where a corporation acquired all the title of the original locators of a mining claim both under an original and subsequent location it was competent and proper for such corporation to record an additional or amended certificate of location and claim thereby the discovery as of the date of the discovery by the original locators. In such case it is proper to prove that the original locators in re-locating a claim adopted the boundary stakes of the original location.

Bergquist *v.* W. Virginia-Wyoming Copper Co., (Wyo.) 106 Pac. 673, Feb. '10.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

A. H. Heuser is at Greyhound, Idaho.

Herbert L. Eaton is at Liberty, Missouri.

R. P. McLaughlin has been in San Francisco.

C. S. Vearill is at Vancouver, British Columbia.

Ezequiel Ordonez has gone to Stockholm, Sweden.

N. W. Chapman, of Redboy, Oregon, is in Chicago.

Edgar Rickard has been enjoying a vacation in France.

E. M. Stewart has left Ray, Arizona, for Lang, California.

Howard D. Smith has returned to San Francisco from London.

John B. Farish, who has been in San Francisco, has gone to Nevada.

J. C. Pickering is with the Mexico Mines of El Oro, El Oro, Mexico.

S. W. Laughlin, formerly of Golden, Colorado, is now at Butte, Montana.

H. S. Washington will leave New York soon for another stay in Brazil.

Thomas T. Read married Mary Carlton Peck at Pei-tai-ho, China, July 26.

William P. Miller, Jr., has removed from Los Angeles to San Francisco.

H. H. Holbert has left Fruita, Colorado, and is now at Gallup, New Mexico.

R. B. Parke has been transferred from Olongapo, P. I., to Pearl Harbor, Hawaii.

R. P. Wheelock has gone from Searchlight, Nevada, to Battle Creek, Michigan.

Jay Jeffries is superintendent for the Ideal Mining Co. at Custer, South Dakota.

W. H. Weed was in San Francisco last week on his way to the Yellowstone Park.

A. H. Eiftman has returned from Minneapolis and the East and was in San Francisco.

Forest J. Swears is making examinations in the Midway oilfields for San Francisco companies.

R. B. Lamb and B. Binnard have returned from Los Angeles to New York by way of San Francisco.

Mason T. Adams has removed his office from the McPhee building to the Symes building, Denver, Colorado.

E. A. Prentis, Jr., of New York, is now with the Lluvia de Oro mine, at Lluvia de Oro, Chihuahua, Mexico.

Leonard Sivyer, of Los Angeles, has recently examined mines in the Providence range of southern California.

L. S. Ropes and Robert McIntire have opened an office at Helena, Montana, to engage in mining engineering.

G. G. Rockwell has returned from Cuba and is at Ishpeming, Michigan, with the Cleveland Cliffs Iron Company.

J. D. Hubbard has gone East. His address until September 1 will be, care Oriental Con. M. Co., 15 Broad street, New York.

Howland Bancroft has completed his examination of the Deertrail mining district, Stevens county, Washington, and will be at Denver until September 15.

Ivan E. Goodner has left the Bogardus Testing Laboratories at Seattle to take a position in the cyaniding plant of the Alaska Treadwell Gold Mining Company.

Moncrieff Finlayson, of the Royal School of Mines, will leave London in September to examine oilfields in Burma. His address will be care Steel Bros. & Co., Rangoon.

Curtis H. Lindley, John Hays Hammond, James Douglas, J. Parke Channing, H. Foster Bain, W. R. Ingalls, E. W. Parker, J. A. Holmes, and George S. Rice have been appointed by the President as national delegates to the American Mining Congress at Los Angeles, September 26 to October 1.

Recent Publications

BIBLIOGRAPHY OF NORTH CAROLINA GEOLOGY, MINERALOGY, AND GEOGRAPHY, WITH A LIST OF MAPS. By F. B. Laney and K. H. Wood. Bull. 18, North Carolina Geological and Economic Survey. J. H. Pratt, director. Pp. 428, index. Raleigh, 1910.

COAL FIELDS IN COLORADO AND NEW MEXICO. By G. C. Martin, C. W. Washburne, M. I. Goldman, G. B. Richardson, and J. H. Gardner, U. S. Geol. Surv. Bull. 331-C. Contributions to Economic Geology, 1908. Pp. 181, Ill. Washington, 1910.

SIXTH ANNUAL REPORT, DIRECTOR OF SCIENCE DIVISION. NEW YORK STATE MUSEUM. By J. M. Clarke, director, and other contributors. Pp. 229, Ill., index. Albany, 1910. This report includes that of the State Paleontologist and several short geological papers.

COAL FIELDS OF WYOMING. By R. W. Stone, C. T. Lupton, H. S. Gale, C. H. Wegemann, E. G. Woodruff, M. W. Ball, Eugene Stebinger, and A. R. Schultz. U. S. Geol. Surv. Bull. 381-B. Contributions to Economic Geology, 1908. Pp. 186, Ill. Washington, 1910.

GEOGRAPHY OF THE MIDDLE ILLINOIS VALLEY. By Harlan H. Barrows. Illinois State Geol. Surv. Bull. 15. Pp. 128, Ill., index. Urbana, 1910. In this report Mr. Barrows has shown most effectively the influence of geography and geology on the settlement and industries of the area discussed.

DRAINAGE PROBLEMS IN TENNESSEE. By Geo. H. Ashley. Bull. 3, State Geol. Surv., Tennessee. Pp. 74. Nashville, 1910. This is the first of the regular bulletins of the new Survey and includes a preliminary report on certain overflowed lands, written by A. E. Morgan and S. H. McCrory, with a copy of the drainage law of Tennessee.

ORE DEPOSITS OF NEW MEXICO. By Waldemar Lindgren, Louis C. Graton, and Charles H. Gordon. U. S. Geol. Surv. Professional Paper 68. Pp. 361, Ill., index. Washington, 1910. This work is the best general summary of the ore deposits of the region yet printed. It is profusely illustrated and contains a large amount of valuable information.

STRUCTURAL MATERIALS. By E. F. Burchard, A. H. Purdue, J. A. Udden, T. N. Dale, J. H. Gardner, N. H. Darton, E. W. Shaw, W. C. Alden, E. C. Harder, and F. L. Hess. U. S. Geol. Surv. Bull 430-F. Contributions to Economic Geology for 1909. Pp. 148. Washington, 1910. Among the especially interesting papers in this report are an account of the oolitic limestones at Bedford, Indiana, by Mr. Udden, and a paper on the slates of Arkansas by Mr. Purdue.

MINING LAWS OF AUSTRALIA AND NEW ZEALAND. By A. C. Veach. Pp. 180. Washington, 1910. When in connection with the conservation movement the question of revision of the public land laws of the West arose, it was promptly apparent that there was nowhere available adequate data regarding the form and results of various land laws tried out in Australia and New Zealand. Mr. Veach was therefore sent to those countries as a special commissioner to study and report upon their mining and land laws. It is a striking commentary upon the unbusinesslike manner in which appropriations are allotted at Washington, that funds were neither available for the expenses of the trip nor for the publication of the report. Apparently it was considered better to blunder along in the dark and re-try old experiments than to spend money in travel and study. However, the Director of the Geological Survey and Mr. Veach divided between them the expenses of the investigation and a limited number of copies of the report have finally been published as an appendix to the hearings of the Congressional Committee that has been investigating the Department of the Interior and the Bureau of Forestry. It happens in this, as in other cases, that the appendix is more valuable than much of the main report, and if the Investigating Committee has been properly impressed with the work and the circumstances under which it was done, one of their sessions, at least, was well spent.

The Prospector

This department makes a charge of 25 cents to subscribers not in arrears and $3 to non-subscribers for each determination. To ensure promptness in publication of the determinations, payment must be forwarded with specimens.

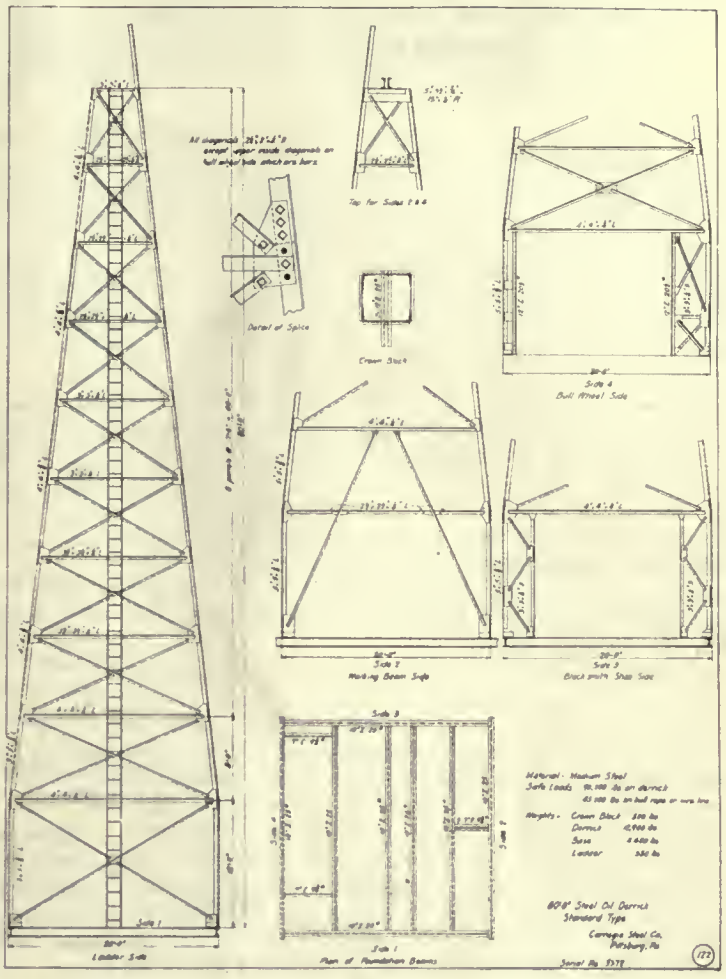
V. V. S., Baker City, Oregon: Pyrite; the color is due to oxidation.

J. G. McP., Hillsboro, New Mexico: No. 1, common brown garnet; No. 2, specular iron, contains neither tin nor tungsten, may contain gold.

F. E. B., Goldfield, Nevada: No. 1, a highly altered acidic eruptive, probably rhyolite; No. 2, a basic eruptive so far altered as to render its original condition obscure.

W. F. C., Battle Mountain, Nevada: This extremely interesting and unusual ore specimen appears to be a breccia in which the outer portions of the larger fragments have been softened and rounded by mineral solutions and the original material replaced by quartz and calcite. In physical appearance it resembles what is commonly known as the 'orbicular' structure sometimes seen in diorite, granite, and some other crystalline rocks.

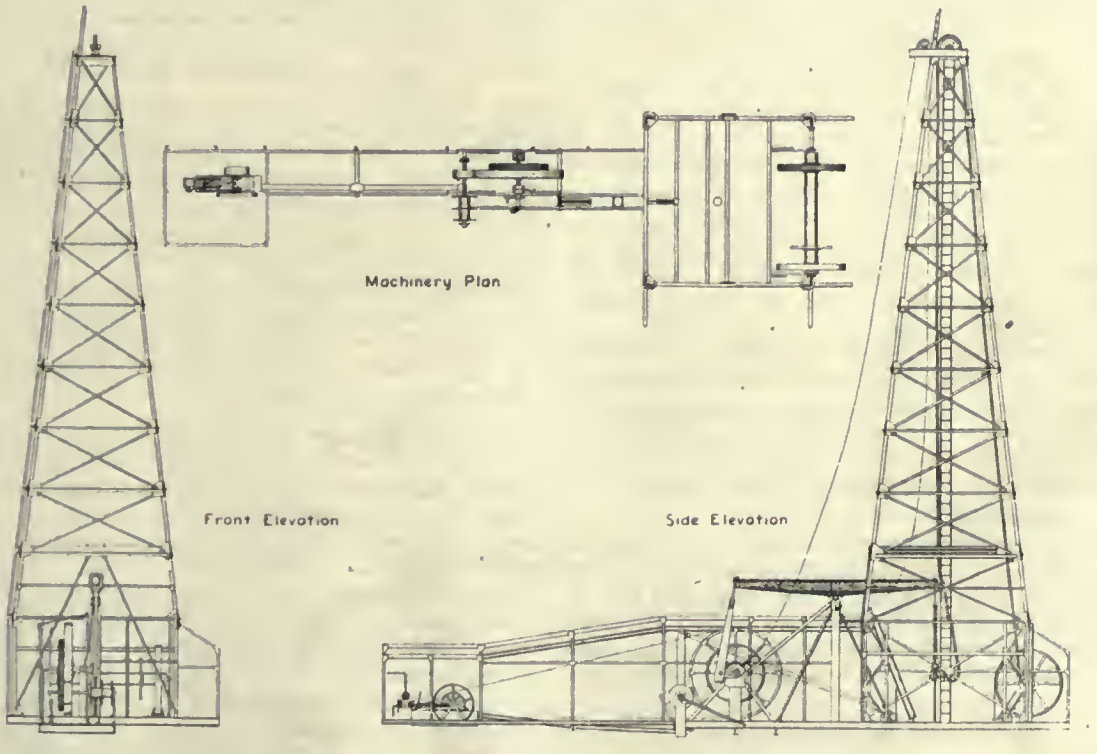
STEEL DERRICKS AND DRILLING MACHINES



Deterioration in the character of the timber available for derrick construction, its increase in cost, and its lack of fireproof qualities, have seriously interfered with its adaptation to present day conditions; besides which, with improvements in tools and machinery the art of deep well drilling has been established more nearly on a scientific basis and there is recognition of the fact that a wooden construction is not adapted to removal and re-use and, therefore, is not economical on a basis of ultimate expenditure. The Carnegie Steel Co., of Pittsburg, Pa., has published a pamphlet pointing out the advantages of steel for the construction of derricks and drilling machines for deep well drilling, and describing certain types. Two types of derricks, the 'Standard' and the 'Oklahoma,' are made. An 80-ft. Standard derrick is illustrated in the accompanying cuts.

The first metal oil-derricks were probably constructed of second-hand steel or iron tubing used in drilling operations, with forged connections and diagonal bracing made of rods and turn-buckles or wire cables, which rendered them advantageous for use in spite of the cost of the blacksmith work necessary. The first derricks built of structural steel shapes, such as are used in buildings and bridges, were constructed on principles of design customary in the manufacture of viaduct, water, and transmission towers with long panels which necessitated the use of scaffolding or gin poles in erection. These did not conform to the type of derrick which is customary in wood and at first did not meet with favor from the drillers. Twelve such derricks were built by the Carnegie Steel Co. for the South Penn Oil Co. and the Carnegie Natural Gas Co. in 1903, for use in the Pennsylvania and West Virginia oilfields. They were 80 ft. high with a 20-ft. base, and provision was made at the top for crown pulleys and at the bottom for wooden bull-wheel supports. They weighed 24,000 lb. apiece and proved to be thoroughly satisfactory after erection, were stiff and steady under strain, and have been removed from their original location and re-erected more than once. Since then new and improved types, such as the one illustrated, have been designed.

The improvements incorporated in these derricks include the reduction of the height of the panels to permit erection without any special equipment in the way of scaffolding and to facilitate the removal of the derrick from place. Complete drilling machines as well as derricks are also now made of steel. In 1907 the first of these were made, being modeled after the regular 72-ft. California type, and since 1908 they have been regularly manufactured.



A NEW METHOD OF AGITATING PULP IN CYANIDATION

By John M. Nicol

Mechanical methods of agitating pulp during leaching with cyanide solutions are being discarded in almost all the great mining centres, because of mechanical difficulties, lack of thorough mixing and effective aeration during the process, and especially of high power consumption. Compressed-air agitation has been widely adopted but also labors under serious disadvantages, due to incomplete mixing, the introduction of atomized oil from the compressor (which causes foaming), together with excessive aeration and attendant losses of cyanide from the last two causes. Experiments carried on by W. C. Paterson with a view to overcoming these difficulties demonstrated the possibilities and advantages of hydraulic methods of agitation, and after numerous tests and experiments by Mr. Paterson, E. E. Burlingame of Denver and other co-workers, an agitator has been evolved based on the principle of a hydraulic ejector. The latest model of this agitator is now being placed on the market by the Hydraulic Cyanide Agitation Co., of Warren, Pa., which controls the United States, Canadian, and Mexican patents.

The agitator consists of a conical-bottom tank similar to those used for air agitation, and fitted with a central circulating tube, which takes the place of the air-lift in the air agitators. The tank is also equipped with an inner annular baffle, which provides a calm zone between the baffle and the tank where no agitation takes place. Comparatively clear solution rises to the top from this annular space. A small amount of this clear solution is drawn off continuously through a flexible decanting pipe and supplies the suction of a small centrifugal pump. This delivers the solution under pressure to a nozzle at the base of the central lift tube. By this means all of the sand and slime is kept in constant agitation, without passing any sand through the pump. Immediately over the discharge of the central lift, a damper and distributer are provided which cause the ascending pulp to be distributed in a radial sheet, which assures a moderate and even aeration. In case additional aeration is required, a small stand pipe is attached to the suction of the pump, and equipped with a valve. By opening this, any requisite amount of additional air can be drawn in by the pump and brought in contact with the pulp during its passage through the central tube. The tanks are fitted with central discharge valves and are equipped for either intermittent or continuous process systems of agitation. The great advantages of the system are: (1) Low first cost, small centrifugal pumps being cheaper than air-compressors, and simpler to operate. (2) Economy in power, it being the lowest in power consumption of all systems of agitation. (3) Lower consumption of cyanide, due to the avoidance of excessive aeration. (4) Absence of 'foaming' which is such a serious trouble in air-lift agitators. (5) The apparatus will permit agitation of almost any range of pulp density or size of sand. (6) The current will start after settling for a number of days. (7) Perfect cross-agitation is provided which will distribute the sand evenly over the whole cross-section of the settling area.

Tests recently made on a working scale have shown the agitation to be nearly perfect, the extraction being as high as 94% in from 12 to 16 hours on gold ores, and from 83 to 90% on silver ores in 20 hours and under. Extensive tests are now being carried on in London and at the Rand, with a view to the erection of a large plant in South Africa.

CATALOGUES RECEIVED

The J. Geo. Leyner Engineering Works Co., Littleton, Colo. Bulletin No. 1017. 'Water Leyner Drills.' Illustrated. 16 pages. 6 by 9 inches.

Taylor Iron & Steel Co., High Bridge, New Jersey. Bulletin 108. 'Tisco Manganese Steel Mine and Skip Car Wheels'. Illustrated. 16 pages. 6 by 9¼ inches.

COMMERCIAL PARAGRAPHS

Edwin Letts Oliver, formerly metallurgist at the North Star mine, Grass Valley, California, has organized the Oliver Continuous Filter Co., with offices at 9 First street, San Francisco, and will devote all his time to the manufacture and sale of the filter invented by him.

The Gallgher Machinery Co., Salt Lake, advises that sales of Callow screens for the month of July included the following orders: 12 duplex Callow screens for the Miami Copper Co., Globe, Arizona; 5 duplex Callow screens for the Real del Monte y Pachuca, Pachuca, Mexico; 3 duplex Callow screens for R. E. Briggs & Co., Mexico City.

One of the recent orders received by Allis-Chalmers Co. was from the Finnish American Copper Company at Helsingfors, Finland. This order was for a complete 'fine' concentrating plant for the extraction of copper, lead, and zinc. There was also included the complete power equipment, made up of boilers, engines, generators, and everything necessary for the entire plant.

The Edgar Allen American Steel Co., recently organized in Chicago, has purchased the Chicago Heights works of the American Brake Shoe & Foundry Co. and the New Castle, Delaware, plant of the Tropenas Steel Co., and after this date the manganese steel business of both the above mentioned companies, also the manganese steel business heretofore conducted in the United States of America by Edgar Allen & Co., Ltd., Imperial Steel Works, Sheffield, England, will be carried on by the newly formed company.

An interesting shipment of mining machinery was made August 3 on the steamer *Hellig Olav* of the Scandinavian American Line by the Ruggles-Coles Engineering Co. of New York. It consisted of two dryers of its class 'A' type, 104-in. diam., 45 ft. long, weighing 115,000 lb. They are to be used in drying magnetic iron concentrates and have a capacity of 35 tons per hour each. These dryers were purchased by Aktieselskabet Sydvaranger, of Christiania, to be erected at its plant at Varanger Fjord, Norway, 600 miles inside of the Arctic Circle.

The Eureka Stone & Ore Crusher Co., Cedar Rapids, Iowa, has recently put a new crusher on the market known as the Mitchell-Eureka. It is of all steel construction. The base is a single open-hearth casting which gives the necessary rigidity and strength. It is reinforced to stand the hardest shocks. The jaw plates are of the best grade of manganese steel. The eccentric shaft, which carries the weight of the pitman, is turned from open-hearth hand-forged steel. By turning a hand wheel the jaws can be opened and closed at will. The toggle plate prevents possible breakage from the accidental dropping of a hammer between the jaw plates. A method is provided for taking up the wear in the bearings. It is claimed that the machine saves 35% in power required by other crushers of like capacity. The bearings are only three in number and are equipped with ring oilers and compression oil cups.

The D. D. Demarest Co., San Francisco, advises that the following are among its recent shipments of mining and milling machinery: One 75-ton silver-lead concentrating plant, Nevada; battery timbers for 60 stamps, Mexico; 5-stamp gold mill complete, Tuolumne county, California; tramway machinery, Vulture mines, Arizona; 150-hp. double-drum electric hoist, Angels Camp, California; 700 cu. ft. air-compressor, Angels Camp, California; two 5-ft. 'Forwood Down' grinding pans, Nevada; Pacific stamp-stem guides, a number of orders to Mexico, four orders to Colorado, miscellaneous shipments to California mines; Cornish pumps, one 4-in. Neilsen pump, Dolly Varden mine; one 3-in. Neilsen pump, Nevada; two 8-in. Cornish station pumps with surface gearing, complete, Angels Quartz Mining Co.; Pacific rock drills, miscellaneous orders for California, including repeat order for three 3⅛-in. drills, Melones Mining Co.; Gates concentrators, one concentrating table, Plumas county, California; two concentrating tables and one slime table, Nevada.

TABLE OF CONTENTS

EDITORIAL

RUMORS that Nevada had a live volcano, prove incorrect. Peavine, like the late Mr. Jeffries, failed to 'come back'. The invigorating atmosphere at Reno seems to have its maximum effect in stimulating space writers.

CONSOLIDATION is the order of the day and it is now reported that the Ontario, Daly-Judge, and Daly West, at Park City, Utah, are to be brought together. The announcement is premature though negotiations are under way and English capital is interested.

CREDIT for designing the oil heater for compressed air, described in our issue of June 25, should have been given Mr. Charles Legrand, consulting mechanical engineer for Phelps, Dodge & Co. Inc. Mr. Gerald Sherman, superintendent of the mining department of the Copper Queen Consolidated Mining Company, informs us that in practice the expense of operation has been found to run above the estimates because of the difficulty in preventing distillation of the oil at the temperatures used.

NEW ZEALAND has been an interesting proving ground for many social and political experiments. In view of present proposals for change in the land policy of the United States, our readers will, we are sure, welcome the discussion by Mr. A. C. Veach of the New Zealand attitude toward mineral lands, presented on another page. The report from which this was taken was printed as an appendix to the hearings of the Congressional committee that investigated the Forest Service and Department of the Interior.

FOREST FIRES have been causing much damage this month. The principal loss has been in the Coeur d'Alene district in Idaho, where part of the town of Wallace and many outlying homes have been burned. So far the large mines have not been injured, though production has been checked owing to the general demoralization and the absence of the men who are fighting fire. Many a windlass and small prospecting outfit has been burned, and in the end the loss of timber will affect mining, the principal industry of the region. In adjacent parts of Montana and Washington fire is also raging. State and National troops have been called out to assist the officers of the Forest Service, and every effort is being made to control the fire. There has been some loss of life, but apparently this is not as large as at first feared. In southern Oregon and in Sierra, Placer, El Dorado, Trinity, and Siskiyou counties of California, fires are also burning and troops have

been sent from San Francisco. At Eureka the Hidden Treasure mine has been damaged, fire burning the timbers some distance down the air-shaft. Immense damage to the forests has already been done, but so far there has been little loss of life. It has been long since such serious fires have occurred, the patrol maintained by the Forest Service having detected the fires while still small and capable of being easily extinguished.

DEATH overtook the president of Chile, as he landed in Germany August 16. Don Pedro Montt was inaugurated September 18, 1906, and had yet a year to serve as Chief Magistrate. He was an able man and did much for his country. Among the important achievements of his administration may be noted the final settlement of boundary disputes with Argentine and Bolivia, the establishment of a trans-continental railway, the beginning of a line from Arica to La Paz, and a marked general expansion of industry. Chile has turned her energies from war to peace and is systematically and intelligently using the public credit to link her railways into one system, to develop hydro-electric power, to improve her harbors, and to build sanitary works. It is interesting to note that when Mr. Roosevelt started public interest in conservation in the United States, a corps of engineers was already at work in Chile re-estimating the reserve of nitrate; and while the American Congress refused to support a Conservation Commission, that of Chile created one to have charge of the nitrate industry and gave it large powers. A reclamation service has been proposed and will doubtless be established, and agrieulture as well as mining and transportation, has received the intelligent assistance of the Government. In all this work Don Pedro Montt had large part and the world as well as his country suffers from his death. Americans feel a peculiar interest from his recent visit to New York and our sympathy goes out to the people of our sister republic.

NOMINATION of Mr. Hiram W. Johnson as Republican candidate for Governor of California, backed up as it is by the seleetion of Mr. William Kent to run for Congress in the second district, and choice of others of the same faith for various positions, is much the most significant victory the 'Insurgents' have achieved. Indiana and Iowa were expected to rally to the new banner and did so. In Ohio there was the discontent but not the organization and the final result is uncertain. Not even, however, the theatrical campaign of Mr. Cannon in Kansas and his equally dramatic repudiation by the voters of the Sunflower State, is as significant as the California primary election. An unusually large proportion of voters has shown sufficient interest and alertness to go to the polls and vote, and the usual result has followed. Managers of a political machine expeet occasional defeats but count on the average result; always having their followers on hand at voting time. Waves of reform are characteristieally spasmodic. Aside from the special issues involved in the partieular elections of this year, the 'Insurgent' movement is not important if it mean either a mere temporary wave of enthusiasm or only the replacing of one set of leaders by another, and in time, let us say, the substitution of a six-cylinder for a four-cylinder machine. If, however, direct primaries and the aetivity of the Insurgents actually induce the average voter to take an intelligent interest in political affairs and to be persistent in expressing his opinion, the movement is one of the most profound and far reaehing that has occurred in American politics. It is still too early to dogmatize as to this. We can only express the hope that at least a step in the right direetion has been taken.

Cyanidation and Smelting

Cyanidation of concentrate involves many difficulties which are being overcome in many ingenious ways. In March, Mr. A. E. Drueker deseribed for our readers the methods used at Taracol in Korea, and in this issue Mr. F. C. Brown, recently manager for the Waihi Grand Junetion Gold Company, Ltd., contributes from experienee in New Zealand. Interest in the matter is world-wide and the practice is becoming increasingly common. It rests on solid economic ground. It is not only that by shipping bullion in place of concentrate the miner is independent of the smelter, and is paid for his gold at the rate of $20.67 per ounee in place of $19.50, but despite resulting waste of base metal, there is usually an actual economic gain. Smelters must base their charges not on the eost of handling a particular ton of ore, but upon the cost per ton for furnace mixture. Accordingly smelting rates are adjusted so as to best bring out steady shipments of silicious, lead, iron, and copper ores, in the proper proportion for economical handling in the furnace. As the processes of treatment and marketing require time, and steady running necessitates carrying large stocks of ore, interest charges on ore purchased naturally must be taken into account. It follows, without any necessary implication of unfairness on the part of smelter managers, that the rate on any particular ore may be high or low as compared with the actual cost of reducing it, and further that smelting rates on any given sort of ore only meet eorresponding rates for treatment by other proeesses when the smelter needs that ore to preserve the proper ratio in the furnaee. Since he must in any event melt much barren material, the cost of doing so has to be assessed against the ore that can best be spared. The basis of fixing an individual rate is therefore the same as in railway traffie—'the value of the serviee' or 'what the traffie will bear,' depending on the point of view. It is clearly to general advantage that the amount of barren material sent to the smelters should be as small as possible. If therefore a concentrate does not eontain sufficient lead or copper to pay the cost of reduction, it may or may not put a burden on other ores, according as its excess of silica or iron is desirable or the reverse. Sulphur is negligible since under present conditions the amount in lead and copper ores alone is greatly in excess of commereial requirements. Not only may a concentrate sueh as noted impose a burden upon other ores smelted with it, but its handling and transportation involves un-

profitable labor. The freight bill of every civilized country is enormous and it is good economics to ship in the most condensed form and that nearest the finished product, whenever possible.

These natural conditions have been complicated by others that are artificial and in any discussion of smelting rates the ratio of capitalization of the smelting companies to tonnage handled must be taken into account. It is frequently assumed that capitalization is properly measured by the cost of replacing useful plants. This is, however, by no means the whole measure of value. Large stocks and deferred sales require abundant liquid capital and the money spent in fruitless experiment is a proper charge on operating expense if the industry is to progress. These and other items properly enter into consideration of charges. Making all proper allowance, however, there seems little escape from the conclusion that the smelting companies have been over-capitalized and that in general too large a part of the profits of the industry has gone to the smelters rather than the miners. Mining involves more hazards than does smelting, and miners should therefore have the larger portion of the speculative profits. Since the security for return in smelting is greater, the rate of profit should be smaller. In America at the present time, this matter is complicated by the fact that practically all of the smelting companies have interests, direct or indirect, in mines, and it is not altogether easy to properly apportion the profits. In Colorado there was for many years an excess of silicious ores. The rate accordingly was made high on ores of that character and low on others. Naturally the first concern of the big smelting companies as they were organized was to assure a steady supply of the then less abundantly mined fluxing ores; which was done by purchase of mines. It was but human that the rates should be continued low on the fluxing ore and as much as possible of the cost of smelting assessed on dry ores. It was equally natural that production of lead and copper ores increased and that miners of silicious ore were driven to develop first chlorination and later cyanidation until the smelting rate on dry ore came to have no relation to the cost of treating the same ore by hydro-metallurgic processes. The obvious course would have been to change smelting rates so as to throw more of the cost on the fluxing ore; thus encouraging production of dry ore and discouraging production of the others. An alternative would have been to reduce rates as a whole. To do either, in any large way, would, however, have interfered with the profits of the enterprise as a whole, and naturally the managers preferred to try for other ways of meeting the situation. As a result the furnaces have been run at half capacity for some time in the hope of the discovery of additional silicious ores containing sufficient gold and silver to permit payment of a smelting charge. This was the natural and the conservative course, and there are good reasons for it aside from any selfish interest in immediate returns. Any arrangement that would permit unlimited production at Leadville and in other districts from which the fluxing ores come, would influence prices of the base metals, perhaps disastrously. Gold, however, is not subject to fluctuation in price and its output can be safely increased. Silver also remains valuable even though it is a commodity. Continued production of the gold and silver is profitable even though the world is not ready to absorb an indefinite amount of lead, zinc, and copper. The hydro-metallurgical processes have therefore flourished, and now, having been shown to be widely adapted to treatment of dry ores, are being applied to getting the gold and silver out of the complex sulphides that form the bulk of the concentrates. The fact that cyanidation, in particular, may be economically carried on in small plants is to its advantage, but fundamentally we believe that the present ascendancy of the hydro-metallurgical methods of treatment of gold and silver ores rests on the greater demand for gold and silver than for the base metals. A reduction in rates sufficient to allow the smelters to compete for the dry ore, even if possible, would result in an increased production of the base metals that would be disturbing if not disastrous.

Politics and Mining in the Far East.

Far Eastern politics is a deep mystery to most Americans. We are glad therefore to preesnt Mr. Jerome B. Landfield's letter on the political situation in the Far East in its relation to mining. We are especially pleased that he has put in a good word for the Siberian mines, in which we have great faith, and for the much abused and little understood Russian officials. It is true that railway development in Manchuria heretofore has been controlled by the problems of Russian and Japanese strategy. We maintain, however, that this should not be, and in the future is likely to become less and less true. If any strategy is to be taken into account China would seem to have first claim but better still railway building should depend on commercial needs. The lines should link countries together in friendship and business relations as do the American-Mexican railways, rather than be merely parts of rival war engines. Clearly this will be promoted by increasing the number of participating nations rather than the reverse. That the proposal to internationalize the Manchurian railways was not accepted does not discount its inherent soundness. In the long run commercial conditions are like to control and the recent railway convention between Russia and Japan seems to have been more nearly related to growth of bean shipments from Manchuria, and the necessity for through rates by Vladivostok, than to any war measure. The same was true of the opening of Port Arthur. Both were acts of ordinary railway strategy, moves of the traffic director burdened with freight, rather than deep laid schemes of war chiefs. Siberia, Korea, and Manchuria all have much to gain from a reasonable infusion of American miners and capital and just as Mr. Landfield has found by experience that the assumed difficulties in Russian territory disappear before tact and courtesy, so other friends assure us that they find the same true when dealing direct with the Japanese and Chinese in Korea and Manchuria.

The Black Hills of South Dakota—III

By William H. Storms

In 1876 the Father De Smet claim was located on the south side of Deadwood gulch, about three and a half miles above the town of Deadwood. A village quickly came into existence there, which was named Golden Gate, after a mine of that name, constituting one of the claims of the Father De Smet group. Numerous locations were made on the great outcrops of red-hued quartzose rocks which extended southeasterly over the hills from the south side of Deadwood gulch to Gold Run, a distance of nearly 8000 ft. On the north side of Deadwood gulch the schists continued with the huge included veins, or lenses of quartz, and the rocks were gold bearing, but they did not possess the peculiar characteristics of the veins to the southward, nor were they of equal value. Another early discovery was that made by the Manuel brothers, two French prospectors, who discovered gold-bearing rock on the north side of Gold Run, about a mile south of the Father De Smet mine. Like all of the other adventurers in the country, they had come in the hope of finding a rich mine, making a quick fortune, and returning to their home; accordingly they named their claim the Homestake. This was early in January, 1876. Other claims were quickly taken up on all sides of them, and the prospects were certainly most encouraging, as the ore all contained gold which could be easily detected by crushing the red rock and panning. The ore was low in grade it is true, very low in fact for a country situated 250 miles from the nearest railroad and in the heart of a hostile Indian country. To make the ore available, heavy machinery had to be brought in from the railroad at great risk and tremendous cost; still the miners were not without hope. The thing that puzzled them most was the unusual character of their ore deposits—immense masses of red rock, with more or less dirty white or red-stained quartz, in most cases without defined walls.

The hilltops were capped with porphyry, covering the ore with a tremendous overburden which, in all probability, would have to be removed. The amount of available water was limited, and what was the best thing to do under the circumstances, was a problem which, as far as they could see, the future must determine. As usual with the Western miner, a solution of the problem was not long in presenting itself. What these great deposits required to insure success was experience, courage, and money. These were soon supplied by capitalists, from the Lake Superior copper region and from California, who visited the mines or sent experienced mining men to make the necessary examinations. Among these latter there was a wide difference in opinion as to the availability of these ore deposits under the then existing conditions. Some condemned them without hesitation, as of no commercial value, others considered them a 'good gamble', and still others were confident that they could be worked with profit if properly equipped and handled on a scale commensurate with their magnitude. It was the men of this latter type who advised the purchase of the claims, and who afterward demonstrated the value of the deposits.

Among the men favorably impressed was Samuel McMasters, a Comstock miner. He had had experience with great orebodies before, and after carefully examining the claims of the Homestake group, unhesitatingly recommended his clients, Hearst, Haggin, and Tevis, to buy the property. This was accordingly done, and Mr. McMasters placed in charge. It was he and such men as A. J. Bowie, of the Father De Smet; Frank W. Allen, of the Caledonia; David Mason, of the Deadwood mine, and a few others, who did things in those strenuous early days, when the situation was without precedent in the annals of mining. There had been big mines opened in the vast desert of the Great Basin region, it is true—the Comstock, with its wonderful bonanzas; the big orebodies of the Eureka district, Nevada; and some others; but those ores were high grade, running from $20 to the ton up into the thousands. Here, on the contrary, were great ore deposits admitted to be worth nominally but $4 or $5 per ton, with a situation but little, if any better, than obtained in Nevada. They planned ahead and outlined the policy of the years of the immediate future. The distant years were yet far away. "Sufficient unto the day is the evil thereof," could well have been their maxim, in the years 1877 to 1885. Later, as conditions changed, methods changed with them: always for the better, always the mining was on an increasingly larger scale. It is true the early-day methods were not the best methods, not the practice of today, but they were good methods for their time and place.

The first mills in the Hills were built in Deadwood gulch, just below Central City, to work the ore from the conglomerate deposits. Soon mills were built to crush ore from the veins, and in less than two years from the date of the discovery of gold in Deadwood gulch, there were in operation in Deadwood, Blacktail, Bobtail, Poorman, and Gold Run, no less than 20 stamp-mills, containing from 10 to 35 stamps each. These mills all had light stamps—650 to 800 lb.—and all were run to their full capacity, night and day. Steam was the only power available and each mill was provided with a whistle, which at the different mills varied in tone with the amount of steam that could be employed to blow it or with the ideas of the owner. No mill was run on standard time, such a thing was unknown then in the Hills, and as the time varied from a few minutes to as much as three-quarters of an hour at the different mills, the effect of the blowing of these whistles was noticeable, particularly as the whistles were blown for all sorts of reasons, and apparently for no reason at all—as signals for ore, for time to go on shift and time to quit; time to eat and time to stop eating; for for the superintendents and for the foremen. Pandemonium seemed to reign in the gulches but, strange to say, if the mills, one and all, did not keep up their never-ending racket a man who had become used to it could not sleep.

Methods in the mills were crude and wasteful, but the 'cement' mines, as they were called, were rich, and so, too, were some of the veins, and the mines could stand the expense. Ore was hauled to the mills in wagons, sometimes during the spring, when the roads were a perfect slough, with the axles dragging through the mud. In summer the dust rose in suffocating clouds, and in winter there was often a glare of ice and the roads became extremely dangerous. Indeed, one cold morning, I saw a team of four fine horses carried over the grade by a heavily laden ore-wagon which had gotten beyond the control of the driver, the brakes being useless on the icy roadway. The entire outfit went down the hillside, 180 ft. into Deadwood gulch, killing one horse and so seriously injuring another that the unfortunate animal had to be shot. The other two were apparently uninjured, and the driver of the team saved his life by jumping.

Lead, S. D., General View Showing Homestake Mills.

Lead, S. D., Elison Hoist in Foreground, Water Resevoir on Hill.

Open-Cut, Homestake Mine.

On reaching the mills the ore was broken to proper size for the battery by means of hammers, there being no rock crushers in any of the mills at that time. All feeding was done by shovelers, and 'rule of thumb' was the common practice in milling the ore. All of the mill structures were of lumber except that of the Hidden Treasure, which was of brick. At Gayville, half a mile below Central, and near the present site of what is known as Cyanide Plant No. 2, of the Homestake company, was built a mill of unheard-of design. It was provided with a circular mortar, resembling somewhat the Ball stamps of the Lake Superior copper mills, but much smaller in size. It was equipped with wonderful cauldrons for 'cooking the ore,' and strange, shallow, saucer-like basins for the further treatment of the unfortunate pulp. This mill was built after the design of a spiritualist, but seemed to get no further than the constructive stage —the ore not being 'adapted to the process.'

The development of the quartz mines on the Homestake belt now progressed rapidly. Huge open cuts began to appear on the hillsides, at the Father De Smet, at Terraville, and on the Lead City side, in the Homestake, Palmetto, and other mines. Underground the great orebodies were being attacked vigorously and the square-set method of timbering was introduced with success, though eventually every large mine where this method of support was employed had disastrous caves, as the result of failure to fill the stopes with rock. First the Golden Terra at Terraville collapsed. At this mine a huge stope, as I remember it now, 150 ft. in length, 100 wide, and about 80 high, had been excavated in the great vein. As stoping had progressed the timbers had been placed after the most approved Nevada square-set method. The stope had been carried up well toward the surface and the dead weight on the timbers was tremendous—too much for them to sustain; consequently, notwithstanding every effort was made to check the subsidence by the placing of reinforced timbers and the building of cribs of solid timber, the ground continued to settle, a crack appeared on the surface marking clearly the area of subsidence, and toward the last the ground settled so rapidly that it was deemed impossible to save the stope. The men working below, some 30 in number, were ordered out of the mine, but too late for four of them, for the huge mass crashed down, even as they were leaving the stope. Two were thrown against the

walls of a drift by the concussion, and two were caught in the falling rock and timbers, the others, including the four who were imprisoned in the cave for several hours, escaped without injury. Later the Caledonia, the Highland, the Homestake, and the De Smet caved in much the same manner, differing only in detail, but all due to the same cause; that of relying too much upon the timber sets to hold the ground, instead of filling the stopes with waste rock as is now the practice.

The first large sale of consequence in the Hills was the transfer of the Father De Smet, Golden Gate, and Justice mines to a California company on December 29, 1877, for $400,000. By mid-summer, 1878, the Homestake company had acquired considerable property in Lead City, around the ground originally purchased from Manuel brothers, and had begun the construction of their first mill of 80 stamps. This was known as the Homestake mill and now contains 200 stamps. The Golden Star company soon thereafter built a mill of 120 stamps, to be followed by one on the Highland, with a similar number. Just over the hill at Terraville, the Golden Terra company, was developing a great mine, and the Deadwood company, adjoining it on the north was doing even better, and both were about to be equipped with large mills. Later these two mines were consolidated and their mills were joined. The De Smet company built a mill of 100 stamps in 1878. This mill was unlike any of the others in its arrangement, and I have never seen another similar to it elsewhere. The stamps were arranged in a double row of 50 stamps each, with the mortars facing and a central aisle between the two lines of amalgamating plates. The particular advantage of this unusual type of mill construction was the fact that it afforded greater bin capacity than the other type, where the batteries were placed back to back, and furthermore that it permitted an unobstructed view of the interior of the mill, which was considered an advantage. The Caledonia company, at Terraville, built a mill of 60 stamps in 1878, which was later increased to 80. Prior to this the Caledonia had a light mill of 20 stamps.

By the mid-summer of 1878 the placer mines in the vicinity of Deadwood had mostly been worked over at least once, and some of the ground, in the more shallow parts, twice and even as much as three times—Chinese usually making the final clean-up. Occasionally a rich spot that had been overlooked, was discovered and good pay was the result as long as it lasted, but such happy finds were generally short lived, owing to the small area that had been left. In a small way, placer mining was still carried on in some of the neighboring gulches, Two Bit and Pedee gulches being the most important of these, but nothing was ever found in any of them to create more than a passing interest.

Reference has heretofore been made to the occurrence of a bed of local conglomerate in the bed of Deadwood gulch. This calls to mind a story in connection with this cement bed. The owner of a placer claim on Deadwood about a mile above town had been one of the fortunate ones. That is, his claim had proved to be one of those that paid well, but the pay began to fall off and the owner feared he was about to run into a poor streak, whereupon he decided the proper thing to do was to sell, if he could induce any one to buy at a sufficiently high figure. The road between Deadwood and Central passed directly over his claim, and many vehicles passed daily, among them several hacks which were usually loaded with passengers. One afternoon a passing hack stopped opposite the working pit and an elderly man alighted. The claim owner was engaged at the moment in panning down the day's clean-up, to which, as he observed the approach of a prosperous-looking stranger, he did not hesitate to add with a liberal hand from his buckskin.

As the newcomer drew near, the miner said in his most cordial manner, "How d' do, stranger. You're just in time to see a fine bit of gold," at the same time giving the pan a dextrous twirl which exposed a handfull of dull golden grains and small nuggets.

"My gracious!" exclaimed the stranger, with surprised interest and admiration, "and that is gold."

"It sure is," responded the miner, "and just today's work, too, d' ye mind. Just look at it."

"And what do you estimate it to be worth?" inquired the tenderfoot.

"Oh," replied the miner in a careless tone, "there's a hundred and fifty, I should think, if it's a cent," and then added with convincing nod of the head, "You can bet this claim is one of the best of them."

"Well," responded the stranger, "that is fine—fine. I think mining must be a most interesting business, particularly when it is profitable, as it seems to be here."

"There, ye have just hit it exactly," exclaimed the miner, in admiration. "That is it exactly—when it is profitable, as 'tis here," and then added, sententiously, "I think a good deal of this claim."

"How many men do you work?" asked the stranger.

"Five, generally, besides myself," was the reply.

"And that gold then represents the work of six men for one day?" inquired the pilgrim.

"Call it five," was the ready response of the miner, "I don't do much myself. It's about $30 a day to the hand."

"I should call that very good," remarked the stranger.

"Good!" exclaimed the mine owner, "I'll gamble ye'll not see any better the length of the gulch this day."

"Would you sell out?" inquired the tenderfoot.

"Sell," said the miner with thoughtful intonation. "Sell," he repeated, "why, yes, I'd sell anything I got, provided I got my price."

"What do you ask for your mine?" now inquired the stranger, as he watched with much interest, the men down in the pit getting ready for the next day's work.

"Well," was the cautious reply, "I'd take $12,000 for it right now. It might get better, ye understand, and then I don't know as I'd be willing to let it go for that. In fact," he continued, "if it wasn't

for this rheumatism I have, I don't believe I would care to sell at all."

"Twelve thousand dollars," repeated the old gentleman, half to himself, while he continued to gaze earnestly into the mine workings where the sluices were mounted on trestles, and a China pump, driven by a water wheel, was slowly scraping the water out of a little basin in the bedrock.

"No hurry about it," said the miner. "I'll tell ye what to do. Come up again tomorrow morning, and run the mine a day for yourself and see how 'tis done. Ye'll understand it better then, and ye can see, too, what good money there is in it—twelve thousand dollars, it's dirt cheap."

The next morning the stranger was at the mine at an early hour, but not early enough to see the mine owner 'fix' the face of the working pit. The latter evidently felt that he could not afford to trust wholly to luck on that day of all others, so he added gen-

Highland Hoist, Homestake Mine.

erously to the prospective clean-up from his prolific buckskin. As a result of this forethought on his part, the clean-up that evening exceeded $250, and the stranger decided without further parley to take the mine at $12,000, and the two went down to Deadwood where the transfer was legally consummated.

Three days later the miner went up the gulch to visit the new owner of his mine and incidentally to remove some of his personal belongings from the cabin, and was surprised to notice that the stranger had discontinued mining where he, the former owner, had been working, and had removed the entire crew of men to the extreme lower end of the claim and was busily engaged in cutting a drain ditch down through gravel and cement to the bedrock beneath.

"What are ye doin'," he asked, as he surveyed the work from the bank. "Ye don't need a drain-ditch, man."

The tenderfoot explained that he had 'discovered' that the cement was not the true bedrock, that the former owner had been working on the cement, which, although it paid well, was a 'false bedrock' and that the pay was very much better on the 'true' bedrock underneath it, and that as a result of this fortunate 'discovery' he now had two pay-streaks instead of one. The former owner of the mine said very little, but thought much, and later remarked to intimate friends: "An' I took him for a tenderfoot. He's from Californey, and knew more about a mine in a minute than I ever will, and I'll bet he saw that false bedrock the minute he set foot on the ground."

Curves of Comfort

By Mark R. Lamb

With the thermometer standing at 120° the farmers of Imperial valley, California, work in the sun and are not uncomfortable. Le Neve Foster says, "In still saturated air at temperatures above 80 or 85°, it is hardly possible for men to do hard continuous work, even when stripped to the waist." ('Saturated air' is still a useful term, the Weather Bureau to the contrary notwithstanding. To the ordinary man it means air mixed with a maximum amount of water vapor.) In South Australia, in a shade temperature of 115°, men wear starched collars and work in offices without fans, while in Shanghai at a temperature of 95° life may be rendered hardly worth living even with cellular shirts and electric fans.

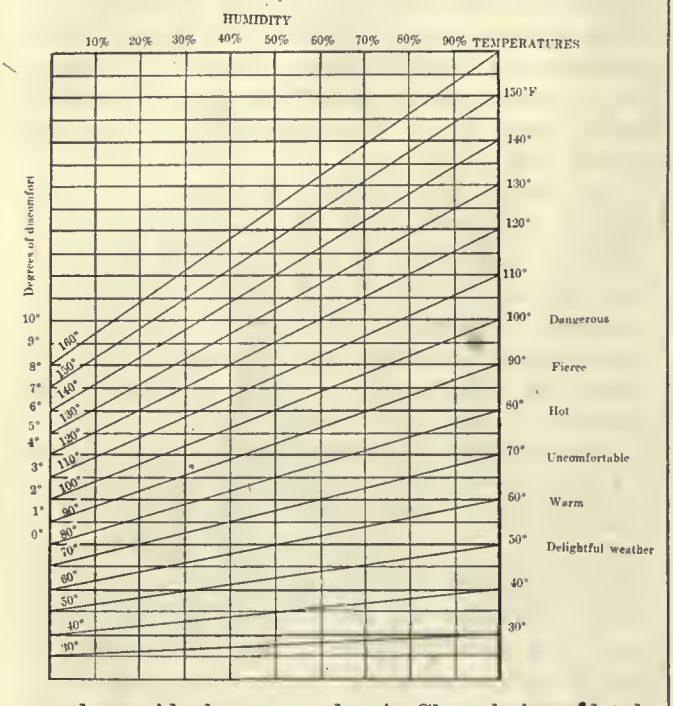
How climate may affect us certainly is not indicated on the thermometer, or on any other existing instrument. Periodically it is discovered that readings of temperatures alone do not convey a correct comparative impression of the bodily effects of air temperatures and water vapor quantities in combination. Besides these two factors, wind velocity also has an effect. For example, it is not sufficient to compare alone the temperatures and humidities of the breezy desert air and the dead air of a stope.

The New York *Times* suggested that the Weather Bureau give one figure including temperature, humidity, and wind velocity instead of each of these items separately, but the Weather Bureau replied that, "The problem is much more difficult than is here suggested. We have frequently explained that the sensation of temperature differs with every individual, and will vary with the same individual according to his physical and mental conditions. We think it must be left to each individual to predict his own sensations when once the Weather Bureau has predicted the temperature, moisture and pressure of air, and the wind velocity."

J. W. Osborne attempted to form a scale, but individuals differ so entirely in their sensations that "nothing satisfactory could be made out of a year's record of twenty observers." In 1872 he derived an arbitrary 'scale of sensations' expressed both by terms and by numbers, and he took account of wind as a most important climatic factor. Even with the three factors, however, the scale would not be perfect since the occupation of the observer is an important factor. For example, it is a well known fact that in Colón the coolest spot is at the end of the veranada toward the boarding-house, just where the suspicion of a breeze makes a little eddy. The majority of the workers on the Canal Zone cannot sit on that corner of the porch, however, so the tabulation should not be based on conditions there. Again, the sensation of the bare-headed shoveler in the sun differs from that of the pith-helmeted, pajamaed overseer who carries an umbrella. The above differences do not constitute a valid objection to the construction of a diagram which will indicate the feeling of the latter better than mere readings of

degrees Fahrenheit. This individual is usually imported while the former is entirely satisfied with the climate(knowing no other), and in any case is not interested in climatic comparisons. In fact, it may be stated as a general proposition that the out-door man has little time or inclination to criticise the climate—and also that he cannot choose his climate. Having thus scientifically eliminated the three factors of sun, wind, and labor the construction of our diagram is much simplified.

W. F. Tyler, of Shanghai, has tried to find out what function discomfort is of temperature and humidity. Taking zero as a condition such that when suitably dressed no personal discomfort is experi-



enced—an ideal summer day in Shanghai—and taking 10 as the maximum discomfort in the same city, then, within the range of his observations, the degree of discomfort is given by the expression d — 1.2 (d—w) — 66 where d and w are readings of the dry and wet bulbs respectively. As compared with the diagram accompanying this contribution, Mr. Tyler is willing to stand a higher temperature or humidity on a pleasant day, probably because his formula is based on observations taken out of doors, in moving air. My diagram has been prepared from observations begun in 1898, and taken at numerous places in North America, including such extremes of temperature and humidity as are observable in Death valley and in New York City. At the top are percentages of humidity; at the left is an arbitrary column of degrees of discomfort and at the right is a column of degrees Fahrenheit. The maximum bearable with saturated still air may be taken at 100°. In order to make clearer the gradation in the column of 'Degrees of Discomfort' I have added a scale of terms which require no explanation.

To compare conditions in two localities it is necessary either to know the relative humidities, or to obtain them from the differences between the readings of the wet and the dry bulb thermometer. The relative humidity is obtained by reference to the table prepared by the Weather Bureau.

For example, the temperature in Milwaukee today is 80° and the relative humidity is 55%, so that we are experiencing 3° of discomfort. At Yuma the temperature is 100° and the humidity is 12%, so that so far as bodily comfort is concerned the two places are the same.

It is not difficult to picture the big Swede at the Daggett borax works comparing his thermometers and finding the humidity 10% and the temperature 130 degrees!

"Mercy!" he says to the station agent. "Six of discomfort is enough for m-m-me! I wo- wo- wonder what it is in nu- nu New York."

"Pretty bad there," replies the agent. "Los Angeles tells me they are dying in the East. The temperature is only 90° but the relative humidity is 90 per cent."

The Swede runs his pencil a little way down the 90° diagonal to the 90% humidity line and across to—

"Well, l- l- look at that! Seven and a half of discomfort, and here we are only up to six! I'm glad I don't l- l- live in nu- nu- New York! That sure must be a hel- hel- healthy man's town!"

A FUSION METHOD

By George A. James

The following method may be of service to some of your readers. I have used it a number of years with uniform success: To economize time it is best to remove such bases as possible with acids as is the usual practice in other methods. The dried insoluble is mixed with two or three times its weight of sodium carbonate, and where unoxidized bases exist, sufficient potassium nitrate for their oxidation. The melt is made in a silver, platinum, or nickel crucible, according to the purpose of the analysis, as small portions of the crucible enter the fusion. Although this amount is minute it may have a bearing on the analysis, and should be remembered. The silver crucible is preferable in most cases. The melt is carefully heated over a Bunsen burner or alcohol lamp, until all moisture is driven off and the mass begins to cake. A piece of caustic potash, of weight equal to the substance, is placed in the crucible so that it may be made to touch the side, or a stick is pressed against the sides of the crucible until sufficient has melted and run down to bring the whole mass into fusion. This takes place almost immediately. The solution of the fusion is made as in other methods, taking the ordinary precautions for fluorides.

The advantages of the method are, its saving of time (but a few minutes are required), its not requiring a blast lamp or muffle, the smaller quantity of material to be evaporated, and the greater solubility of the melt. In the fusion of chrome iron the fusion may be greatly improved by a similar method. The chrome iron, mixed with sodium peroxide, is heated until it begins to show incipient fusion, when a small piece of potassium hydrate is added. It will be found that the effect is to bring the whole mass into immediate fusion. I have seldom found it necessary to re-fuse as is most generally the case when sodium peroxide is used alone.

Examination of Petroleum Properties

By Charles Janin

Geologic work, for the determination of oil territory, is generally combined with the making of careful topographic surveys.* In carrying on this work level lines are carried along roads, stream channels, and crests of ridges, and the elevation taken of all prominent outcrops that can be recognized as marking geologic horizons. This results in gathering a mass of accurate data for determining the intervals between important beds of rock and also the geologic structure or lay of the rocks. Level lines are also run to the mouths of any oil wells in the area, so as to determine the elevation of the oil sands and other beds of rock, whose positions are recorded on the logs of the wells. From these the intervals and degrees of parallelism that exist between the outcropping and sub-surface rocks can be established. By direct comparison the intervals between the different outcropping beds can be obtained. The structural relation of the surface and underground strata must be determined for each area examined, but a knowledge of the conditions existing in a number of different areas may show what can be expected elsewhere.

There are certain general geological conditions that should be known before undertaking the determination of the geologic structure of the oil-bearing sands from strata upon the surface, the first, and most important, being the possibility of an unconformity between the surface strata and the oil-bearing stratum. It is necessary to have a knowledge of all the factors governing accumulation in any attempt to define oil territory. These are, porosity of the reservoir rock, the geologic structure, and the degree of saturation by water. The first can be determined only by the drill; the second, under favorable conditions, by careful geologic work on the surface; the third by drilling a few test wells. Knowledge of the first and third factors is absolutely necessary for a correct interpretation of the surface structure shown by the map. For instance, in an area where two or more sands are productive, the map may show producing wells on the anticlines, along the steep slopes, and also in the bottoms of the synclines, the productive area not appearing in any way to conform to the structure; but, if the top of the water in each of the sands be determined, it will be seen that the sand yielding oil on top of the anticline, is not the one from which oil is taken in the trough of the syncline and furthermore is free from water. The sand in which oil occurs along the slope is, on the other hand, saturated with water up to a certain level immediately above which the oil occurs. Partial saturation is the condition most generally found, in which case accumulations of oil may occur anywhere with reference to the geologic structure. It is most likely, however, to occur upon terraces or levels as these places are favorable to accumulation in both dry and saturated rocks. Under all conditions the most probable locations for the accumulation of gas are on the crests of anticlines. Small folds along the side of a syncline may hold a supply of gas or the rocks may be so dense that gas cannot travel to the anticline but will remain in volume close to the oil.

It must be acknowledged that absolute determination of the occurrence of oil in any one locality by work on the surface, even where assisted by a study of the known underground conditions in developed territory is not possible. However, it is possible to calculate the degree of probability for finding oil from a careful study of indications and structural conditions. Drilling in new or unproductive territory is necessarily a most speculative venture. Any one of four results may be the outcome of the well where the sand is pierced. First, the sand rock may be found to be hard and close, incapable of holding oil or permitting the flow of any liquids through its mass. Second, the sand may be good but perfectly dry. Third, it may be good sand and be completely saturated with salt water, which may fill the well to a depth of several hundred feet, or, in some cases, even flow out upon the derrick floor. Fourth, oil may be found in such quantities and with such pressure that it will gush from the well at the rate of thousands of barrels a day, or there may be only a gradual seepage into the well amounting to but a barrel or two a day.

No fixed rule can be made for the selection of drilling sites in new territory, as much depends on the character of the strata. A new field should be tested by a series of wells at right angles to the strike of the beds so that beds of a different horizon are tested in each case. In no case should the non-success of a single well be considered conclusive evidence as there are few oil fields where there are not dry holes even in the midst of highly productive wells. In California conditions are exceptional in that so far no dry holes have been found in the midst of productive territory, except where the drilling has not been done properly. The reservoir sands here are so porous that any well tapping them, and properly seated and cased, yields some oil. Where there is an unbroken anticlinal fold with gently sloping sides, the best site is near the crest, but when the anticline has unequal slopes steeply inclined, the wells should be placed somewhat away from the crest on the less inclined side. Where the anticline exposes a broken crest and the oil-bearing series outcrops at the surface, or the rocks are merely covered by a local series lying unconformably upon the inclined petroliferous beds, the placing of wells is decided on the basis of the relative inclination and the position of oil-bearing rocks. If the dip exceeds 50° wells should be fixed to penetrate outcropping petroliferous beds at a depth of 800 to 1500 ft., but where the angle of dip is in the neighborhood of 20 to 30° a fair test can often be made by placing the well to strike the outcropping beds at 400 to 800 feet.

The presence of petroleum in the rocks of a district is not always indicated by any outward signs

*Details as to these methods will be found in the reports of the United States Geological Survey, such as Bulletin 318, and to 'Petroleum Mining,' by A. B. Thompson, to which readers are referred for further information. These reports have been freely used in preparing this paper.

that give the least elew to a casual observer. Many of the oil fields of the world owe their discovery to the accidental finding of oil in wells sunk for water or in the search for brine. Prospecting for the latter led to the discovery of oil in the United States. The physieal characteristics of petroleum-yielding regions vary widely in different countries. The prevalence of oil at times exerts a marked influence upon the topography of a district as a consequence of its injurious effect upon vegetation, but this latter is influeneed to a great extent by the frequency and amount of rain or the prevalence of long droughts. Where petroleum-bearing beds outcrop at the surface or are only covered by a superficial deposit of soil or alluvium, there is often a seepage of petroleum which, exposed to the action of the atmosphere, is converted into a more or less solid mass of asphalt. The character of the residue which accumulates depends upon local conditions and upon the quality of oil, as well as upon the topographical nature of the ground, for instanee, where the oil oozes from outcrops of the sides of hills, all traces may be removed by rains. Surfaee indications, that may be considered favorable for the presenee of oil, are mineral springs, natural gas, springs of petroleum, porous rocks saturated with bitumen, cracks in shale, and other openings in rocks filled or partly filled with bitumen. In the Santa Maria district of California, deposits of asphalt are associated with petroleum-bearing formulations occurring as veins, impregnations, and surface effusions. Frequently streams or pools of water have an iridescent coating of oil on the surfaee. Compounds of iron floating on water give a similar appearance and are often mistaken for oil. Which is present, can be determined by agitating the surface of the water with a circular motion. If the scum is iron it will break into irregular fragments; if oil, it will form bands of color. As a rule deposits of petroleum and bitumen occur in porous formations over-laid by impervious strata, such as shales or slates. In seareh for oil all outcrops of stratified rocks are of interest. There are generally better exposures of these rocks along the sides of streams, in canyons, and in gulehes. If any brown or black material is seen in the seams of the rocks or porous strata, tests should be made for bitumen, using such solvents as bisulphide of carbon, chloroform, or turpentine which usually give a blaek or dark brown solution if bitumen is present.

In the examination of properties already producing, it is necessary, besides going into geological, geographieal, and topographieal details, to obtain aeeurate information on the following points: Number of wells and their condition, whether productive, exhausted, or dry. Log of eaeh well, if obtainable, giving the depth and thickness of each distinct formation penetrated, with lithologic character and place of beds yielding oil, gas, tar, or water. The record should also give the production of each well compared to what the well produced when first opened, it being partieularly important to notice whether there has been a gradual or sudden falling off in the flow. The variation of pressure compared to the variation in other wells in the vicinity, and the distanee to wells compared should also be noted as these indicate open communication between wells or otherwise. An analysis of the oil should be made compared with oil produced from wells in the same distriet. The presence and quantity of water, fresh or salt, also of water in the nearby wells is of importanee, as the penetration of water strata by nearby wells may flood the oil strata and cause serious trouble. Some of the most promising new oil fields have been suddenly and completely flooded by water and the area had to be abandoned. There has been legislation in several States to proteet producers from negligent, short-sighted, or criminally careless methods which might result in destroying or damaging valuable wells. Notes should be made of the cost of each well and of any special difficulties in drilling; the kind of pump and power used, cost per barrel of oil raised: the storage facilities, whether tanks or reservoirs, and capacity; the separation of oil from water and sludges; and any special features that have been brought to light by development.

In most oil fields the oil is raised mixed with salt water, and often the oil from flowing wells is intimately mingled with a large proportion of salt water. The great Mexiean gusher whieh in 1908 yielded some 400,000 tons of oil in two months, eventually produeed chiefly salt water at a temperature of 160°, the flow being estimated at from 35,000,000 to 50,000,000 gallons daily. In the Russian oil fields fresh water is so scarce that the main sourees for drinking are obtained from evaporators.

Titles and the legal status of any existing lease of contract are matters that should be carefully investigated. The disposition of the product and the price should be determined since the commercial handling and marketing of oil is one of the most important factors in oil production. Usually sale is arranged by contract with one of the large purchasing agencies. A normal priee to the producer in California at the well, would now be in the neighborhood of 25 to 30e. per barrel for fuel oil. Most of the larger corporations purchasing oil land, now figure on oil at the well at 25c. Any considerable rise in price could only be due to a deficiency in the supply, whieh is extremely improbable, or to a decided increase in demand. The recent high priees have been the eause of great activity in wild-eatting and in the development of new wells. This obviously greatly increased the production and could not but react against the price because of overtaxing the marketing facilities.

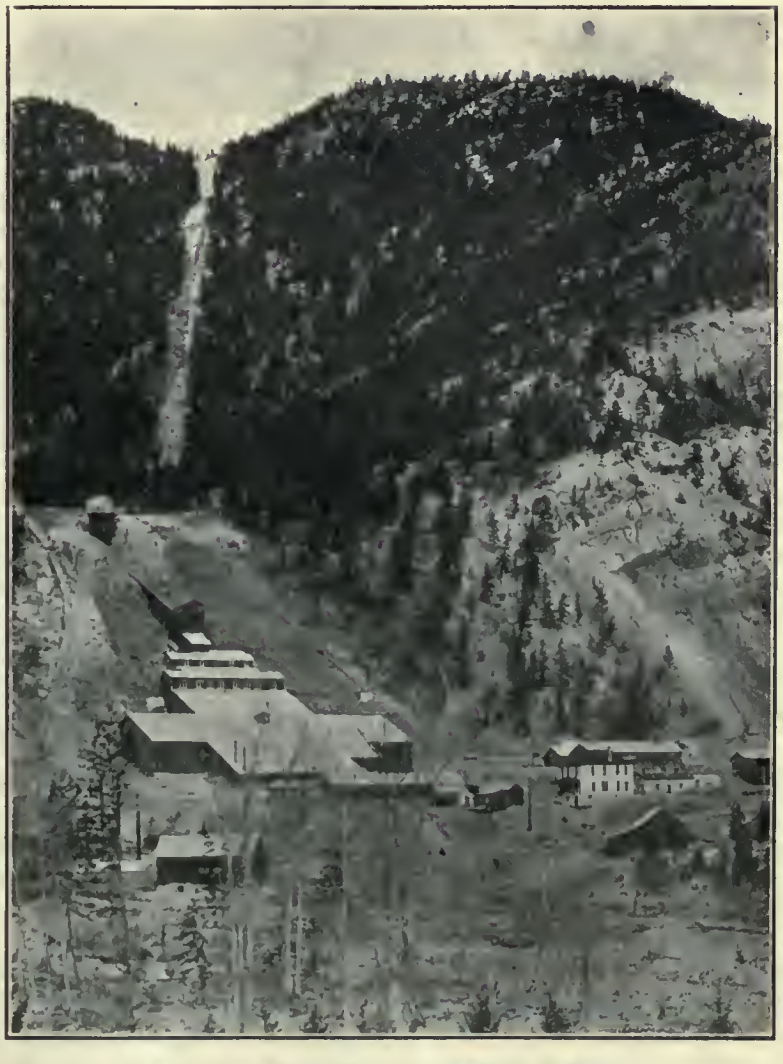
In Alaska much of the land is covered by a layer of moss. It has been the practice to plow the moss under. In the cold soils the moss is slow in rotting, and there appears to be a tendeney for a greater acidity to develop. It has been found that a better plan is to tear up the moss by light plowing, followed by harrowing, and after it has become dry to burn it. By this method uniform stands and good crops have been obtained the first season, whereas several years are generally required for equal results if the moss is plowed under.

The Nickel Plate Mine and Mill

STAFF CORRESPONDENCE

Among the gold mines of Canada the Nickel Plate is one of the most successful. It belongs to and is operated by the Hedley Gold Mining Co., and is situated on Nickel Plate mountain, in the Osoyoos division of the Yale mining district, British Columbia. The company's mill, power-house, and office buildings are at Hedley, situated on the Similkameen river; the mine is 3½ miles east of Hedley, and nearly 4000 ft. higher. The Great Northern Railway Co. is extending its line from Oroville, Washington, to Vancouver, B. C., and affords train service up the Similkameen valley through Nighthawk, Keremeos, Hedley, and Princeton, the last-named being the present terminus. The Similkameen, just large enough to be called a river, heads in the Hope mountains and flows into the Okanogan, at Oroville. The valley is narrow, but has a productive soil, as is evidenced by the fields of hay and grain, and the orchards. A number of smaller streams flow into the Similkameen through side-canyons; among these is Twentymile creek, the waters of which are brought through a flume and pipe-line to the Hedley company's plant to drive Pelton water wheels. The Hedley Gold Mining Co. owns 24 Crown-granted mining claims, the principal development being on three of them. The mine was opened in 1899 by the late Marcus Daly, and it was operated by him, and after his death by representatives of his estate, till August 13, 1909, when it passed to the control of this company by purchase. I. L. Merrill, well known at Bisbee, and elsewhere, is president of the company, with C. D. Fraser as secretary and treasurer, and G. P. Jones as general superintendent. The Daly Reduction Co., whose stock is controlled by the Hedley Gold Mining Co., operates the mill, W. D. Thornton being at the head of the subsidiary company. The greater part of the mine development, the construction of the mill and tramway, were accomplished under the management of M. K. Rodgers. He was succeeded by R. B. Lamb, and the latter by F. A. Ross. Mr. Ross was the last one of the managers under the Daly ownership. G. P. Jones, now general superintendent, has been connected with the property for the last ten years as mine superintendent. The credit for opening and developing the mine under difficult conditions, and the installation of excellent equipment, undoubtedly belongs to Mr. Rodgers and Mr. Jones. During the first few years of development machinery and supplies were sent in to Nickel Plate mountain from Penticton, 45 miles away, on Lake Okanogan. After the Great Northern had completed its railroad to Oroville, freight was hauled from that place up the Similkameen valley. Three years ago the railroad was finished to Keremeos, and only within the last year has train service been established to Hedley and Princeton.

The orebody, consisting of a gold-bearing silicate of lime, has a thickness of 10 to 80 ft., has a dip approximately 23°, between a hanging wall and foot-wall of andesite. The gangue, made up of epidote, garnet, and calcite, contains gold in free state and also in association with arseno-pyrite. While some high-grade ore has been mined and milled, the general average is now about $12 per ton. The mine was developed and is being operated through a series of adits driven from the side of the mountain. There are nine of these, and ore is being hauled out through five. The plan followed has been to drive these adits into the foot-wall to the orebody, then to sink inclines on the ore, which is hauled in mine cars to the top of the inclines by air-hoists. The pillar and chamber system is employed, and no timber is used. No. 3 adit reaches the orebody at a distance of 700 ft. from the portal; No. 4 adit, 150 ft. vertically below No. 3, cuts the orebody 1300 ft. from the entrance. While there are three other ore-shipping



Nickel Plate Mine of Hedley Gold Mining Company.

adits, No. 3 and No. 4 are the ones from which the greater tonnage is shipped. The ore is hauled in 2-ton cars from the farther ends of the principal adits by electric locomotives to the surface, where the trackage connects with a 9000-ft. electric line, over which the ore is hauled in 12-car trains down a 5-ft. grade to the transfer bins at the head of a 10,000-ft. gravity tramway. This tramway, which is operated in two sections, has three rails, with a fourth rail at the passing stations. This trackage from the upper terminal to the mill-bins makes a descent of 3900 ft. The ore is hauled over this tramway in 5-ton skips, the up-bound and down-going skips traveling in balance, always subject to the controlling machinery at the head of each section. At the centre station, where the two sections connect, the skip is merely attached to the cable that operates on the section over which that skip is destined, and detached from the cable that serves the section over which it has just passed. Some parts of the tramway trackage have an incline of apparently 40°. Compressed air, for the drills and hoists at the mine, is conveyed from the power-house at Hedley through a 6-in. pipe, 17,000 ft. long; and the electric power for the ore-haulage and other purposes at the mine is generated at the same power-house, transmitted to the lower terminal of the electric line, where it is transformed from an alternating to a direct current by a Westinghouse motor-generator for the electric-haulage system.

The ore passes from the lower tramway tipple to two jaw-crushers by which it is reduced to 1½-in. size, and is conveyed thence to the mill-bins, having the capacity of 1600 tons. The crushed ore passes automatically to the four 10-stamp batteries made up of 1050-lb. stamps. Formerly each stamp dropped 6 in. and 106 per min. Within the last three months such changes were made as to give the stamp a 7¼-in. drop and 99 per min. The result is said to have been an increase in the crushing capacity of 600 tons per month for the 40 stamps, without making any change in the screens which are 20-mesh. Certain installations of new equipment in the mill are being made without interrupting the regular operations. When the new equipment is ready the batteries will crush to only 16-mesh, the pulp will be classified by 8 Bunker Hill screens, the coarse product to be concentrated over 8 corrugated belt vanners; the vanner tailing will be pulverized to 100-mesh in a 100-ton Gates tube-mill, having Montana-Tonopah lining. The tube-mill product will unite with the fine from the Bunker Hill screens (which runs less than 60-mesh), and after being reground will pass to classifiers and hydraulic sizers; the coarse from the latter is to be concentrated on 16 smooth-belt vanners, the fine from the sizers passing to 10 Deister tables. The middling from these tables is to be reconcentrated over two other similar tables. The tailing from the smooth-belt machines will pass to the sand vats; the tailing from the Deister tables to the slime vats. This shows the method of separating the sand from the slime. No part of the sand will reach the leaching vats coarser than 60-mesh. The cyanide plant, as formerly constituted, provided for leaching the sand 12 days in the upper vats and 14 in the lower; but when the new methods shall be in use, by the time this is in print, there will be only the single treatment of the sand, and the proportion of sand will be but 25% of the whole. The plan is to collect the slime in four 200-ton settlers, from which is is to be pumped into six 200-ton agitating tanks, wherein mechanical agitators are to be used. The gold solution is to be decanted from the agitating tanks and treated by two Merrill precipitation presses, in which zinc dust is used. The slime residue in the agitating tanks—that remaining after decantation—will pass to two Oliver filter-presses, the solution to pass to the precipitation presses and the caked slime into the river. There is no crushing in cyanide solution, the first cyanide being introduced into the sand vats and into the agitating tanks. Under old arrangement and methods from 15 to 20% of the total saving has been made on the amalgamating plates, 55% by concentration, and the balance by cyanidation. Since January 1, 1910, the total extraction reached 93%. Discarding the amalgamating plates is being considered, though this may not be done. The concentrate product, the base of which is arseno-pyrite, amounts to 200 tons per month and runs high in gold. By coarse-crushing in the stamp batteries, followed by regrinding, it is estimated that the capacity of the mill can be increased from 160 to 200 tons per day. The consumption of cyanide per ton of sand and slime treated amounts to ½ lb., and costs 10c. per ton. The cost of mining and milling, as shown by the last three months operating, was a little less than $5 per ton of ore treated. Recent experiments led to the modifications now being made. Roscoe Wheeler is the company's metallurgist, with C. W. Merrill consulting. The present force of 140 men is larger than usual, due to the construction work. Ordinarily the force amounts to 75 men. The report for the quarter ended June 30, showed a net profit of $99,154, equal to three times present dividend requirements. The dividend rate is 3% quarterly.

The power-plant is hydro-electric, with steam auxiliary equipment. The flume by which water is diverted from Twentymile creek and delivered at the power-plant, is 13,000 ft. long, coming through the penstock at a pressure of 187 lb. per sq. in. The electric machinery consists of a 100-kw. A. C. Westinghouse generator, direct-connected to a Cassel water-motor; there is being installed a 360-kw. Westinghouse A. C. generator, direct-connected at one end to a 400-hp. Goldie & McCulloch Corliss condensing steam engine, and connected at the opposite end of the shaft to a 400-hp. Doble water-wheel, thus permitting the plant to be operated by steam or water-power, or both. The plant contains six return tubular boilers, aggregating 325 hp. The air-compressor, a cross-compound, 2-stage machine, is direct-connected to, and driven by, an 18-ft. Pelton wheel. Formerly the mill machinery was operated by water-power direct, but now electric motors are being installed throughout the mill to supplant the water-power, the water motors are being retained, however, as auxiliaries.

Cyanidation of Concentrate

By F. C. Brown

Probably most ores will come under the class of ores containing gold and silver finely disseminated through the various mineral constituents, as there are but few cases where all the valuable metal is in the form of free gold and silver, or where the gold and silver is in such forms as to be easily dissolved by cyanide solution. The ores and cases to which I especially wish to direct attention are those where the metals, other than gold and silver, if recovered in the form of concentrate, are not of sufficient value to cover shipping and treatment rates on the concentrate. In these cases, and there are no doubt many of them, it is advisable, if possible, to treat the concentrate at the mine for the recovery of the gold and silver, and allow the lead, zinc, copper, and other metals, to go into the tailing.

For the last three years I have been at a mine in New Zealand where just such conditions were present. The ore consists of a gangue of quartz and calcite containing the following minerals finely disseminated through it: iron pyrite, zincblende (chiefly the black variety), galena, some copper pyrite, and traces of arsenic, antimony, and selenium. By analysis it was estimated that 8 to 10% of the total weight of the ore consisted of these minerals. The gold and silver value of the ore was about $9 per ton (of 2000 lb.), about $1.50 of this being silver. There are no smelting concerns in New Zealand. Any concentrate produced has to be sent at heavy expense to Australia, and it was found that although 40% of the total value of the gold and silver content of the ore could be recovered in the form of concentrate there was little profit from the sale of the concentrate after paying bagging, carting, shipping, and treatment charges.

Upon taking over the management of the mine I at once made arrangements for treating the concentrate at the mine, and a special cyanide plant was erected for this purpose. The results were highly satisfactory as it was found that a 90% recovery was effected at a fairly reasonable cost.

The concentrate treatment consisted of the following steps: (1) regrinding in tube-mill; (2) agitation by compressed air in Brown (Pachuca) tanks with fairly dilute cyanide solution; (3) vacuum filtration. Great difficulty was experienced in grinding the concentrate sufficiently fine. Some idea of the fineness necessary may be obtained from the fact that, before regrinding, all the concentrate would pass 200-mesh sieve and it was estimated by time settlement-tests made in water, that the reground material would all pass 400-mesh if such a sieve were obtainable.

A fairly large tube-mill was required for about 10 tons of concentrate per day (24 hr.), so it can readily be seen that the power consumption per ton was high, as was also the wear of pebbles and liners. After running the plant some months I came to the conclusion that such fine material by itself is too fine for economical grinding in tube-mills, and this opinion was strengthened by the fact that later, although very much finer grinding of the ore was tried and consequently finer concentrate produced, the percentage of extraction after regrinding was lower than when the ore was being crushed coarser. From this I inferred that the concentrate was not being reground as fine as before.

In order to overcome this difficulty it was decided to try adding coarse sand to the concentrate as it entered the tube-mill, the idea being that this gritty material would help the grinding, in the same manner that the barn-yard fowl picks up grit to grind its food. The result of this experiment was even beyond our anticipations, as it was found that the extraction was increased some 3 or 4% and the wear on liners and pebbles was materially reduced. It next occured to me that the concentrate might advantageously be reground in the tube-mills used for grinding the ore, provided some simple method could be devised for continuously feeding it to these mills, there being always a good supply of coarse gritty material in these mills to assist the grinding. After numerous experiments such a method was devised and the success of the scheme was all that could be desired. This meant the abandonment of the special concentrate-treatment plant. The total extraction on the ore was higher than when the concentrate was treated separately. It is now about 90%, and the costs for labor and chemicals are considerably lower. This method of treating the ore and concentrate together has already been briefly described (the result of a communication from me), in an article by A. Grothe, president of the Mexican Institute of Mining & Metallurgy, which was published in the proceeding of the Institute for August, 1909, 'Cianuración de Concentrados,' but this further reference to the method will be of interest to some. I have come to the conclusion since arriving in this country, that there are many mines in the Rocky Mountain regions situated away from the railroads, which, if they had a plant at the mine that would give a high extraction of the gold and silver content of the ore in the portable form of bullion bars, would give the owners materially increased profits compared with the present system of shipping the concentrate. This method of treatment might also bring about the resumption of work on some mines and the opening up of others.

COST OF MINING

In an article descriptive of Radersburg, Montana, which appeared in this paper August 6, the statement was made that the cost of mining was $15 per ton. This figure applied particularly to the Black Friday mine, and contemplated total cost of mining, transportation, smelter charges, and all other expenses, and it is believed that this will be materially reduced within a short time by improved methods. The general cost, at present, of mining, transportation, and reduction of the ores of the camp is about $8 per ton. As soon as arrangements have been completed to treat the ore at the mines this cost will be reduced several dollars per ton in saving of transportation charges alone.

New Zealand and American Mining Law—A Contrast

By A. C. Veach

*The United States in dealing with its national domain early endeavored to separate mineral from non-mineral lands. At first this was accomplished by the automatic means of reserving in all grants and patents the minerals which were then considered of importance. Under this practice it was impossible for any deposit of gold, silver, copper, or lead, to be wholly alienated. This plan was soon abandoned for one in which the separation rested entirely with the officials. They had the power to absolutely reserve from sale under the ordinary land laws any lands which were known or supposed to contain minerals and to lease the same, but such reserved mineral lands could be sold only by special act of Congress. If land was not specifically reserved in this way it could be acquired under the ordinary land laws and the grants or patent in such cases contained no reservations. This plan was practically abandoned in the forties and there developed the present more drastic one which absolutely prohibits the sale of any mineral lands except under specific acts. These mineral laws provide for the sale of mineral lands under certain special conditions and at a higher price than that charged for non-mineral lands. No provision was made for leasing or for the insertion of mineral reservations in grants. In the administration of the laws in this third period the Government officials no longer took the initiative of making definite mineral-land reserves analogous to the lead and copper reserves of the preceding period. The policy of the land office during this third period was essentially a passive one. In the beginning of the period the difficulty of determining by field examination and classification what were and what were not mineral lands resulted in the initiation of a plan which endeavored to throw on the purchaser the responsibility of making this determination, and which has persisted more or less unchanged to this day. Under this plan the land office has required the agricultural claimant to assert under oath that the land was not mineral land and that he was acquiring it not for its mineral value, but only for the purposes of settlement and cultivation. Until recently the land office as a general rule has accepted such a declaration as entirely conclusive, and the administration, decisions, and rulings of the land office during the earlier period did much to make this declaration a mere form and to afford plausible excuses to persons desiring such conscience salves. As a result large areas containing valuable minerals are claimed at present under agricultural patents.

In this plan of shifting the responsibility from the land office to the purchaser, and in the fact that a higher price was charged for mineral than non-mineral land is found a most hopeful possibility of remedial action, a possibility of recovering to the Nation all mineral values except those disposed of under the mineral-land laws. If Congress should enact at this time that in every case, both in the past and future, where the purchaser of land from the Government made a non-mineral affidavit, that all minerals belong to the Government, it would leave each man with exactly what he swore he was getting and exactly what he paid for. Such an act would be eminently just. In individual cases it would be less severe that the attempt that is now being made in the Western States to recover to the Government by lawsuits mineral lands acquired under agricultural-land laws. In these cases the Government seeks not to take from the patentee everything; it asserts that the patentee has been a perjurer and has defrauded the Government. Under the plan here suggested all such points of difference and all such charges vanish. The oath is regarded not as perjured statement, but as an honest indication of intent and desire. The claimant's statement that he was acquiring the land only for agricultural purposes is made binding on him. The charge of fraud likewise falls; the Government has under this solution not been defrauded; it has sold the agricultural values and received the usual price therefor. The patentee retains what he bought; the Government what it did not sell. This is a solution of the matter of Western 'mineral-land frauds,' which can but appeal to all men as entirely fair. On the point of legality of such enactment the question, if any, to be decided is not, Would a court of law sustain such a contention if made under existing practice and ruling without specific enactment? but Has Congress the power to pass a law which but confirms to the Government the ownership of certain things which it has never sold and which at the same time leaves to every patentee from the Government exactly what he swore he was getting and exactly what he paid for; no less, no more? Eminent lawyers have stated that they believe the Supreme Court would look at the matter broadly and hold such an act constitutional.

New Zealand from almost the very beginning has shown a like desire to separate mineral from non-mineral lands; its laws have always authorized the sale of known mineral lands and do today; there has been no general enforcement of the common law right of the Government to the precious minerals. They are today, as in the United States, controlled by the owner of the freehold. There are no 'mining on private property' acts, and while some lands are under certain conditions subject to resumption without payment for gold or silver values, it may be said that for most purposes deeds, as in the United States, are now held to convey all minerals. In some respects the New Zealand laws may be regarded as more liberal than those of the United States. New Zealand has never declared that "in all cases land valuable for minerals shall be reserved from sale except as otherwise expressly directed by law." The land department has never required of any purchaser a declaration that he is not acquiring the land for its mineral value, and thus by his own declaration practically estopping him in equity, though not

*Abstract from 'Reports on Mining Laws of Australia and New Zealand'. Government Printer, Washington, 1910.

in present practice, from claiming the mineral values which may be in the lands purchased. The New Zealand land laws have, however, incorporated several discretionary features not found in the American laws; they have empowered their officials to grant mining leases; to make reserves for public purposes; to refuse to sell any land, and to fix the sale price of all lands. These discretionary features have made possible a degree of efficient and intelligent business administration which is surprising to an American.

The result is that while the United States has disposed of its mineral lands without let or hindrance, New Zealand has disposed of practically no mineral lands as such. A search through the old government and provincial gazettes during the early period when the provisions for sale were most explicit, and when notifications of such sales were required in the gazettes, failed to reveal a single notice of this kind. The mines department reports that no known mineral lands have ever been sold by the Government. Among mining men not one knew of the Government sale of a single piece of land as mineral land, and several stated quite positively that such a sale would not only not be tolerated but would be illegal, which certainly indicates that the custom of not selling mineral lands has been followed so consistently that it has generally come to have the force of law. Some lands containing minerals have been sold, but the freehold lands that are now known to contain commercial minerals are restricted almost wholly to areas containing lignite or brown coal, which were disposed of very early in the history of the colony. It is estimated that in 1906 the coal derived from private property in New Zealand did not exceed 30% of the total tonnage, and represented a much smaller percentage of the total value. The value of all minerals, including coal, derived from freehold land did not in that year exceed 10% of the total; indeed, Charles Rhodes, secretary of the Waihi gold mine, and one of the leading mining men of New Zealand, estimates the amount as less.

The net result of the administration of the minerals contained in the public domain of the United States and New Zealand for the past sixty years is that, while both have provided for the sale of mineral lands and neither has reserved minerals in patents or grants, in the United States all the mineral production is either derived from freehold land or land that is in process of becoming freehold, while in New Zealand 90% of the whole mineral production comes from areas held under lease from the Government. Truly, this result but corroborates the statement called forth by the investigation in Tasmania that the patriotic and efficient administration of the land affairs of a country is not a human impossibility. The country in which these results have been attained is one of no mean mineral wealth and is one in which the mining industry is in a very healthy and progressive condition. It contains, in the Waihi gold mine, the most productive gold mine in Australasia and the third or fourth in the world. It has the third most productive colliery company in Australasia and is second only to New South Wales in its total coal production. It has been the centre of several gold rushes, which, following those in California and Victoria, to some degree depopulated the Victorian fields and attracted many from California. It has produced in a little over fifty years more than $350,000,000 worth of gold, and, with but little over one-sixth the area of Alaska, produced in 1905 three-fourths as much gold, five times as much silver, and many times as much coal. It has one-third more area and about three times the population of Utah, and in 1905 produced one-quarter more coal, about twice the amount of gold, and one-eleventh the quantity of silver.

JOHNNIE MINING & MILLING COMPANY

The property of the Johnnie Mining & Milling Co. embraces 19 claims and various water rights in Nye county, Nevada, about 14 miles from Amargosa. Development consists of an 850-ft. working shaft and nearly two miles of underground workings. The orebodies are found on a limestone-quartzite contact, the vein striking northeasterly and dipping 45° to a depth of 450 ft. Below that the dip varies between 18 and 30° until the 700-ft. level is reached, where the vein becomes steeper. The gold ore is found in shoots and chimneys that have been found to increase in size and tenor of ore to the present depth attained. The vein is from 4 to 20 ft. wide, averaging 10 ft., and the ore contains from $6 to $10 per ton. The shaft, which is 854 ft. deep, will be sunk to the 1000-ft. level. The 100 ft. between the seventh and eighth levels was sunk in 35 days, and the 900-ft. mark will probably be reached by September 10. Cross-cutting for the vein is now progressing on the 800-ft. level, and at the present rate, 4½ ft. per day, the orebody should be reached before the end of August. On the 700-ft. level the vein showed a width of 22 ft. and the dip of the wall there indicated that the width at 800 ft. will be between 25 and 30 ft. From 65 to 70 tons of ore per day are being treated in the mill. This consists of 16 Nissen stamps and one slow-speed Chilean mill. It is planned to increase the mill capacity to 200 tons per day. There will also be installed at the mine a hoisting plant of 200 tons per day capacity. It has not yet been decided what kind of power will be used. The Tecopa Water Co. has promised water-power by the last of November and this will be utilized if it is ready. If too long a delay is probable the plant will be designed to use oil fuel. The company has leased its Fraction claim to a syndicate called the Fraction Leasing Co. Work has already been started and it is expected that a 22-hp. hoist will be installed by September 1. This claim is developed by a shaft 170 ft. deep and about 250 ft. of driving on two levels. The contract with the leasing company provides for the sinking of the shaft to the 400-ft. level. In the meantime workings from the Johnnie will be extended and eventually connected with this shaft, thus providing an air-shaft and another means of egress from the main workings. Arrangements are being made to lease the Minnie May claim and it is expected that work will be started before long.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Gold Mining in the South

The Editor:

Sir—It is rare now-a-days to hear anyone speaking seriously of gold mining in the Southern Appalachians. I have noted your editorial on the subject in the issue of July 23 last and was much interested in the attempt being made by the Columbia Mining Co. to arouse interest in gold mining by offering advantages to prospectors which they have not previously enjoyed. The experiment will be worth while and the outcome awaited with interest. I spent some years professionally in that region and know it, together with a good many of its advantages and disadvantages. I am, therefore, much interested in anything that promises to put mining there on a solid basis. In 1904 I was called upon to investigate conditions at one of the then most promising mines in that part of the country. I found a state of affairs which could hardly have been worse. Every piece of equipment on the property had been bought second hand, and none of it was in condition to give good results, most of it being unsuited in design to the work required of it. The vein consisted of 4 or 5 ft. of talcose quartz schist, assaying from $12 to $20 per ton. The gold was extremely fine and only about 60% of it could be saved on the amalgamation plates, and the valuable tailing was run to waste in such a way that there was no possibility of ever recovering it. No records of any kind were kept, even the assay value of the ore being unknown. All the facts I had to have to make an intelligent investigation, I was obliged to dig out myself by a long series of samplings and experiments.

Hoisting was accomplished by bucket without any kind of guides in the shaft. The ore broken in the faces was wheeled to the shaft in wheelbarrows, dumped on the floor, shoveled into the buckets, and hoisted. At the surface the bucket was dumped on a platform, shoveled into a wheelbarrow, wheeled about 100 yd. to the mill, dumped on the floor, where it was broken by hand hammers, and then fed by hand into the mortars of a light 20-stamp mill. I have seen better mills than this one on the junk heap.

It would take too much space to detail the condition and methods obtaining, but the above is a fair sample. I made many reforms and built a small plant to cyanide the tailing, which gave excellent results as long as I remained. When I left, the management went back into the old hands and a policy of reversion began again. Everything was changed as much as possible, even the stamp feeders being thrown out and feeding by hand resumed. In my opinion it is this sort of thing that has killed Southern gold mining. The people have no experience to guide them and they will not follow the counsels of those who ought to know. The man with the divining rod gets a much better welcome than the legitimate engineer. The mine of which I have been speaking should have yielded a handsome profit, but as a matter of fact no one made anything out of it, and it was finally sold for its debts. There are a number of good deposits of gold in the Southern Appalachian region, low grade generally it is true, but some of them extensive, and with proper management they could be made profitable. The metallurgy is usually not difficult, the great need is simply good business management and efficient technical direction.

H. A. MEGRAW.

San Louis de la Paz, Mexico, August 8.

A Cyanide Problem

The Editor:

Sir—In your issue of August 13, I note a communication signed 'Mine Owner, Tucson, Arizona,' in which the writer, after stating that among the contributions to the technology of cyanide treatment, little or nothing is to be found concerning the economic treatment of antimonial ores says, that "if some one of the numerous contributors * * * would tell how the antimony in this ore may be eliminated, or at least rendered innocuous, it would be appreciated by many having mines producing ores of similar character." As a member of that body of men who have put in years of study, research, and hard work on the treatment of gold and silver ores, I should say that the mine owners certainly would appreciate such information, given them gratis, but would like to ask 'Mine Owner' whether he considers it good business for metallurgists to give away the results of their work and experience in this manner? While it is true that the surgeon or physician gives any discovery which he may make, to the profession, through the medium of the technical press, the analogy ends there, for the profession is protected by law and the methods so given out cannot be taken up and practised by pharmacists and prescription clerks the world over. Let us take the case of manufacturing companies who employ technical men in their experimental departments. I have myself worked in this capacity and I know just how zealously all so-called 'trade secrets' are guarded. If this be good business in the case of the company, why is it not the same in the case of the individual, who makes his living by his knowledge of such matters? Information of this character is valuable, and although the methods of extraction available for the class of ores cited are rather involved and more costly than simple treatment, satisfactory results can often be attained by the man who knows how, where failures have preceded, and the extraction is almost entirely a business question, which a careful and competent metallurgical examination will answer in the surest possible manner.

METALLURGICAL ENGINEER.

La Jolla, California, August 16.

[We happen to know that our friend who signed his name 'Mine Owner' has strong conviction on the point raised by 'Metallurgical Engineer,' and for the present we shall leave the answer to him.—EDITOR.]

Far Eastern Politics and the Mining Industry

The Editor:

Sir—Americans are as a rule exceedingly provincial and display but little intelligent interest in what is taking place outside their immediate neighborhood. They have some vague general notions of geography, and experience a passing thrill when a catastrophe on a grand scale befalls some foreign locality, but even in matters of this sort the interest is rather that of a spectator looking to see if his own country will be outdone. To the credit of the profession, however, it must be said that our mining engineers are an exception, and that they are among the few Americans who follow keenly the trend of affairs outside our boundaries. It is natural that this should be the case, for every year sees an increasing number of our engineers called to the four quarters of the globe. They are the real missionaries of economic progress, and just as they play a large part in developing the resources of new regions, so the political conditions and relationships of these regions govern to a large extent their opportunities. It is the object of the present letter to point out the bearing of certain movements in the Far East on mining and on the opportunities for mining work in the future. To treat the subject exhaustively is out of the question; all that can be attempted is to call attention to a few points of interest.

The discovery of gold at Nome, following close after the Klondike excitement, awakened much speculation as to the possibilities of profitable mining on the opposite coast, and in 1900 a concession was obtained from the Russian Government under which a joint Russian and English expedition, of which I was a member, vainly explored the northeastern coast of Siberia. This is the concession which has since been exploited by John Rosene and his friends. Just before this several rich placers had been discovered farther down the Siberian coast, and interesting mining developments were taking place in Korea as well as in southern Manchuria. All of these things had a tendency to focus the attention of mining men on these regions just at a time when diplomacy was concerning itself with their ownership, as well as with the question of Siberian transportation and its outlet on the Pacific. With the change of the Russian railway plans and the occupation of Port Arthur I have nothing to do here. But one point is of interest and has great significance in dealing with the question of what the Russian Government is going to do in the way of developing eastern Siberia, and the attitude Russia will take toward foreign participation in this.

The public has been led to believe that the war with Japan was due to the aggression of the Russian Government in Manchuria and Korea. This is a great mistake, for as a matter of fact, the whole Russian movement in the Far East that led to the Russo-Japanese war was one of private enterprise in which a certain clique of promoters and politicians utilized their 'pull' to carry through in a high-handed manner territorial aggressions in which the Government had no interest. In many respects their method of working the Government for private ends of a fraudulent character was similar to that of the group of politicians who carried through the Noyes-McKenzie deal at Nome in 1900. It was our good luck in the latter case that the thieves were dealing with their fellow-citizens and did not tread on the toes of a foreign nation. An understanding of this point makes it easier to interpret the present attitude of the Russian Government toward the development of eastern Siberia, especially as far as Americans are concerned. The war attracted the attention of Russians to the Pacific littoral for the first time since the early fur-trading days, and in their attitude toward it they are divided into two camps. One party believes that to develop far eastern Siberia is to spread out too much, and that the energies and capital of Russia should be employed nearer home, especially on her southern Asiatic frontier. They argue that to develop rich mines in the Maratime Province is to arouse the cupidity of the Japanese before they are prepared to protect the region. In this class are those whose cry is 'Russia for the Russians,' and they are opposed to the proposed repeal of the law which for strategic reasons was enacted some years ago, by which foreigners are not allowed to own or operate mining property in a zone or strip 100 versts, or about 65 miles wide, along the frontier; a law which though general in its application, was directed especially against the Japanese. The other party is more progressive and is steadily increasing in importance. It argues that if emigration on a large scale from European Russia to the rich valley of the Ussuri were encouraged, and if Americans as well as Russians were led to develop the mining country of the Amur and the Pacific coast, the region would soon be able to defend itself. Although this point of view is opposed by many of the officials of eastern Siberia, it is gaining strength and will prevail.

From the standpoint of American mining interests, American diplomacy in the Far East has been a series of stupid blunders. Foremost of these was Mr. Roosevelt's interference in the Russo-Japanese war. Had this war continued two months longer, we should not now be facing Japanese domination of Korea and Manchuria, and at the same time Russian aggression would have ceased of its own accord, since it had been private and not national. This initial blunder has been followed by others that have finally resulted in throwing Russia and Japan into each other's arms, as evidenced by their recent treaty.

Stop for a moment and consider how this was brought about, and see how our State Department under the guidance of P. C. Knox managed to bungle the railroad situation to our detriment. A group of New York bankers desired to participate in a scheme to build railroads in northern China, and after a series of proposals, which included the neutralization of the railroads in Manchuria, the proposition was brought forward to build a railroad from Chin Chow to Aigun. It was pointed out that this would be entirely in Chinese territory, and while paralleling the Manchurian road now controlled by Japan for some distance, would develop a lot of new

territory and also act as a feeder for the Trans-Siberian. Our State Department was apparently surprised when Russia declined to concur in this plan. A glance at the map will reveal the reason. The proposed railroad would run for several hundred miles straight across country at right angles to Russia's sole line of communication with the Pacific. Its construction, with the Japanese near at hand as the dominant power, would close to her forever all hope of developing, or even holding her Far Eastern provinces. Think of what it would mean to Russia to have a railroad built right across her front reaching one of her richest mining regions, a road which if neutral in name, could be seized at any moment by the Japanese, a move which would instantly render the Trans-Siberian road useless from a military standpoint, and even prevent the use of the Amur river for summer transport. Is it remarkable that Russia vetoed such a ruinous proposal and viewed with suspicion the schemers who made it? It should be remembered that it was this same precious bunch that brought about the brutal recall of Charles R. Crane, our Minister to China, one of the best diplomatic appointments ever made by this country, because they found that he would be an obstacle to their nefarious designs. In answer to this absurd railroad project, Russia made a counter proposal, a railroad from Pekin to connect with the Trans-Siberian at Chita. This road would have followed a great caravan route and would materially reduce the time of travel from Europe to Pekin. It was an eminently fair and reasonable proposition, but it did not suit. The Japanese and their friends, the English, are intensely jealous of the Trans-Siberian because it has seriously interfered with the passenger business of their steamer lines, and to cut down the time of the trans-continental journey another day or two was not relished by them.

Russia saw the position at once and realized that America, upon whom she ought naturally to count as an ally to preserve the open door in Manchuria, had stupidly turned against her and was playing into the hands of the Japanese. What could she do? The natural thing under the circumstances was to close a deal with Japan on the best terms possible. This was just what Japan desired. Ever since the war she has done everything in her power to bring about a rapprochement with Russia, with a view to checkmating America, whom she fears and hates, and this was her opportunity. Russia would have liked to have been lined up alongside of America, but our cheap politicians threw away the chance and forced her to make a compact with Japan. Under the circumstances the outlook is dark for American enterprises for the development of the wonderful mineral resources of Manchuria and Korea. After several years of the most cruel and barbarous exploitation of the Korean people, Japan is on the point of annexing Korea definitely. The situation in Manchuria is not much better and there is not longer even the pretence of the open door.

On the other hand there are unlimited opportunities for American mining enterprises in Siberia, and the attitude of the Russian Government is favorable. The Russian mining laws are fair and liberal, in fact, in the matter of the size of claims and the basis of tenure they are too liberal, allowing large tracts to be held as locations on the payment of a small annual tax, and requiring no assessment work. Any American who will take the pains to acquaint himself with the provisions of the mining code, and will then use a little courtesy and tact in his dealings, will find Siberia an excellent country in which to mine.

From the standpoint of international peace and of a satisfactory solution of the problems of the Far East, it is a great pity that Russia has been so shamefully and maliciously misrepresented in the American press. The public, which relishes the sensational, does not realize that nine-tenths of all that is published in the papers about Russia comes through the hands of a committee organized by professional revolutionists for the purpose of influencing public opinion against the Russian Government. If a committee of disgruntled Americans desiring to injure our Government, were to make a business of circulating in the press of Europe lurid and exaggerated accounts of riots, lynchings, and graft exposures in the United States, to the exclusion of all other news, their position would be entirely analogous to that of the committee above mentioned, and they would find infinitely more material for their purpose.

The result is that Americans are now inclined to believe any tale concerning Russia and are in general becoming strongly prejudiced against her, an attitude which Russia cannot understand. This is all wrong, and in the interest of our future diplomatic relations should be corrected. Incidentally it behooves mining men to realize that Russia offers greater opportunities for mining development than any other part of the world today, that they can mine there in peace and safety, and that if the tide of foolish prejudice based on falsehood and misrepresentation can be put to an end, there will be no difficulty in persuading American capital to seek investment there.

JEROME B. LANDFIELD.

Binghamton, New York, July 24.

Copper was once supposed to occur at only a few places in the United States, but it is now known to be widespread. Most of the deposits are of low grade, but improved modern methods of treatment have made low-grade copper ores valuable. In Bear Lake county, Idaho, copper deposits occur near Montpelier. They are mostly carbonate ores. Their value has not yet been definitely proved, nor is their extent known. The chief project for their development is the Bonanza shaft, which has gone down 350 ft., but has not yet shipped ore. Shales, stained green, maroon, and chocolate by iron, abound in the region, the colors mimicking those of copper stains and misleading the prospector, who supposes that their vivid tints are indications of copper. The ores run only about 2%, but may be made to pay by proper treatment. The deposits have been described by H. S. Gale in Bull. 430, recently issued by the U. S. Geological Survey, and forming a part of 'Contributions to Economic Geology, 1909.'

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

Lithia mica is a silver gray to violet colored mica, and is valuable chiefly for the manufacture of lithia salts.

In concrete mixing the proportions, 1 cement, 2 sand, and 4 broken rock, will usually give satisfactory results. In many situations a mixture containing less cement is adequate.

The Granby, B. C., smelter is one of the largest in the world using blast-furnaces alone. The tonnage smelted during 1909 was 1,050,000 tons from which there was produced 22,200,000 lb. of copper.

Removing soil from the sites of new mills or for any less purpose, is done cheaper by hydraulic stripping than in any other way, provided the necessary water under a good head is available, and the sluicing of the débris onto lower land does no damage.

Tracks underground should be substantial. It pays to construct them so in mines as well as on the surface, and to keep them in good condition. Rough tracks that derail cars, frequently are expensive, costing more in loss of time than would be required to fix them properly.

Petroleum is obtained at a number of places in Wyoming, notably in the Popo Agie field in Lander county, and west of the Black Hills in Converse county. Wells were driven in the latter field as early as 1880, and the oil used as a lubricant at the mines of the Black Hills.

The tendency of centre posts to cut into the hanging wall plates of shaft sets in inclined shafts can be checked by inserting a heavy head-block between the top of the post and the cap. This head-block should be at least 14 in. long, 4 in. thick, and as wide as the wall plate.

Crucibles are readily made, the work requiring no great skill after a mold has once been procured. From drawings or a model a master mold of iron is first made. Such molds should be obtained from a clay-worker's supply house. From it plaster of paris molds are made and in these the crucibles are cast.

Segments for the annular ring used in gasoline melting furnaces, at the level of the top of the melting pot, may be cut from massive steatite (soapstone), which is abundant in some localities, particularly in California. A suitable iron may be attached to each segment to lift it from its place or to put it in position.

A series of experiments was recently made at Johns Hopkins University to determine the dielectric strength of air. It was found that the point at which a brush discharge occurred is only slightly affected by the moisture in the air. From dry air to saturated air there is a drop in voltage of the discharge of less than 2%. An increase of temperature from the freezing point to 40°C. caused the lowering of voltage by about 3 per cent.

Few men have been able to work in a caisson deeper than 100 ft. This, until lately, was considered the limit of depth to which caisson workers could go. A new record was recently established in excavating for the foundations of the Municipal building in New York City, where a caisson was sunk to a depth of 112 ft. 1 in., equivalent to 3.3 atmospheres, or 49.5 lb. per square inch.

The Powder River coalfield is a small part of a large area of coal-bearing rocks, known as the Northern Great Plains Province. Beginning at Casper and Douglas, on the North Platte river in Wyoming, this province extends northward between the Black Hills and the Bighorn mountains, occupies the eastern part of Montana and all the western half of North Dakota, and reaches into Canada.

Pulleys for power transmission are now made of concrete. They are made in two sections (split pulleys), the sections being kept apart during molding by a sheet of tin. The core for the passage of the shaft may be made by inserting a wooden plug of the proper dimensions. The pulley may be mounted by having suitable flange plates bolted on the sides, the flanges being provided with a key-seat, by means of which it is keyed to the shaft.

Careful experiments are being made by the metallurgists of the Rand to determine to what extent the carbon present in lime used in the cyanide process causes a precipitation of gold from the solution. From the investigation thus far made it is evident that a very small percentage of carbon in lime is permissible, having no deleterious effect on the solutions. The necessity for using only well-burned lime has, however, been made evident.

Micas may be distinguished by what is known as the percussion figure—a six-rayed star, made by striking or pressing a sharp point against a plate of mica. The trade employs a variety of terms by which mica may be commercially described. Thus, dealers speak of 'rum,' 'ruby,' 'amber,' 'white,' and 'black' mica, referring to the color. There is also 'ruled,' 'ribbon,' 'wedge,' 'A,' 'hair-lined,' 'fish-bone' or 'herring-bone,' and 'tangle-sheet' mica, referring to structural peculiarities, or to inclusions.

Black diamonds, or carbons as they are called, used in diamond-drilling, are practically useless unless of the best quality. Each stone should be carefully examined under a strong lens, search being made for flaws, porous condition, or other blemishes. Fragments of larger stones are better than small individual stones, as they can be more readily examined and flaws detected, than in the individual stones, where a surface gloss sometimes obscures physical imperfections. Stones that are flawed are likely to break, causing direct loss, while porous stones will usually wear away rapidly, running the cost of drilling up to prohibitory figures.

Special Correspondence

TORONTO, CANADA

Cobalt Shipments. — Government Rebate. — Porcupine Power Plants.—Electric Railway Surveys.

The record of shipments from Cobalt for the first seven months of the present year gives a total of 17,980 tons, as compared with 17,651 for the corresponding months of 1909. In view of the increased number of concentrators at work and the shipment of large quantities of concentrate instead of low-grade ore, this indicates a highly satisfactory condition of affairs. The bullion shipments for this year's period amounted to 347,797 oz., valued at $136,333. The leading producing mines maintained their position well. La Rose headed the list with 3493 tons, as against 3754 for the seven-month period of 1909, followed by Nipissing with 3233 tons, against 3424; Kerr Lake, 3132 tons, against 661; Crown Reserve, 1948 tons, against 1818; and McKinley-Darragh, 1013 tons, against 559. The Waldman and Wyandoh are among the new shippers on the list, and the Provincial, Casey Cobalt, and Hargraves reappear after having been inactive for some time. Among last week's shippers and consequently not included in the seven-month record is the Rochester, which has made an initial consignment of 30 tons. Notwithstanding the good showing lately made by Kerr Lake the stock has recently suffered severely from a bear raid based on the report that the best veins have given out at depth and that the ore to maintain dividends at the present rate will not be forthcoming. Beyond this retrograde movement, from which the stock is now recovering, the market has been devoid of interest, what between mid-summer dullness and the depressing effect of the slump in American stocks, which always reacts on the Cobalts. Lately there have been slight symptoms of a rally, due less to any revival of public interest than to the picking up of stocks at bargain-counter prices by traders in the hopes of a general revival this fall.

E. P. Earle, president of the Nipissing Mining Co., Ltd., reports that the Meyer vein has decidedly improved, yielding 8 in. of 3000-oz. ore at the second level. Vein 122 has been traced on the surface for 600 ft. and is being developed on the 100-ft. level. The new orebody recently struck on vein 64 shows a width of 2 ft. of high-grade ore in places on the 270-ft. level. A good discovery has been made on the 135-ft. level of the Princess property of the La Rose. In exploration work on the Fisher-Eplett belonging to the same company, two new veins, each about 3½-in. wide, have been found in the cross-cut from the Shamrock shaft at the 200-ft. level. The Buffalo paid an extra dividend of 3% August 15, making 16% paid in dividends this year, amounting to $160,000. On the Coniagas two more orebodies have been opened on the third level, veins No. 4 and 6 having been picked up at 225-ft. depth. The payment of the regular dividend of 3% per quarter has been resumed. A site is being prepared for the new 20-stamp mill of the Temiskaming & Hudson Bay shortly to be installed. The Ontario Government has made a material concession to this company as regards royalties on low-grade and concentrating ore. It will continue to pay 15% per ton on all ore mined, but a rebate of $3.50 per ton will be allowed for treatment charges on all ore passed through the mill. The Chambers-Ferland has recovered its 'Off-shoot' vein on the third level by cross-cutting over 100 ft. from the shaft. It varies between one and two inches, but is extremely rich. At the Temiskaming high-grade ore is being mined at the 400-ft. level, the veins at that depth showing no signs of deterioration. The main shaft is down over 500 ft. and another level will shortly be run.

The principal drawbacks to the development of Porcupine, namely, the lack of transportation and the consequent difficulty of obtaining cheap power, will shortly be removed. Two hydro-electric plants are to be installed in the neighborhood. A. E. Walberg, of the Mines Power Co., Cobalt, has secured a large water-power on the Mattagami river, nine miles from Porcupine, and A. M. Bilsky, of Cobalt, and H. D. Symmes, of Niagara Falls, Ontario, have leased the power at Sandy Falls, Mountjoy township, a few miles west of the Tisdale line, for the development of between 4000 and 5000 hp. for transmission to the mines. It is expected that both these enterprises will be able to deliver electricity next summer. An electric railway will be built connecting the district with the Temiskaming & Northern Ontario by a syndicate which includes A. Ferland, Chas. A. Richardson, W. C. Chambers, A. J. Burdett, and W. A. Gordon. The conditions on which the Government granted permission to build the road involved the immediate beginning of the enterprise and its completion by January 1. Survey parties are now laying out the line. Its western terminus will be on the Mattagami river about a quarter of a mile from the Timmins mine, but the exact point at which it will connect with the Temiskaming & Northern Ontario railway has not been decided. Development operations at the camp have been much interfered with by the scarcity of provisions and supplies. An important discovery has been made in diamond-drilling at the Dome where a vein containing free gold shows at a depth of 100 ft. A complete plant has been ordered for the Foster in southern Tisdale where a 20-ft. vein of dolomite is shot through with quartz stringers, both containing free gold which is also found in the wall-rock.

LONDON

Australian News. — Broken Hill. — Associated Gold Mines. — Vivien Gold Mining Company.

The Broken Hill Block 10 has been adversely affected by the recent coal strike in Australia. It has not been possible to work the mine and mill for more than 10 weeks out of the 26 included in the half-year September to March. During that time 32,683 tons of ore yielded 4773 tons of lead concentrate containing 2949 tons lead and 170,289 oz. silver, the recovery being 38% of the silver and 71.5% of the lead. In addition 27,877 tons of zinc tailing was produced averaging 17⅛% zinc, 4⅛% lead, and 9¼ oz. silver per ton. The amount received for the lead concentrate was £37,228, and the accounts were also credited with £1393, being 1s. per ton on the zinc tailing produced during the half year. The expenses were £38,909 and the costs incurred through cessation of operations £4274. In addition £8630 was written off for depreciation, and £458 placed to income-tax account, so that the loss for the year was approximately £11,000. As, however, the balance in hand at the beginning of the six months was £153,218, it has been possible to continue the payment of dividends, £20,000 being disbursed, being at the rate of 2% on the capital £1,000,000. The company also has an asset of £88,886 due for zinc tailing sold to the Zinc Corporation and the Amalgamated Zinc (De Bavay's). This amount is being received in monthly and quarterly instalments spread over a number of years. In addition the company has an accumulated stock of unsold zinc tailing amounting to 89,700 tons and this is continually increasing. Seeing that flotation processes have been proved commercially profitable on Broken Hill tailing the directors decided to treat their own. Accordingly four units of Elmore vacuum plant were ordered and were completed last month. This is estimated to treat 800 tons per week, and when it is in working order additional units will be provided to treat the total production of zinc tailing, 2000 tons per week. As regards the mines, development at Block 10 has not given satisfactory results recently. The 1615-ft. level is not yielding such high-grade ore as was found above. The lode is from 8 to 9 ft. wide, averaging 10 oz. silver, 8% lead, and 5½% zinc, and the rhodonite content is high. The main shaft is to be sunk 100 ft. deeper. The reserve of ore is estimated at 600,000 tons which can be extracted at the rate of 2500 tons per week. At the Southern lease, a lode 5 ft. wide averaging 9% lead, 5½% zinc, and 1½ oz. silver is being developed. Another property has been bought during the half-year, namely, the South Comstock, at Zee-

han, Tasmania, for which £5000 was paid. This contains a complex zinc-lead-silver ore which should be amenable to modern methods. V. F. Stanley Low, the general manager for the company, is now on a tour around the world visiting America as well as Europe.

Associated Gold Mines of Western Australia was formed in 1894 to acquire the Australia and adjoining leases at Kalgoorlie, and up to March 31 last the total production of gold has been worth £2,893,226 extracted from 1,037,955 short tons. The reserve of ore was estimated a year ago at 483,517 tons averaging just under 10 dwt. Since then the shareholders have suffered many rude shocks, as regards both the current extraction and the estimation of reserve ore. The directors have now to apologize for the failure of the method of sampling telluride mines at Kalgoorlie. During the first nine months of 1909, the monthly output of ore, averaging 11,500 tons, had been yielding gold worth £21,000. In November the yield began to drop, and one of the directors, A. H. Collier, was sent out to investigate. The cause for the fall was attributed at the time by the manager, George M. Roberts, to difficulty with water in one of the shafts and a collapse of ground in one of the stopes. Mr. Collier confirmed what was told him, but his report also showed that this particular stope was yielding the best quality of ore, and that its collapse revealed the poverty of the ore at the back. Subsequently, Mr. Roberts estimates the reserve at 553,000 tons averaging 6¾ dwt. but on June 17, he withdrew this estimate by cable and reported that the ore sent to the mill contained only 6 dwt., adding that the outlook was discouraging. E. H. Liveing, the company's engineer, went at the end of May to investigate. His cable report says that the reserve ore is low-grade and pockety, and that the prospects at depth are discouraging; his detailed report is awaited with anxiety. During the year ended March 31, the mill treated 136,829 tons and produced gold worth £228,351, being an extraction of 33s. 4d. per ton. The mining cost was £54,489, milling and cyaniding £79,878, and other expenses brought the working cost to £141,596. In addition development cost £30,021, and there were other small items of receipt and expenditure. The dividend paid absorbed £49,536, being at the rate of 10% in the issued capital. Though £69,000 has been spent during the last few years in improvements in the metallurgical plant, Mr. Liveing advises a renewal of the roasting furnaces on different lines, as the old ones are worn out. At the shareholders' meeting, the directors' extra remuneration, £990, was vetoed, and Benjamin Brookman and Edward Hooper were elected to the board in place of the retiring directors B. C. Hinman and John Waddington.

The Vivien Gold Mining Co. was formed in 1902, by Bewick, Moreing & Co., who are the managers, to acquire and develop a gold mine ten miles north of Lawlers, Western Australia. The issued capital is £76,000, and the equipment consists of 20 stamps and cyanide plant. No dividend has yet been paid. The upper part of the mine contains oxidized ore, down to the third level. On the fourth level, however, arsenical sulphide is found causing trouble in extraction. Developments recently have not kept pace with the extraction, 26,000 tons having been blocked as against 41,146 tons sent to the mill. The reserve on December 31 last was 35,219 tons, averaging over 6 dwt. An intermediate level has been driven between the third and fourth, approximately on the line separating the oxidized ore from the sulphide, and some useful ore has been found between this and the third. The ore treated during 1909 yielded by amalgamation and cyanidation, 10,625 oz. or 21s. 10d. per ton, bringing an income of £45,078. The expenditure on development, mining, and milling was £45,011. Expenses in London, depreciation, income tax, etc., brought the expenses to £47,419, so that there was an adverse balance of £2241. W. J. Loring, a member of the firm of Bewick, Moreing & Co., has recently paid a visit of inspection and reports that the plant is now treating the arsenical ore at a profit, though he is diffident in asserting definitely that the company is finally rid of its metallurgical troubles in this connection.

ELY, NEVADA

Nevada Consolidated Curtailment. — Ely Calumet Lessees. — Nevada Amalgamated.

For the past two weeks there has been a general curtailment in output by the Nevada Consolidated Copper Co. At the present time one unit of the concentrator is down and undergoing repairs, which cuts the production 25%. For the past month at least one section of the plant has been down all the time. The tonnage of ore now treated is at the rate of 6000 to 6500 tons per day, as against an average of 8000 to 9000 tons, a month ago. A steam-shovel arrived last week for the Nevada Consolidated, which will be used later in opening the new steam-shovel pit on the company's Liberty claim. For the present the shovel was put to work in the old pit, where there are six shovels in operation, two on ore and four engaged in the removal of overburden. Two other shovels will arrive in September, when the three machines will be put to work opening the new pit.

A discovery of unusual importance was made here last

Copper Flat from the Southeast, Ely, Nevada.

week by Stroheike brothers, who have a lease on Ely Calumet ground. Two men are now taking out from 12 to 15 tons of ore per day that will average at last 25%. The orebody appears to be 10 to 12 ft. wide, but not a sufficient amount of work has as yet been done to determine its extent. It occurs in an iron and limestone formation, the value minerals being bornite, carbonate, and red oxide, with some glance. The ore is being shipped to Salt Lake for treatment. Lessees on the Wildcat claim, owned by the same company, are taking out lead-silver ore averaging $70 per ton. At the present time they have a vein three feet wide which gives promise of developing into a good mine. A cash sale was made here today of the Gold Coin group of five claims adjoining the Giroux Consolidated holdings on the south for $20,000. The deed was made to Eugene Giles of Salt Lake, who is cashier of the Copper National Bank, and who is supposed to be buying the property for other parties, possibly the Giroux company. The Gold Coin group was owned by O. L. Terry, Raymond and Phil McKernan, Walter Schallenberger, and George Metzger, all of Ely.

E. L. Fletcher, who is the manager of the Tungsten property near Osceola, which was recently purchased of O. A. Turner, and which is rapidly being developed, returned last week from the East, where he purchased a plant for concentrating the ores, the product from which will be shipped East. Since arriving home Mr. Fletcher secured a bond on a group of tungsten claims at Tippet, in the eastern portion of this county for a consideration of $50,000. A force of miners has already been put to work developing the property. Reports from the Nevada Amalgamated at Blackhorse is to the effect that the new 10-stamp mill is rapidly approaching completion, and will be in operation in about two months. The mill will treat custom ores, which has had a stimulating effect in the development of gold properties in that district. A pumping plant has been ordered for the Zack shaft of the Ely Consolidated, which will be

installed within a couple of weeks, when the shaft will be sunk from the 400-ft. level. The company has developed a large body of 5 to 7% copper ore above the water-level, which will now be blocked out on lower levels. The Brilliant shaft of the same company will also be equipped with a pumping plant.

DENVER, COLORADO

Mining Congress. — Production. — Shortage of Silica Ores. — Changes in Speculation. — Will There be a Boom Next Spring?

The American Mining Congress, with headquarters in Denver, has recently organized a Colorado Chapter, and is urging the formation of local subsidiary associations among the miners in the principal districts of the State. The idea is that the latter are to be the fundamental organizations, and that the State Chapter should be composed of delegates from them. If there is a hearty response to this program, the work will be gradually extended into the rest of the mining States. Those who have, with much labor and persistence, and against considerable apathy on the part of even the mining public, kept the Congress alive during the last five years feel that, a bureau of mines having at last been secured, all who are interested in the business of mining should now get into position to back up the Congress in its efforts to obtain further results. D. W. Brunton has been elected president of the Colorado Chapter, A. W. Warwick, secretary, and E. A. Colburn, treasurer, while J. F. Calibreath, Jr., Max Boehmer, and A. L. Burris constitute the executive committee. Messrs. Warwick and Calibreath are now traveling around the State and organizing the local societies, and they report much interest among mining men. Primarily, the object is to secure financial support for the work of the Congress in Washington, but quite as strong a motive is to mass the moral backing of the mining districts behind the Congress in its demands for certain State and Federal legislation which is deemed of imperative importance. Among the things locally important may be mentioned enactments to properly punish the crimes known under the term of 'high grading', and an examination of the subject of district mine drainage, with the view of ultimately getting some law on the statute books which will compel absent or selfish owners to participate in the cost of unwatering certain basins known to be valuable, and yet at present inaccessible because of their divided ownership. In Federal matters, the Congress talks of endeavoring to secure some modifications of the rules and regulations recently issued by the Forest Service relating to prospecting in the National Forests, and certain fundamental changes in the National mining law. As might be expected, strong divergences of opinion on all these subjects have already developed, and it will take careful navigation to carry the organization safely past the Scylla of the extremists and the Charybdis of the indifferents. To an observer it looks as if some of the objectives—as, for example, the abolition of extralateral mining rights—have been posed merely to allow of their withdrawal later on, in the interest of harmony; and also that others, for the present kept carefully in the background, are to be pushed forward at favorable moments. This is perhaps the only way in which results can be obtained. There is a general feeling that up to date the Congress has justified its existense, and that it should be allowed further opportunities. At the basis of this friendly sentiment is a recognition of the fact that so far the organization has remained under the control of men of moderate views, but who have demonstrated both earnestness and ability, and that it will be safe to back them somewhat further.

Unusual activity characterizes almost every mining district in the State. Some of this is due to the recent improvement in the price of silver; some to the rapid advance toward completion of certain large enterprices (like the Cripple Creek drainage tunnel, for instance, which within the next thirty days will enter the mineral-bearing zone of the famous camp, and begin to draw off some of its waters), the importance of which are just becoming evident to onlookers in the commercial centres; some, perhaps, is more fancied than real; finally, some may be regarded as the reflex action due to a more vigorous exposition than usual on the part of the newspapers of the mining centres of the doings in their vicinity, as a protest against statements in some of the Denver papers, and remarks by an unwise and poorly posted official of the smelter interests to the effect that the industry has seen its best days and is on the decline. A glance over the July records from the principle districts shows that the daily output has not been less than 7000 tons, and was probably nearer 10,000. Such figures have deep meaning when examined, for it takes a good miner, working on a good sized face of ore, to break down three tons of ore per shift.

An interesting feature of the mining situation in the State is the impossibility at present of finding a sufficient market for the vast amount of sulphide ore which could be put out from Leadville and other camps. There are certainly several million tons of this class of material blocked out and available at small cost, and containing enough gold and silver to be payable under ordinary circumstances, if only a sufficient quantity of silicious ores could also be obtained by the smelters. Before the days of milling in Cripple Creek the pinching shoe was on the other foot, and low-grade sulphides were in high favor and demand. A new district yielding $20 to $40 ore in a gangue of pure quartz is badly needed. As it is, the smelters are going as far as Cobalt in Canada for their silica, and not getting anything like as must as they could use advantageously, even there.

As an index of sentiment among promoters and brokers in Colorado Springs and Denver, it is worthy of note that several have completely withdrawn from the mining field, and are pushing irrigation and immigration schemes of more or less merit. This simply means that these people, who bring a good deal of money into Western circulation, consider that the Eastern investor has become tired of mines for a while, and may be more easily influenced to take up other forms of speculation. There is a time for everything, and the present is not the time for a flood of new mining promotions. So the Exchanges are a little dull, and the brokers who have not changed their menu cards to suit the prevailing fashions are kicking their heels against the curbs and praying for a shift of the wind. It will come in due time. One has only to be patient. In high regions like those of the Colorado mining districts, the prospector has to suspend operations early in November at the latest, and cannot get into action again before June. The winters are usually devoted to working for wages, and when summer at last arrives, and the *wanderlust* comes upon him, he goes forth fairly raging. By the middle of July the public begins to hear from him. About that date the Denver papers bristle with tales of new finds, new districts, new kinds of mineral. As these are the dog days in the valley towns, all such items are most welcome, and are worked up with enthusiasm by the reporters. The fever lasts till the warm spell is over in the city, about August 15, by which date other interests come to the front, and the miner and his doings recede to a less prominent position in the public eye, while the farmer with his marvelous crops begins to draw the attention. His public season is somewhat longer than that of the miner, for his produce does not mature all at once. But by the first or middle of October he also passes into eclipse, while the real-estate man comes into his own again, and holds the prominent place on the stage until well into the following spring. And thus it goes from year to year, the actual producers of new wealth getting but a brief benefit of applause from the unthinking multitude. However, every now and then these real workers and developers do get a 'special,' particularly the miner, and then how things do hum, and how the traders in corner lots do hustle up the gulches to get in as nearly as possible on the ground floor of the new finds, and how the miner does get even. One has to be an onlooker for two or three decades in this little game to understand all the fun that goes on. There are some indications that the work of the prospector in Colorado this season may bring in one of the miner's 'special' years.

WALLACE, IDAHO

Success Mine.—Gold Hunter Mining & Smelting Company.

The Success mine, the most important zinc producer in the Coeur d'Alene, yields ore which averages 20% zinc and 6% lead, with some silver accompanying the lead. Approximately, 150 tons per day is mined and concentrated, the mill work resulting in a fairly clean separation of the zinc and lead. The zinc concentrate contains 45 to 50% of that metal, and this is shipped to Cleveland, Ohio; the lead concentrate contains 50 to 60% galena, and 40 oz. silver per ton. A day's mill-run of 150 tons of ore results in about 30 tons of zinc and 3 tons of lead concentrate. Both products are low in iron. The mill work offers a good example of roll-crushing, sizing, and thorough classification for concentration and separation by jigs and tables. The gangue consists of quartzite, which readily separates from the metals, and the fact that the percentage of iron is low makes it possible to produce tolerably clean zinc and galena concentrates. The mill is operated by water-power, supplemented by electricity. The mine and mill are 4½ miles north of Wallace, on the north fork of Nine Mile creek. The orebodies occur in a north and south zone of quartzite, the latter lying between bodies of monzonite. There are, apparently, two parallel veins from 15 to 40 ft. apart, and these follow the strike of the quartzite; also one or more veins which cut transversely the other two. Especially strong shoots of ore occur where these laterals cross the principal veins. The mine is operated through cross-cuts No. 2 and 3, the latter having a vertical distance of 448 ft. below the former. No. 2 cuts the ore 400 ft. from the portal, and No. 3 reaches the orebodies at a distance of 1200 ft. Several hundred feet of driving has been done on the two parallel veins off both No. 2 and 3 cross-cuts, which discloses bodies of ore ranging in width from 3 to 30 feet.

The greatest work going on now is on an intermediate level 100 ft. below No. 2, where a number of Waugh drills are in use in the stopes. Levels have been opened at every 100 ft. between the two, connected with No. 2 and 3 cross-cuts. All ore taken out of the higher levels is passed through chutes to a connection with No. 3, through which it is hauled to the mill. The two parallel veins, first opened on and above No. 2, are in evidence at other levels on which considerable work has been done. They have a dip west of about 70°. The cross-veins have been opened for some distance, but not as yet to the contact of the quartzite and monzonite. The zinc and lead are not uniformly associated; in some parts of the mine the bodies of zincblende appear to contain but little lead, though there is often a streak of high-grade galena next to the zinc ore. Especially in the higher levels the zinc greatly predominates, but on the lower levels the proportion of lead seems to have increased. It is an easy matter to obtain here specimens which will assay over 60% zinc, and others which contain about 80% lead, but the general averages given above are on the authority of H. F. Samuels, president and manager for the Success Mining Co., and are based on milling and shipping records. Samuel Linn, under whose charge most of the development has been done, is superintendent. The mill work is in the hands of Charles Samuels.

The Gold Hunter Mining & Smelting Co., operating the Gold Hunter mine at Mullan, is concentrating 200 tons per day of ore that assays 8% lead and 12 oz. silver, and as the mine is so developed as to be able to produce a much greater tonnage, the capacity of the mill is to be increased. All ore now produced is taken from levels above the main haulage adit, which is in 4700 ft. At the 4500-ft. point on this adit a winze has been sunk 200 ft. on the orebody, showing at that depth high-grade galena. The purpose now is to install an electric hoist at the collar of the winze and continue sinking till a depth of 1000 ft. shall have been reached. This adit, known as No. 6, cross-cuts the vein 1500 ft. below the surface. P. J. Hennessy, Thomas F. Keeley, J. R. McCormack, and Dennis Ryan comprise the officers of the company, Mr. Ryan being manager.

NEW YORK

Coppers.—Consolidated Arizona.—Tonopah Belmont Market.—Cobalt Stocks.—Granby.

The copper situation remains the pivotal point in the mining markets. The biggest public that ever got into mining came into coppers during the past five years, attracted in part by the glamor of the powerful names connected with the industry, in part by the element of safety in the big properties, with immense orebodies and an assured long life and, in part, more recently, by the general impression that there was to be or is to be something done in copper in the way of large market plans. It is hard to draw anything from any of those who can speak with knowledge concerning the present or future plans of the producers. There is an obvious lack of free speech, amounting to almost total paralysis of the vocal organs, in regard to both curtailment plans and understandings as to future mergers. The producers are finding it hard to carry water on both shoulders, to give the impression that there is a complete understanding as to restriction of output, and at the same time, keep clear of any legal difficulties. Butte is emphatic in its denial of curtailment except in so far as is necessary to avoid swamping the smelters. The Guggenheim interests publicly announce orders to curtail 15%, with the additional statement that it is done wholly on their own initiative. The general public has consequently been very much at sea and, while more than anxious to lend support to the copper share list, has been without a sufficient market guide. The trading in the securities listed upon the New York exchange has been featureless. Some two or three weeks ago the Pearson syndicate, which suffered financial embarrassment, was first relieved of extra burden in the way of securities carried and then saved from complete failure. As might have been expected there has since been made an eight to fifteen-point rally in the stock market obviously that the Pearson securities might be distributed. Even so sharp an advance has failed to secure the attention of the public, in most part, because the market is leaderless. There are issues in which there is much trading; Steel, Amalgamated, Reading, and the Harriman stocks; in all of these there are known to be large pools operating and so far controlling the market as to render any study of conditions on the part of the public futile. It is impossible to say whether those factors in the production of copper, who were in conference last winter in the attempt to frame a copper combination, were charmed with the possibilities of the scheme or were awed by the immensity of the undertaking. There is no question, however, as to the hold which the copper merger has upon the imagination of the people at large: a new market leader, another United States Steel to dominate and regulate an industry that is growing and breaking all records. The fascination of the copper merger idea was demonstrated, during the current week, by the marked attention and the amount of front page space given to a London cable, which placed Thomas F. Ryan, and Samuel Untermeyer, in the Hotel Ritz, in London, where, with a few copper magnates, they were building a $200,000,000 copper trust, which was immediately to raise copper prices all over the world. The story was ridiculous upon its face. T. F. Ryan is the whole power-house of New York city's transportation lines, surface, subway, and elevated, but he is not in copper at all as far as known. John D. Ryan, the diplomat of the copper world, has just returned to New York and was preparing to go to Utah to examine the new smelter at Tooele. Obviously a copper trust could hardly be projected without John D. Ryan—to speak for the Anaconda and the chain of coppers known as Cole-Ryan properties, nevertheless the story was so far credited as to be generally announced as the culmination of the months of negotiation by the copper producers. The story was plainly a canard and wholly unimportant, save that it demonstrated the wonderful general interest in copper and the universal desire to see created a new leader in the market. It is altogether conservative to say that nothing could receive such cordial unanimous market support as would a copper merger auspiciously

launched and especially if fathered by Mr. Morgan, who is held to be by far our greatest constructive financier. There are many ambitious plans, the copper combination among others, that are to wait until the Supreme Court shall pass judgment upon the Standard Oil Co. and the Tobacco Trust. In the meantime, however, there are many preliminary steps that like the Anaconda deal, are being completed in preparation. The Miami is to absorb the New Keystone and possibly the Inspiration, in the near future. The Miami and the Inspiration are physically all one property, and sooner or later will undoubtedly be brought under one management. As between the two there has always been a little argument as to which was the major part of the whole. Miami is the pride of the General Development Co.; the Inspiration is controlled by the Gunn-Thompson interests, W. B. Thompson being the market maker and the financial end of this combination, which was heavily interested in Nipissing and La Rose of Cobalt, prominent also in the original flotation of Cumberland Ely and now developing the Mason Valley, which is just erecting a smelter at Yerington, Nevada. Inspiration moved up sharply on the New York Curb this week. On the strength of the favorable developments at the property, Miami 'rights' have reached the market place and are being traded in around 20c., which is equivalent to $20 per share for the stock.

Consolidated Arizona, at one time Lawsonized but now in the hands of New York interests marketwise, has been the medium of an increased volume of speculation recently, largely due to industrious tipster work, but in part to the fact that the plant is producing some result now, the reverberatories being tapped this week for the first time. The plant is at Humboldt, Arizona, and should do a good custom business handling the ores of the Yavapai county mines.

The spectacular feature of the week was a drive at Tonopah Belmont. The news that the big Belmont vein had faulted on the 1100-ft. level, some 638 ft. in on the drift, precipitated a flood of selling that broke the market nearly a whole point. It is not believed here that the faulting is of sufficient importance or portent to justify any such bear attack, but the news was used for market ammunition and its possibilities greatly exaggerated. The vein will undoubtedly be picked up without great trouble. Belmont's July earning of $140,000 as compared with that of the Tonopah Mining company of $170,000 gave promise that Belmont might within a short time take place as the leading producer in Tonopah.

Kerr Lake is at present a patent illustration of the Cobalt paradox. The company holds the record for the production of cheap silver in Cobalt. Monthly cost sheets have occasionally shown a figure below 10c. per oz. It will pay a third quarterly dividend of 50c. per share in September and will have paid in 1910, $900,000. There have been some disquieting rumors of the bottoming of some of the veins, which are specifically denied by the management. Kerr Lake has a surplus of more than a million dollars and has assured three times that amount net in the mine, which is about as much of a showing as any Cobalt property can make as it is impossible profitably to block out any large orebodies at Cobalt. Yet, under selling pressure the issue, one of the largest dividend payers in the mining list, seems to be without inside or outside support. The Temiskaming Mining Co. is a second illustration. This property showed a deficit of $97,000 at the close of last year. The first six months of the current year wiped out the deficit and accumulated a surplus of $179,496. The showing of real profits in real money had little or no effect upon the market.

The recent so-called cave-in at the Granby property is explained by Jay P. Graves, the president, as being not at all a serious matter, in fact a part of the mining system employed at the Granby. Instead of following the old method of timbering, a plan has been worked out by the Granby engineers, whereby large ore-pillars are left standing to support the roof and floor levels as work advances. When all of the ore above is extracted, these pillars are shot down and the roof or floor above falls and the ore contained is shipped. Frequently these floors or roofs are permitted to stand for some time after the bulk of the ore has been extracted before being shot down; often when a large percentage of the ore is extracted from a given stope, that part of the mine is closed and permitted either to fall, as was the case in the instance referred to, or is shot down at a later date when a large amount of ore is needed for extraction. Mr. Graves states that this plan has worked satisfactorily, is very economical, and has proved perfectly safe to miners and owners.

The directors of the Calumet & Hecla Mining Co. have elected Rudolph L. Agassiz vice-president to fill the vacancy made by the resignation of Thomas L. Livermore. Mr. Livermore presided at the stockholders' meeting just preceding that of the directors, his doing so being his last official act after twenty-one years of service with the company.

LOS ANGELES, CALIFORNIA

Oil Operators Meet. — Midway Gushers. — Power at Kingman.

The meeting held here on the evening of August 18, for for the purpose of discussing conservation and its effect on the oil industry of California, was attended by about 75 operators. Two committees were appointed, one on organization of a permanent body and another on resolutions. It will be the duty of the latter to formulate resolutions for presentation at a meeting to be held here on the evening of August 25. A large delegation from San Francisco is expected at this meeting. It is the purpose of the organization to prepare a set of resolutions that will embody the views of the oil operators of the State, and present them at the forthcoming meeting of the American Mining Congress. Obviously, the operators are not of one mind on the question of conservation, for there are certain policies that would be favorable to some and possibly disastrous to the interests of others. Already there has been discussion among those who differ with some of the ideas advanced regarding conservation.

After sanding on August 9 and giving some little trouble, well No. 79 of the American Oilfields, in the Midway field, has started flowing with renewed energy. Up to August 21 the official report was that the well had gradually increased to 25,000 bbl. per day, at times flowing at the rate of 50,000 bbl. per day. This output is slightly in excess of that of the Lakeview gusher, which is reported to be flowing between 20,000 and 22,000 bbl. Well No. 68 of the American Oilfields, about 1200 ft. northeast of No. 79, was brought in about ten days ago and from last reports was flowing at the rate of 6000 bbl. per day. The well is making a great amount of sand and officials of the company predict another gusher. The Combination-Midway brought in a strong gas well during the week. The blow-out occurred at 1800 ft., after the drilling had been in blue clay for a depth of 800 ft. The crown block and upper part of the derrick were blown a great distance and much other damage was caused.

Officials of the Desert Water & Power Co., operating at Kingman, Arizona, state that the Gold Road and Tom Reed mines have increased their demand for electric power. These mines, situated 25 and 27 miles respectively, from Kingman, have been using 700 hp. and within 60 days will be consuming 1000. The Hercules mine is almost ready to connect its power line. The power company has ordered machinery enough to double its present capacity, in anticipation of a growing demand for electric power in the vicinity of Kingman. The Young Construction Co. of this city will begin immediately the remodeling of the old stamp-mill on the property of the Ruth Gold Mines Co. This property, situated near the Gold Road mine, was recently acquired by a group of capitalists from the South. The capacity of the mill will be increased and a cyanide plant added. The Young company has charge also of the remodeling of the 100-stamp mill and cyanide plant of the United Mines Co., operating at Ogleby, California. This property was formerly known as the Golden Cross mine.

General Mining News

ARIZONA

GILA COUNTY

(Special Correspondence).—Expectations of ore to be revealed by the cross-cut south from the 500-ft. level of the Telfair shaft to the Old Dominion fault at the Arizona Michigan property have been somewhat nullified by virtue of the fact that the cross-cut has been or is supposed to have been in the vein for the past week. At a point 1150 ft. from the shaft the formation changed abruptly. The calcareous shale ended and the formation assumed the semblance of iron-stained vein matter. At the point where the change took place there was no revelation of anything that suggested a wall and it is doubtful if the cross-cut is even in the Old Dominion fault. If this is the condition the Arizona Michigan people still have an unexploited vein directly ahead of them and the continuation of cross-cutting may reveal copper in the near future.——Various conflicting and recurring reports are prevalent as to the state of Arizona Commercial as far as ore in sight is concerned. Reports to the effect that ore of great quantities and richness has been revealed by the diamond-drilling on the 7th level have appeared in the Eastern financial papers along with some encouraging articles dated from Globe and emanating from an unknown source. It is to be hoped that these reports can be relied upon and that the Arizona Commercial can find its way clear to open the smelter inside of 60 to 90 days. Local rumor, however, has added nothing to the details that the diamond-drilling had been discontinued and that the underground force had been laid off. A contract has just been let for the sinking of the Eureka shaft at $80 per foot, and good progress in that direction should be made.——Development is still being carried on in the McGaw shaft at the Superior & Boston property, the weekly progress amounting to something like 20 ft., and the depth to date being in the neighborhood of 825 ft. from the collar of the shaft. The formation in the bottom of the shaft is a badly shattered and somewhat silicious limestone, and the nature of the rock has allowed of the circulation of ground water to the extent that there has been quite extensive mineralization. The rock is heavily iron stained and in places assays well in copper.

Globe, August 22.

MOHAVE COUNTY

The concrete work on the foundation for the new cross compound engine that is to form the new unit of the power plant at Kingman, is well under way and the machinery will soon be on the ground. When the extra unit is completed power will be supplied to many of the mines in the districts surrounding Kingman, thus reducing the cost of development.——The force at the Enterprise mine has been increased by W. A. Mensch and considerable development is planned. The owners are figuring on erecting a mill this fall.——The assembling of the machinery at the Gold Crown mine is going forward rapidly and a number of teams are kept busy hauling the parts from the Union depot.——It is reported that the Needles Mining & Smelting Co. has opened the Tennessee vein at a depth of 200 ft. and that the old works will be unwatered to that level at once.

PIMA COUNTY

The Copper Queen Consolidated Mining Co. has purchased the Geesman, Leatherwood, and Billie Reed properties in the Santa Catalina mountains for $135,000. It is also reported that the Copper Queen company has taken over the property of the Imperial Copper Co., at Silverbell, and that the recent shut-down was for the purpose of appraising the company's holdings.

YUMA COUNTY

The Clara Consolidated Gold & Copper Mining Co. has purchased the old Mudespaugh mines, about eleven miles south of Bouse, for $250,000. The ore is a copper-silver sulphide with a small amount of gold and is said to make an excellent flux for the Clara product.

CALIFORNIA

AMADOR COUNTY

The Kennedy Gold Mining Co. is again sinking, the shaft having passed the 3500-ft. point.——The Bunker Hill Mining Co., at Amador City, is to add 20 stamps to its mill.

CALAVERAS COUNTY

The Oriel mine in the Mokelumne district has been bonded and work is to be started in a short time.——It is

Kennedy 100-Stamp Mill.

reported that the Easy Bird mine which has been idle a short time is to resume operations.——C. O. and W. R. Womble, who have a bond on the North Star mine at West Point, have retimbered the main shaft and are sinking on the vein which is 30 in. wide and contains a high percentage of sulphides.——Thompson & Smith are sinking a new shaft on the main shoot of the Bouvard Extension.——A. R. Wilson has secured a bond on the Champion mine.——The Newman mine and mill have been closed down on account of the lack of water.——The air-shaft which Young & Chapman are sinking on the Alaska mine is down 40 feet.

HUMBOLDT COUNTY

(Special Correspondence).—The California Mining & Dredging Syndicate, operating at Orleans, on the Klamath river, with about 1500 acres of patented land, has just closed a successful hydraulic season. The water fell below 600 in. at the mine early in this month, and the management concluded to shut down the giants and put the flumes and ditches in order for the coming season's operations. The county wagon road is now within eight miles of the mine and the completion to Orleans is expected early next year; this will enable the building of a dredge at Orleans to work the low flat and river-bars. The Syndicate has added to the saw-mills and generally improved the property during the past two years in anticipation of completion of this road enabling dredge installation. H. DeC. Richards is general manager.

Orleans, August 22.

INYO COUNTY

The Gray Butte mine west of Benton has resumed operations and the deep adit will be driven ahead to cut the veins at depth.——A. J. McCone and associates have taken up their option on the Reward mine, southeast of Independence, and it is reported that work will be resumed in a short time.

NEVADA COUNTY

The company operating the Birchville mine in the Graniteville district, the plant of which was destroyed by fire a short time ago, is to rebuild shortly installing electric machinery to replace the old steam and water-power plant. The installation of electric apparatus will do away with many troubles previously met on account of the water in the ditches and pipes freezing.——C. M. Root, superintendent of the Gladstone, Sierra Madre, and Acme properties, has added several men to the working force, and it is expected that the shoot will be tapped in a short distance as numerous rich stringers are being found in the quartz.

SHASTA COUNTY

(Special Correspondence).—At the Little Nellie mine which joins the properties of the Mountain Copper Co. in

the Iron Mountain district, a new Sullivan 2-stage, 6-drill compressor, 50 hp. General Electric motor, and Sullivan drills have been installed, making a total of six drills now operating in the mine. The lower drift has been driven over 2460 ft. on the vein opening three shoots, the last of which has been driven on for 320 ft., the ore showing as good in the face as at the beginning of the shoot. This drift gives the company 360 ft. of backs on the vein which is 1 to 5 ft. in width and on which 12 stopes have been opened. Ore-bins have been erected on the Iron Mountain railroad and the ore which nets the company $13 per ton is being forwarded to the Mountain Copper Co.'s smelter at Martinez. Fifty cars of this ore which is probably the only quartz ore being shipped in Shasta county at this time, was forwarded recently and the company expects to continue shipping at the rate of 1000 tons per month. Since last November enough ore has been shipped to pay all expenses of mining and development. A. B. McVey is superintendent, and J. F. Partington foreman.——E. O. Lindblom, who has held a lease on the Milkmaid group at French Gulch, has given up his option on the property as the mine has been worked out.

Redding, August 23.

SIERRA COUNTY

(Special Correspondence).—The sub-station of the Middle Yuba Hydro-Electric Co. is nearing completion on Smith's flat, near Alleghany. The transformers are being installed and it is expected to commence the delivery of electric power to the mines early in October.——The drift from the lower adit of the Tightner is approximately 120 ft. from the ore-shoot opened in the winze from the upper adit. The drift has followed the vein for over 150 ft. with free gold and sulphides showing the greater portion of the way. A lot of 125 lb. of ore, valued at $2000, was recently taken from a point below the main shoot.——The Twenty-One recently intersected the contact and the vein broadened to a width of 8 to 10 ft. The shoot is three feet wide and consists mostly of ribbon quartz with considerable sulphide. The adit is progressing steadily.——The Bear Creek mill is shipping bullion regularly. Steam power has been introduced. ——An air-compressor is to be installed at the Lookout where a 20-ft. vein is being opened.——Fifteen men are working at the Phoenix and the mill will be put in operation as soon as the flume has been completed. Six feet of milling ore has been opened in the old workings and it is planned to drive a lower adit from 1600 to 1800 ft. to tap the vein at depth.——It is rumored that work will be shortly resumed at the Four Hills.——The mill at the Swastika has been practically completed.

Alleghany, August 22.

TRINITY COUNTY

(Special Correspondence).—The Adams Exploration Co., which owns a group of claims half a mile north of Carrville, has opened a vein of high-grade free-milling gold ore and will prepare for the installation of a Huntington mill and the erection of a bunkhouse for the men.——The Golden Eagle Mine and Development Co. of Vallejo, has taken a bond on the Iron Dyke group, south of Carrville, for $100,000, and one on the Forget-Me-Not group, one mile east, for $5000. Both groups are the property of Mrs. George Carr.

Carrville, August 22.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—A deal has practically been closed whereby the American Sisters mine and Princess of India adit on Columbia mountain, will be turned over to M. W. Mouat, representing a syndicate of New York capitalists. The consideration is said to be $150,000. J. J. White, one of the heavy stockholders in the property, is now in New York completing arrangements.——Work was resumed this week upon the Sunburst Extension property on Democrat mountain. It is proposed to continue the adit to intersect the series of veins owned by A. Robert.——A shipment of four tons of ore made last week from the Anglo-Saxon mine on Saxon mountain assayed 2 oz. gold and 35 oz. silver per ton.——It is stated that seven carloads of machinery should arrive in Georgetown any day for the Western Metals Co., constructing the Maim electro-chemical mill. The equipment was started three weeks ago from Schenectady. From a statement made by W. E. Maim the plant will be ready to start ore treatment within 60 days.——A body of ore 6 ft. wide that assays 2 oz. gold per ton, has been opened in the Oneida mine at Freeland. The discovery was made through the Lamartine adit-level.

Georgetown, August 20.

GILPIN COUNTY

(Special Correspondence).—A contract has been awarded McFarlane & Co. of this place for the erection of a 250-ton concentrating plant to handle ore from the mines of the Frontenac Consolidated Mining Co. Power will be supplied by the United Hydro Power & Electric Co. of Georgetown. ——Four tons of ore were shipped last week from the War Dance mine that milled 10 oz. gold and 4.55 oz. silver per ton.——Work is to be resumed on the National mine on Quartz hill by D. McKay and associates.——A clean-up of 60 tons of ore from the Egyptian mine brought a settlement of 1.40 oz. gold and 12 oz. silver per ton. The first-class ore varies in value from $85 to $130 per ton.——W. L. Shull resumed work last week on the Hall mine in Russell district.——The boilers at the Brooklyn mine have been fired and water is being lifted from the shaft.——A shipment of 250 tons of ore is now being made from the Rockford mine to the Iron City mill. S. Harris is manager.

Central City, August 19.

LAKE COUNTY

The adit being driven into St. Kevin mountain by the Gleason Gulch Mining Co., to cut the President, Amity, Birdella, Iron Hat, and other veins, is making excellent progress, being in nearly 800 ft. A number of rich stringers have been cut and it is expected that the work will be finished within the next 300 ft.——The lessees of the Matchless claim of Fryer hill are shipping 40 tons of carbonate ore per day.——The lower drifts at the Homestake have been cleaned out and two shifts are working at the face.—— The territory east of the Silver Cord ore-shoot is being prospected from the Yak tunnel with excellent results. A winze has been sunk 600 ft. from the tunnel-level and an orebody cross-cut that assays $50 per ton.——A drift has been driven 200 ft. on the vein that was recently opened in the New Monarch property showing it to average 14 in. wide and assay $40 per ton.

OURAY COUNTY

A body of copper-silver ore that assays 600 to 700 oz. silver per ton has been opened by the 80-ft. raise from the Koler adit-level on the Carbon Lake claim of the San Antonio company. It is thought that this shoot extends to the 200-ft. level, giving the company 300 ft. of backs.—— Sinking has been resumed in the Legal Tender shaft, south of Ouray.

SAN JUAN COUNTY

(Special Correspondence).—Two important discoveries have been made in this county in the past few days. A splendid body of stromeyerite, gray copper ore, has been opened on the Kansas City group in Georgia gulch. The ore is rich in silver assaying from 150 to 800 oz. Where the vein was cut it displayed chalcopyrite and driving 35 ft. to the south the high-grade ore was opened which has gradually spread out until at the present writing it is three feet wide. Twenty tons have been taken out and is being loaded at the Henrietta switch of the Silverton Gladstone railroad. The group is owned by Walker & Russ who have worked it for the past two years.——The Hamlet mine has cut the Hamlet vein on the sixth level just above the mill in the Animas valley. This gives stoping ground 1300 ft. in height. At the point cut the vein exposed was a chalcopyrite-galena ore containing 12% copper and 40 oz. silver.

Silverton, August 19.

TELLER COUNTY

William Roe and associates operating a block on the 500-ft. level of the Ajax mine in the Cripple Creek district,

have uncovered a vein that assays $20 to $40 per ton.——Experts have completed the examination of the Ophir mine on Raven hill for the Western Investment Co., and a long lease has been secured on the ground.——The upper Davenport shaft of the Doctor-Jack Pot is being repaired and will be sunk from the 700 to the 900-ft. level.——One of the largest orebodies found in the district is being opened on the 1700-ft. level of the Blue Bird mine and ore that contains a high percentage of sylvanite shipped.

IDAHO

SHOSHONE COUNTY

(Special Correspondence).—During the last half of July and through August the destruction wrought by forest fires in many parts of the Northwest has been as great as it has been regretable. The fact that practically no rain has fallen in this district within the last ten weeks has rendered the grass and other undergrowth in the timbered areas dry and inflammable, and fires, started by accident and carelessness, have spread with fierce rapidity, catching in the smaller trees and drooping branches of the larger ones, which in a strong wind became beyond human control. The greatest havoc has been in Shoshone and Kootenai counties, Idaho; Stevens and Ferry counties,

Map of Coeur d'Alene District.

Washington, and that portion of British Columbia in which Kaslo, Sandon, and Nelson are situated. The loss is not only measured in square miles of timber, and ranch and mine property, but in human lives. Besides the aid rendered by the forces in charge of the Forest Service, the employees of mining companies and persons of all occupations have joined in efforts to save life and property. In many cases mine buildings and ranch houses have been successfully shielded by reason of the small clearing around them, but all efforts to check a raging fire in a thick forest has been unavailing. At this writing there are no indications of rain, the sun is dimmed by a pall of smoke, and the fires still continue in many places. A portion of Wallace has been destroyed and Burke and Mullan are in grave danger.

Wallace, August 22.

KANSAS

CHEROKEE COUNTY

(Special Correspondence).—The United Zinc Co. has bought of S. A. Stuckey a lease of 30 acres in the Lehigh camp, and has installed two pumps, one a centrifugal and the other a 5-in. steam pump, and have the water lowered to 120 ft. Early day operations were conducted above 100 ft., but a better grade of ore is found at 120 ft. The ground requires little timbering. Rich lead pockets were also frequently found in the past even above the 100-ft. level.——The Homestake mine has sunk a former shaft to a greater depth and as a result has reached a deposit of zinc ore in addition to the galena which was formerly mined. The new deposit runs 20% ore. At the present, operations are confined to two hand jigs, but a plant will be built later if the prospect continues as good as it promises.——The latest company operating in the Cave Springs camp is the Hello company, recently organized with a lease of 20 acres upon the Schmuck land where a number of drill-holes have cut ore in both shallow and deep deposits. A shaft is now being sunk to open the upper levels while the deeper deposits will probably be opened later.——In the same camp the Cave Springs company is making a large turn-in from hand jigs, making a carload of concentrate per week. The ore is found at the 80-ft. level, and much is so free that little treatment is required. A large dump-pile is also accumulating to await a mill.——A. O. Ihlsing has sold the greater part of his interest in the Eureka mine and will henceforth devote his time to the development of leases on the Murphy and East Empire tracts where a tailing mill is being put up to handle the tailing from the Brindle Steer, the Jack Tanner, Henry C., and other old mines.——The Eureka mine was taken over by Robert Ping, who, in a recent prospect drift to the northward, opened the best ore so far found. The large new mill has not yet been run steadily as the company has met with trouble in the pumping apparatus.——The new mill at the Diplomat company has been completed and has now made its trial run with great success.

Galena, August 20.

MONTANA

BROADWATER COUNTY

(Special Correspondence).—The Custer group of mines, two miles from Winston, which have been active, are temporarily idle by reason of litigation involving one of the claims. C. S. Muffly, the principal owner, states that he anticipates the resumption of mining and shipping this fall. There are two veins, the Custer and Hyantha. The former is opened by a 600-ft. vertical shaft and six levels. The latter has a 300-ft. shaft and two levels. The veins are in diorite, and the ore contains galena, iron sulphide, and gold.

Winston, August 20.

JEFFERSON COUNTY

(Special Correspondence).—The Boston & Corbin Copper & Silver Mining Co. has the Bertha group at Corbin well developed through a 900-ft. shaft. A Wellman-Seaver-Morgan electric hoist and a 15-drill Ingersoll-Rand air-compressor were installed some time ago. Driving is in progress on the Bertha vein from the 700-ft. station, the ore being partly a chalcopyrite. Some tests are being made with the view to erecting a concentrating plant if results shall indicate that it is warranted. H. E. Emerson is manager. The president of the company is N. L. Amster, who is largely concerned in the Shannon at Clifton, and the Arizona Commercial mine at Globe.——The Elkhorn, a silver-lead mine at Elkhorn, is operating with a good force and is running a mill.

Corbin, August 19.

LEWIS AND CLARK COUNTY

(Special Correspondence).—In the Marysville district the mill at the Bald Mountain mine has been temporarily closed, pending further development in the mine. Thomas Cruse, the owner, has bought the Belmont, which is being further developed.——Frank Laughlin and Mrs. Matt Dougherty are shipping ore from the Honeycomb mine which assays $40 per ton in gold. This ore is taken from the mine dump.

Marysville, August 20.

NEVADA

ESMERALDA COUNTY

New work in the old Reilly stope in the Florence mine at Goldfield, is opening a large body of rich ore. The report submitted by the company to the State bullion and tax officials for the quarter ended June 3, showed that the company has mined and milled 13,252 tons of ore during that period, the average being $11.85. The cost per ton, including depreciation and administration charges, amounted to $9.85.——The report of the Goldfield Consolidated, filed with the State officials for the quarter ended June 30, showed that 36,826 tons had been treated, the average extraction being $75.74, the cost per ton being $28.39.——An orebody assaying 10% copper and $50 gold per ton has been cut on the 250-ft. level on the Spearfish claim at Goldfield. The ore is iron sulphide with black oxide of copper.

NYE COUNTY

(Special Correspondence).—The east drift on the 1100-ft. level of Belmont exposes a vein 12 to 16 ft. wide. It has been followed for about 700 ft. the ore being of excellent grade. On the 1166-ft. level the drift is opening 6 ft. of high-grade ore on the hanging wall.——At the Tonopah of Nevada diamond-drilling is progressing from the 1500-ft. point, while extensive developments are under way above the 700-ft. level. The company has entered into a new agreement with the Nevada-California Power Co. for the furnishing of electric power to the Tonopah mines and Millers plant for 10 years.——The drill hole at the MacNamara is 175 ft. below the 800-ft. level and going down rapidly.——At the West End developments are concentrated at the 275 and 400-ft. levels. Driving has been commenced to intersect a rich vein which strikes into West End from the MacNamara.——The Tonopah Extension reports improved conditions in the lower workings. The company is shipping 840 tons of ore per week.

Tonopah, August 20.

WHITE PINE COUNTY

Payment of bullion tax for the quarter ended June 30 this year has been made by the Nevada Consolidated Copper Co. to the assessor. The tax amounted to $7706.24 and was on an assessment of net profits for the three months amounting to $428,124.47 which accrued to the company from a total production of 696,045 tons of ore from which the value of the metals extracted amounted to $2,134,114.21. Five other mining properties in the county produced during the quarter 4204 tons of ore which were reported to the assessor at a valuation of $20,037.19 on which no tax accrued, making the total valuation of the mineral output for the period, $2,154,151.40. Next to the Nevada Consolidated the largest producing company was the Glasgow & Western Exploration Co., owner of the Star mine on Cherry creek. The amount of ore produced was 3892 tons worth $14,706, principally in silver.

UTAH

JUAB COUNTY

A contract has been let to Ralph Kellogg and Sam Scott to sink the shaft at the Yankee Consolidated from the 500 to the 900-ft. level, electric sinking equipment having just been installed. At this time six sets of lessees are operating in the old workings of the mine and are all reported to be doing well.——The North Iron Blossom Iron Co. has been incorporated to develop a group of 11 claims in the north Tintic district adjoining the old Beck iron mine.——A body of ore has been opened on the 300-ft. level of the Colorado mine 50 ft. below the body from which the main production has been made the last few years, and 350 ft. from the Sioux Consolidated line.——It is reported that the Gold Chain has opened a body of ore on the 300-ft. level though not enough exploration has been done to determine the size of the shoot. On the 400-ft. level a drift has been started to intersect the same vein.——A diamond-drill has been installed on the 1000-ft. level of the Tintic Standard and the lower levels of the property will be thoroughly prospected.

SALT LAKE COUNTY

Colin McIntosh, manager for the Ohio Copper Co., is authority for the statement that F. A. Heinze has been successful in raising the necessary money for the completion of the concentrator at Lark, and that a statement will soon be made to the stockholders of the company with an outline of the work.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—The Cliff mine at this place is being developed on a small scale under the supervision of W. Y. Williams, consulting engineer for the Granby Consolidated company. This mine has one of the finest showings of copper-gold ore in the camp and would easily be working now but the Spokane owners have always held it at a high price and would not lease. Operations at the Granby mines were interrupted during the past week by a fire which broke out in the oil-house and burnt the No. 3 crusher building and machine shops. Repairs are being rushed with all haste, however, so that shipments may be resumed as soon as possible, to avoid blowing out any of the furnaces at the Grand Forks smelter.——The Yankee Girl Gold Mines, Ltd., has purchased a 5-drill compressor, drills, and accessories. This property has made an excellent showing this year, shipping 3432 tons of ore so far and opening new ground all by hand labor. Larger shipments and cheaper working costs will result when the power plant starts.——Excavation work has been started on the concentrator for the Aurora mine at Moyie. The showing at the Aurora is said to be very encouraging at this stage.——The 700-ft. adit on the Mother Lode group, Sheep creek, has tapped the vein at a depth of 480 ft. from the apex. This is the fourth adit that has been driven on the Mother Lode zone and the expectations of the management have been fulfilled in each instance.——The work of getting things in running order at the Whitewater mine and mill is now under way, but is being hindered somewhat by lack of railway facilities, the Great Northern having been disabled by the burning of its bridges.

Rossland, August 19.

KOREA

(Special Correspondence).—The Korean Exploration Co. is preparing to reorganize and increase its capitalization by $250,000 for the purpose of installing a large modern dredge upon its Chicksan placers. The company is at present operating a small Nissen stamp-mill upon one of the quartz veins and has an additional three-stamp Hendy mill upon the ground which is to be erected upon another property.——The Seoul Mining Co. has recently purchased the 20-stamp mill and machinery of the British-Korean Syndicate at Gwendoline and will add it to the present 20-stamp installation at Suan. The total bullion output of this company for June exceeded $25,000.——The Oroyo-Brownhill syndicate has purchased several claims adjoining its old property in the Sakju district and is pushing development. It is rumored that the syndicate has secured an option for prospecting purposes upon the French concession of Chang Song, one of the largest in Korea, and will commence work as soon as the present Korean lease expires.——Great activity is being shown lately in Korean placers, both foreigners and Koreans applying for claims in great numbers. A company has recently been formed locally for the purpose of prospecting and buying dredging properties.

Seoul, July 22.

MEXICO

CHIHUAHUA

The July production of the Rio Plata Mining Co. amounted to 82,000 oz. of silver. This is the largest monthly production on record, the best previous showing having been made in January, when 71,164 oz. were produced. Last month's shipment of bullion, to Monterey, brought $40,340.——The Maria mine, in the Roncesvalles district, which is now being worked by J. W. Hambleton, of Parral, shipped the first car of ore recently and now has three more cars ready for shipment.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

J. W. Finch is at Butte.

C. S. Herzig has been in San Francisco.

Charles Janin has been at Los Angeles.

S. W. Mudd was in San Francisco last week.

J. R. Phelps was in San Francisco this week.

Ralph Arnold was in San Francisco Tuesday.

J. R. Finlay was in San Francisco Wednesday.

Godfrey D. Doveton has been in San Francisco.

William Foastner is in New Mexico examining mines.

W. H. Storms is visiting the San Juan region of Colorado.

L. K. Fletcher is at the Rincon mine, Temescaltepec, Mexico.

I. Ford, of Redlands, California, was in San Francisco this week.

W. Murdock Wiley returned from Los Angeles to San Francisco this week.

Hugh R. Van Wagenen has been examining mines in the San Juan district of Colorado.

Alexander P. Rogers is making examinations in Siberia and will not return to New York for some weeks.

T. C. Crowe, of the Portland Gold M. Co., Victor, Colorado, who was in San Francisco, has gone to Nevada.

Theo. F. Van Wagenen has returned to Denver from a trip into the region between Cobalt, Ontario, and the head of James Bay.

E. G. Duisenberg, of Honolulu, passed through San Francisco this week on his way home after an inspection of the oilfields of California.

J. B. Tyrrell has left for a short visit to London. His address will be care Mining and Metallurgical Club, St. Ermin's, Westminster, London, S. W., England.

Walter O. Snelling, of the U. S. Bureau of Mines, who has been traveling through Alaska, visited San Francisco and Grass Valley, California, on his way back to Pittsburg.

E. M. Hamilton has left Candor, North Carolina, for Ventanas, Mexico, where he will be for a month, after which his address will be care Lluvio de Oro G. M. Co., Chihuahua, Mexico.

Los Angeles Members of the Mining and Metallurgical Society of America have arranged for a subscription dinner at the Sierra Madre Club at 6:30 p. m., September 29, the price being $2 per plate. Members are requested to reserve places for themselves and guests by sending word to S. W. Mudd, 1101 Central building, Los Angeles, before September 28. Through the courtesy of the engineers of the Los Angeles aqueduct an excursion to two divisions of that great work has also been arranged, occupying October 1 and 2. The party will leave Los Angeles Friday evening, September 30, on 'The Owl' train of the Southern Pacific, and will stop at the Fred Harvey hotel at Mojave that and the succeeding night. Autos will be provided for the excursion Saturday over the Jawbone division to the north, and Sunday for inspection of interesting tunnel work to the south. A session of the members will be held at the hotel Saturday evening, and from Mojave visiting members can return to Los Angeles or go directly north or east Sunday evening, as may be most convenient. It is impossible to give an exact estimate of the total expense of the trip, though it will probably not exceed $25 per person. Owing to limited accommodations at Mojave it is necessary that members expecting to take part in the excursion signify their purpose to do so by a note to Mr. Mudd, on or before September 26. In making arrangements preference will be given to members, but to the extent that accommodations can be secured, guests will also be welcome. At some convenient time at Los Angeles or Mojave an executive session of the members present is proposed to consider the work of the Society.

COMMERCIAL PARAGRAPHS

The HENDRYX CYANIDE MACHINERY Co. has moved its office and exhibit room from Denver, Colorado, to 107-109 William street, New York City.

The WOOD DRILL WORKS, Paterson, New Jersey, has been awarded a contract by the Isthmian Canal Commission for 2100 'Wood' brand hose couplings.

JAMES H. PERSHING, FREDERICK S. TITSWORTH, and WILLIAM R. KING have established the law firm of Pershing & Titsworth, at 404 Equitable building, Denver, Colorado.

COX & JUESSEN have established offices in the Sheldon building, San Francisco, and will hereafter devote some time to examination work as well as management.

THE MINE & SMELTER SUPPLY Co. announces the appointment of T. Evans, formerly purchasing agent for The Cananea Consolidated Copper Co., as local manager of its branch house in Denver, Colorado.

THE C. O. BARTLETT & SNOW Co., Cleveland, Ohio, has leased the property recently vacated by the McMyler Mfg. Co., and will install a large amount of additional machinery, thereby greatly increasing the capacity of its own plant.

Sylvester S. Howell has become associated with Paul M. Chamberlain, engineer, Marquette building, Chicago, under the firm name of CHAMBERLAIN & HOWELL. The firm will carry on the general designing and consulting practice established by Mr. Chamberlain.

Bert. M. Meadows, for several years connected with the Charlotte Supply Co., of Birmingham, Alabama, has joined the selling force of the J. GEO. LEYNER ENGINEERING WORKS Co., assisting its Birmingham representative, K. B. Stephens, in handling the drill and drill sharpener business in the Southeastern States.

THE KILBOURNE & JACOBS MFG. Co., Columbus, Ohio, advises that it has recently received an order for 500 cars from the Illinois Tunnel Co. for use in conveying freight under the streets of Chicago. The cars are to be small double-truck gondolas of all steel construction with a capacity of 15,000 pounds.

The LANE SLOW SPEED CHILIAN MILL Co., Los Angeles, advises that it has recently made sales of Lane mills to the following: Bonnie Doone mine, Indian Trail, N. C.; National Mining Co., National, Nev.; Cia. Minera Garduna y Anexas, Placeres de Oro, Mexico; Isabelle Mines, Casa Grande, Ariz.; Stafford mine, Vicksburg, Arizona.

THE HAMPSON-FIELDING ENGINEERING Co., Denver, is moving into its new quarters at 1713 Wazee street, on 'Machinery Row.' A great advantage in this location will be the standard-gauge track at the rear of the store. The Hampson-Fielding Engineering Co. has secured the account of the Edgar Allen Co. and carries a full stock of its steel for mining and other purposes.

C. F. BUCK, who has been with the American Smelting & Refining Co. for a number of years as designing and constructing engineer, has recently opened an office as consulting engineer at 416 Newhouse building, Salt Lake, Utah. Mr. Buck has had wide experience in the design and construction of both lead and copper smelters as well as mining and power plants.

J. B. MCINTOSH, lately engineer in charge of the new Tooele plant of the International S. & R. Co., has resigned to become superintendent of construction for the A. S. & R. Co. at the Garfield plant. E. E. THUM, lately chief civil engineer for the Tooele plant, has been transferred to the position of engineer for the Boston & Montana Reduction Works, of the Anaconda Copper Mining Company.

The FOOS GAS ENGINE Co., Springfield, Ohio, is preparing plans for a new building necessary to double the output. For the last ten months the factory has worked a double shift. In spite of all the extra working time the salesroom has been loafing along way ahead of the increased output with orders piling up for special hoisting equipment. The splendid organization with which this factory is operated will soon have orders well under control.

TABLE OF CONTENTS

EDITORIAL

OUR article on 'Australia's Premier Tin Mine,' published June 4, was, it seems, based on material originally collected for *The Argus*, published at Melbourne: a fact but recently called to our attention. We hasten to make acknowledgments and regret that an unintentional discourtesy has been shown to that enterprising newspaper.

PEAVINE, a small peak near Reno, Nevada, that was represented last week as having become an active volcano, proved on exploration to be a tilted fault block consisting of granite, diorite, andesite, and some Mesozoic schists. The painstaking investigator who climbed to the top reports that the only smoke apparent was from distant forest fires.

BROMINE, while widely applied to the treatment of Australian gold ores, has not been extensively used in America. For that reason the details as to treatment and results at the Black Oak mine in California in 1905 are of interest. They are given in our Discussion department this week by Mr. Murray N. Colman, who was chemist in charge at the time the work was done.

RESUMPTION of sinking in the deep vertical shaft of the Kennedy mine at Jackson, California, will further strengthen faith in the possibilities of deep mining on the Mother Lode. The shaft has passed the 3500-foot mark and is going down at the rate of about 90 feet monthly. The deepest level at present is at 3300 feet, where there are well developed veins of profitable ore.

PANAMA Canal excavation during July totaled 2,406,288 cubic yards, for the second time this year dropping below the 100,000 cubic yard daily average, with an average of 96,252 cubic yards for each of the 25 working days. The rainfall for the month was 15.65 inches. The amount of concrete laid during July was 131,653 cubic yards, against 124,214 in June, and 654,095 of fill was placed in dams, against 664,155 cubic yards in the previous month.

MUCH has been contributed at various times to the gaiety of the Nation by Mr. F. Augustus Heinze, and much it is reputed, to disquiet at 26 Broadway. His has been a stormy career, and even his honeymoon is being disturbed by tales of a 'Titian haired siren.' It is well to remember that Mr. Heinze has at least some good constructive work to his credit and to his faith and foresight is due the Ohio Copper Company, whose mill is discribed on another page by Mr. Leroy A. Palmer. Associated with Mr.

Heinze in the project are a number of excellent and capable men, and long after he and his personal troubles are forgotten, the world will be the richer for the enterprise.

HEAVY monolithic structures, comprising mortar-block, battery posts, and the necessary beams usual in such construction, are now advised by Mr. G. A. Robertson at Johannesburg, South Africa. He suggests that the entire structure can be made of reinforced concrete, which would be fire-proof, without joints, and in every way more durable, and better able to resist the tremendous vibration of heavy stamps, than wood alone, or composite structures of both wood and concrete.

PRACTICAL WORK in surveying involves many short cuts and 'tricks of the trade' that do not get into text-books. We are glad to present an account of some of them written by Mr. A. E. Robinson, who has had large experience in the Coeur d'Alene district. Not everyone will agree with all his methods, but all may take to heart his shrewd observation that accurate results depend more on the care with which a method is applied than on the method itself. This applies to more things than surveying.

THE AUGUST number of *The Mining Magazine* is, as usual, full of things well worth reading. It marks the end of the first year of publication of this highly useful periodical. An international review of mining had long been needed as has been proved by the success attending Mr. Rickard's London enterprise. The road of the pioneer is easy now as compared with that traveled by the *Mining and Scientific Press* fifty years ago, but pluck and skill evidently count near London Wall as they did in the City of the Golden Gate.

REPORTS from the tin mines of the Black Hills of South Dakota are encouraging. In two districts, one in the Harney Peak region, the other at Nigger Hill, attempts have been made for several years to place the production of tin on a commercial basis but up to the present year these efforts have seemingly fallen a little short of success. That the granite dikes carry cassiterite is well known, but the metallurgical problem is serious and it has been the stumbling block in the road to success. The ores differ from those of other tin-producing districts of the world, and, in fact, among themselves. Difficulties in the way of successful concentration have thus far baffled the serious efforts and expensive experiments of the Black Hills operators. Perhaps it is more a problem of economics than of mechanics that must be solved.

FOREST fires, while not so serious as last week, continue to burn in many parts of the West. In a recent interview Mr. Gifford Pinchot has pointed out that with a larger force of rangers, with paths through the forests, and with more telephone lines, much if not all of the damage could have been avoided, since the fires would have been extinguished before they got beyond control. Certainly it is ridiculous to attempt to protect over 200,000,000 acres of woodland with less than 3000 men. In some cases a single man has been responsible for protecting more than 100,000 acres. In other cases there were no trails whereby men could make their way to the danger points and in every way the fire-fighters were hampered by inadequate preparation. A heavy responsibility rests on Mr. W. B. Heyburn, Mr. Thomas H. Carter, and Mr. F. W. Mondell, who have done so much in Congress to cripple the Forest Service.

CRIPPLE CREEK is anticipating a boom. Within a few days the deep drainage tunnel has begun to draw water from the mineral-bearing ground. According to the determination of Messrs. Lindgren and Ransome of the U. S. Geological Survey the ores long worked at Cripple Creek are primary. There exists therefore no reason to anticipate increasing poverty within minable depth, except as the rocks because of being less fractured may not have permitted formation of as large ore-shoots. In the opinion of keen observers the lower levels now open show much less fracturing than above, as is well in accord with common principles. Still lower ground may be even less fractured. Granting this, however, there is none the less every reason to anticipate the finding of much good ore and this will doubtless stimulate further development in many mines now closed. On the whole the pleasant hopes of operators at Cripple Creek rest on solid foundation.

ZINC has been the bugbear of Western ore producers so long that it is difficult for them to learn to look on it as an asset. The analysis of present conditions in the zinc-smelting industry presented this week by Mr. R. G. Hall, the accomplished general manager of the United Zinc & Chemical Company, indicates that Western miners would do well to look after the zincblende now being wasted. Zinc smelting has long been the most backward of the great smelting industries because of the peculiar metallurgical difficulties involved in reducing this most volatile of metals. Improvements in the last fifteen years have been numerous and results now regularly obtained are marvelous when compared with those in the small coal-burning Belgian furnaces, treating hand-roasted ore, that dotted the prairies of eastern Kansas in the nineties. In recent improvements in zinc smelting American metallurgists have had a large and honorable part, quite making up for the earlier years of neglect of the industry.

STANDARDIZATION of mining and metallurgical terms seems to be making progress. The sub-Committee of the Chemical, Metallurgical, and Mining Society of South Africa, has presented a brief but excellent report embodying provisional recommendations, among which we recognize many for which the *Mining and Scientific Press* has consistently argued. Except when otherwise necessary such words as sand, tailing, and slime, are to be treated as collective nouns and therefore used in the singu-

lar; abbreviations such as oz., lb., gal., are not to be printed in the plural; 'shoot' is restricted to geological usage, while 'chute' is to be used to describe a passage or opening through which material is guided; in referring to screens, whether the number of holes refers to the square or linear inch should be stated; the 2000-lb. ton is to be used, and various other precautions are to be taken to prevent confusion. It is easy to go to extremes in reforming so illogical a thing as language, but the need of greater uniformity is so great that efforts in this direction will be welcomed by all workers in technology.

Mr. Roosevelt and the Insurgents

Osawatomie is a small city in eastern Kansas, known as the scene of conflict between Mr. John Brown and his followers and certain upholders of slavery in the troublesome days of 1856. It is a prosperous centre of a rich farming community, but its people have ever been alert as regards anything touching on freedom. It was peculiarly appropriate that Mr. Theodore Roosevelt should journey to that point to make his long anticipated profession of political faith and the speech that he made on the last day of August, is vibrant with the characteristic feeling of the community. Read in the light of his earlier speeches and his whole career, it is exactly what would have been expected. There is the same plea for the average man, the same demand for equality of opportunity, the same criticism of the corrupt rich and vicious poor, the same exhortation to progress. No one who has studied Mr. Roosevelt has doubted that his heart was with the Insurgents in his party. Their opposition to special interests is the essence of his own political creed. The significance is not in that he believes with them but that he openly sides against the leaders of his party. Mr. Roosevelt is probably the keenest politician in America. He knows and values public opinion as does no one else. He is undoubtedly the most widely popular man in the country and he counts on that popularity as a means to his ends. As a prudent fighter he chooses well the time and season for each public act and that he should now throw his influence openly with the 'Progressives', as he prefers to call them, means that the best reader of public opinion in this country sees victory for them. No wonder Wall Street is disturbed, for Wall street, like big business everywhere, does not so much dread reform as change. The men who know the game as it is now played, who can win under present rules, naturally fear any proposal for change. To mining men the most significant point in Mr. Roosevelt's recent speeches is his unequivocal advocacy of a leasing system for mineral lands. That old abuses must be corrected is now everywhere conceded, but whether the change should take the form of introducing leasing, is a matter about which there is no agreement. Mining men, as the ones most interested, should inform themselves and formulate their program; and in doing so they should, like Mr. Roosevelt, take careful account of public opinion throughout the country.

English Estimates of Peruvian Copper

Ferrobamba Limited has been up for renewed discussion in London. Mr. Claude Vautin has returned from his examination of the property and confirms in the strongest manner the estimates of Mr. W. E. Gordon Firebrace as to the amount of copper-bearing rock in this new Peruvian mine. At the Ferrobamba No. 1, some 27,635,700 cubic yards of material are calculated to be available by open-cut workings with enormous amounts to be won with each additional foot of depth. "As to the percentage of copper this mass of ore is likely to contain, it is, of course, not possible at the present stage of operation to tell," remarked Mr. Vautin at the meeting of the shareholders held in London August 4, after which conservative statement results of incomplete sampling were quoted that showed 6 per cent copper with 9 grains gold and 3 ounces silver, and it was pointedly implied that the bulk of the material is at least of approximately this grade. We must confess our sympathies are with the anxious stockholder who asked "Whether, in addition to the enormous deposits of copper which this company owns, there are other deposits of like nature, because if so, and they are of anything like the same extent that these run to, and can be operated on anything like the same colossal scale, it will possibly bring down the price of copper to such a level as to have a very serious effect." It is quite comforting to have the assurance of the chairman that "so far as we know, there are no other deposits of the same character anywhere near ours, and the man from whom the properties were purchased, Mr. Hilfiker, spent five or six years looking for other deposits and was unable to find any."

This matter then being so satisfactorily and completely disposed of, it may be well to consider a moment the matter of uniformity of distribution of copper through the great garnet mass that evidently exists along the contact of the hornblende biotite granite and limestone. There is no reason to doubt the accuracy of the calculations to the amount of garnet rock present but the amount of sampling yet done, so far as there is any published statement, utterly fails to warrant the inference that the whole or the major part of it contains 6 per cent of copper. Such a conclusion is furthermore contrary to experience elsewhere, and particularly with the great porphyry coppers of the United States, where more has been done than elsewhere and a better basis exists for forming an opinion. Mr. Vautin affirms his unhesitating belief "that the copper values are uniformly disseminated through the garnet rock;" which is entitled to respectful consideration as a belief. It is fair, however, to point out that Mr. Vautin is better known as a metallurgist than as a geologist and the need of further examinations and of caution may be properly urged. Without much doubt the Ferrobamba is an important copper property, certainly Peru does contain enormous ore deposits and vast potential mineral wealth, but before throwing aside all previous standards of measurement we shall await the results of drilling now being begun.

Details of Mine Surveying

By A. E. Robinson

Many textbooks, and some technical schools, give instruction in surveying. Few of either go deep enough into the subject to be practical, confining their teaching to generalizations, giving many methods, but not specifying which is to be used under given conditions; explaining the manipulation of the instruments used, but giving no directions for intelligently recording the operations performed. Consequently few technical graduates are competent to make a survey; they must first take a post-graduate course under some practising engineer before they can perform the few, simple, and almost mechanical, operations that go to make a survey. It is hoped that this class of men in particular will find something of benefit in the following, as these notes give an abstract of the instructions I have found necessary to give to graduates. As stated, it is a simple proceeding to make a traverse survey; there is nothing complicated nor involved in it, yet, by doing it carefully and conscientiously it is possible to achieve accuracy that is as beneficial to employer as it is pleasing to the surveyor.

The following are some of the methods employed by myself recently in conducting a survey in which over 13,000 transit points were used and 143 miles of surface and underground traverses run. To many, and particularly the experienced engineer, there may seem to be an unwarranted refinement in these methods, yet in this particular work the pains taken were justified by the results. The purpose for which a survey is made and the time at the engineer's disposal will govern the amount of extra precaution he will take to insure accuracy. The greatest error in this survey was 1 in 4500, the smallest 1 in 13,000, with an average of 1 in about 6500. Credit is due to R. J. White, chief engineer of the Federal M. & S. Co., Wallace, Idaho, and to Edw. C. Uren, engineer, Nevada City, California, for many valuable suggestions.

Perhaps the most severe test to which a survey and map may be put is in litigation; an engineer may bluff a foreman into believing that a raise did not 'hole through' into a drift at the desired point because the miners did not follow his line, but an error in a map, that ordinarily would be of small consequence, would, in a court room, under the scrutiny of the engineers of the opposing side, be speedily brought to notice of the court, and would cast a strong shadow of doubt over the entire map, and on all testimony given in which reference was made to the map. Acquire the habit of accuracy, therefore, by always working to obtain the greatest exactness, and you will never get caught with inaccurate maps. The presumption that work is accurate depends upon the care exercised in its performance and the methods employed. This presumption, in surveying, amounts to proof in the case of a traverse that either closes on itself, or on some point whose position is known. In a 'blind' traverse—one not connected at both ends with known points—where there is no opportunity to check the correctness of the work, dependence must be placed entirely on the two factors stated. The first, care, is an entirely personal one. It is a moot question among engineers as to which methods are best. Some engineers get good results with methods that to another would be difficult, unsatisfactory, and confusing. I never knew an engineer who did good work who did not ascribe his success to the methods he used rather than to the care with which he employed his own methods, and yet it was to the latter that most of the credit was due. He was able to distinguish between the good and the bad in his system, and yet it may not have been the best. Good practice may be defined as that which invariably gives results as near the absolute as is possible with the instruments used by any instrument man. Consequently for a method to be the best, it must give equal accuracy under all conditions. The best method for making this survey was decided upon after comparing the advantages and disadvantages of all methods and adopting that which possessed a maximum of advantages, a minimum of disadvantages, and which afforded a complete check on itself.

To eliminate the errors due to human failings, as well as those due to imperfections in instruments, the same resultant should be obtained by two different methods. A man may read a deflection angle between two courses; it would not be a check on his work if he re-read the same angle in the same manner as at first. He might make the same personal error in reading, or either the horizontal axis or line of collimation might be out of adjustment, and while the angle read in both instances would be identical, it would still be incorrect. Therefore, in performing an operation for the purpose of checking any other operation, do it so it will check beyond doubt. This applies to work in the office as well as in the field, and he is the best engineer who invariably checks his every move. In the field do not only check your work to your own satisfaction at the time, but record it in your notes, that each setup may, if necessary, be checked in the office. This is particularly necessary in the survey of workings that are being used in the operation of the mine. A rapid lateral motion accompanied by a frantic grabbing of the instrument (never call it a 'machine'), to avoid contact with a loaded car on a down-grade, has been known to affect a transitman's nerves to the extent of rendering doubtful the notes taken for several hours thereafter.

Traverses are run in mine surveys for the purpose of fixing in the three planes of projection certain points in the mine, and on the surface above. From these points the contour of the surface, and of underground workings, and the position of other points, corners of claims, and other data, are ascertained. The transit is the instrument used. In all work around a mine, the light transits, weighing about 14 lb., give as good results as the larger instruments, and are to be preferred on account of the greater ease with which they can be set up in 'tight' places and from the fact that they are much easier to carry.

In surface surveying, the points are usually 6-

penny finishing nails partly driven into the tops of hubs extending from 2 to 3 ft. above the ground. Underground, the points used vary, and there is little choice, providing the point be one cheaply and easily made, which will not rust and drop out, and from which a plumb-bob will always hang in the same position. The necessity for the last will be appreciated when it is remembered that in making a traverse the point is used three times—by the foresight and backsight bobs, and by the transit bob. I prefer a horseshoe nail having its head flattened, and with either a fine saw-cut made in the edge, or a hole not exceeding $^3/_{32}$ in. diam. punched in the lower edge. Six-penny finishing nails bent to a U make satisfactory temporary points, are quickly made, but they soon rust and must always have a plug driven in the 'back' to receive them, as it is generally impossible to find a crack in the rock overhead at the right place into which they can be driven. Horseshoe nails can be driven into a small crack, and being made of soft iron, do not rust quickly.

To run a traverse of underground workings, the transit is set up under the last point set; by 'under', I mean under specifically, and not generally. The best bob to be obtained should be used in this work. I have found it to be expeditious to use a small hook on the upper end of the plumb-bob string; this is hooked into the transit point overhead, and the bob raised, or lowered, to the right elevation by means of an adaptation of the old, familiar, pants-button slide. A doubled string, or piece of fine copper wire, is run through the top of the bob, leaving a loop at the top; one end of the bob-string is fastened to the hook, and the other end threaded through two holes in the button, then through the loop and back to the button, to which it is tied. By using the slide arranged in this manner, the bob can be manipulated with one hand. The back and foresight bobs are then hung on their respective points, the plate set, and the first operation, that of getting the foresight course, commenced.

Courses are carried by several different methods most of them good when care in using them is practicable, but few methods, when used alone, are adaptable to all conditions. The courses may be carried direct on the plate, referred to either the north or south point alone. This is known as carrying azimuths. In working with this method, when the transit is set-up ready for work, the line through 0° and 180° will coincide with the meridian, with the 0° usually to the south. The last-read azimuth is set off on the plate, the telescope directed to the backsight and clamped. The upper limb is then unclamped, the telescope transited or revolved on the vertical axis and directed to the foresight, and the azimuth of the foresight-course read. All of the courses in the northeast and northwest quadrants (and in one of the south quadrants also, if the azimuth be read in but one direction), must be calculated. It has the advantage that all courses are expressed simply, in terms of degrees and minutes in the field notes. The course may be carried on the plate, referred to the meridian, and having the quadrant in which the course occurs stated. There are a number of advantages in this: the course is always known in the field without calculation, and is stated in the same terms in the notes as will always be employed for that course thereafter; the office work is simplified, and that makes for accuracy and economy. The disadvantages are: liability to reading a wrong course when it is nearly east-west or north-south—N.89°W. may be read S.89°W.; liability to reading the course in the wrong quadrant—a northwest course may be read southeast, if the transitman is in unfamiliar workings, or gets 'turned around'; errors of 1, 5, or even 10 degrees can thus easily be made. Perhaps the most serious objection to using either of the above methods lies in the necessity of re-running a traverse if an error has been made, there being absolutely no other way of determining the point at which the error was made.

Deflection angles may be read. This method is simple inasmuch as the vernier is set at 0° on the backsight; it halves the error of reading, for the vernier on any instrument not having a micrometer attachment, can be set at some even degree closer than it can be read when set at random. The angle can be checked by doubling. The use of deflection angles, however, involves calculation of courses in the office, thereby introducing extra work and liability to error, which liability is greatly increased when the office work is done by men unfamiliar with field conditions.

To check any horizontal angle, it should be read once with the telescope direct and once with it reversed. This eliminates errors of collimation, and in taking inclined sights is a partial check on the horizontal axis as well. It is possible for both axes to be out of adjustment, and the errors to apparently compensate for a certain inclination of the line of sight. When reading a deflection angle, and doubling it as a check, a third reading is necessary, with the telescope reversed, to check the collimation. This need not be done at every station, yet transits sometimes have the very disagreeable habit of getting out of adjustment without apparent provocation and without warning, and especially in small working places and on a rough surface where it is not always possible to avoid jars. It is a good thing to know the fineness of the adjustment of the transit at all times.

A combination of carrying the course on the plate and reading deflection angles has been found to be most satisfactory. The course is read, and checked by a deflection; this gives all of the advantages of using both methods alone, eliminates all the undesirable features of using either separately, and requires no more time in the field than any other method. After the deflection angle has been read (with the telescope pointing opposite to its position when the course was read), the course is calculated. If this does not agree with the first reading, the reason must be found and the correct course determined before proceeding further. If the line of collimation be in correct adjustment and the work has been carefully performed, it is probable that the difference is due to the fact that few lines in the field

make an angle of some even minute with any other line. The deflection angle can be doubled to ascertain if this be the cause. In many cases this is an unnecessary refinement, and would be used only when extreme accuracy was important. When the difference is small—not exceeding half a minute—this difference is the sum of all the natural errors, namely, those due to the personal equation, to imperfect adjustment, and to that portion of the angle that is too small to be read. Errors of half a minute will generally balance in a traverse of considerable length. To eliminate the errors due to lack of fine adjustment, read the courses at all even-numbered set-ups with the telescope direct, and at all odd-numbered set-ups with it reversed.

The advantages of reading a course and checking it with a deflection angle are: as perfect a check as can be had on the manipulations of the transit; the courses are known in the field, and are ready for the office men without calculation; if by any chance an error is made in the field work that is not detected until the notes are computed or platted, it can, in most cases, be found by referring to the notes, and without re-running the traverse. As a matter of fact, it is almost impossible for an error to creep into the survey when this method, or combination of methods, is used, but if an engineer makes one hundred set-ups and has one error, yet will he forsake the ninety and nine good courses and seek the one that gives him the trouble. Another advantage is manifest when in making a survey where it is necessary to start on an assumed or a magnetic course, and afterward 'tieing' into some known course. Assuming the course of the known line to be 30 min. greater in the northwest quadrant than the course of the same line from the assumed meridian, 30 min. must be added to every course in the northwest and southeast quadrants, and be subtracted from every one in the northeast and southwest quadrants. The entire new set of courses can then be checked by the deflection angles. After obtaining the correct course in the field, the telescope is leveled and the foresight bob set at the horizontal wire if the sight be taken in a level working, and the distance from the centre of the horizontal axis of the instrument to the bob measured. Although there are a number of methods of checking the taping, any of which, if they were satisfactory, would be of particular value on the surface, where the measurements are longer than underground and consequently more liable to error, yet there is no scheme I have tried that has proved worth retaining. A distance should always be taped twice, to assure yourself that your assistant has held his end (the so-called 'ignorant end'), at the proper place, if for no other reason. In stretching the tape it is not necessary to attempt to pull your assistant out of his shoes to get a good measurement. For distances up to 200 ft. a pull of 20 lb. is sufficient. For greater distances, measurement 'on the swing' gives closer results. I have proved this, both underground and on the surface, with two tapes, one ¼ in. wide, and the other $^1/_{10}$ in. wide. In the first case the distance was 390 ft. The swing measurements agreed very closely with themselves and with the correct distance as obtained by measuring with the tape supported at intervals. When the taping was done with a steady pull, it was difficult to get any two measurements to agree with each other, and the tape indicated from 0.10 to 0.30 ft. greater than the actual distance. On the surface the distance was 645 ft. This was checked by a traverse between the hubs. The variation in measurements made with a steady pull was nearly as great in proportion as in the underground measurements; the swing distance and the traverse checked by 0.03 ft. In both cases both sets of measurements were made by two transitmen, separately, to make sure that the difference was due to the manner of taping only.

To get the swing, pull the tape fairly tight to get a handhold at the proper place, let it slacken slightly, and pull up the slack with a steady and fairly rapid pull. The centre of the tape will swing up until the entire tape is in an almost straight line; before it drops back, mark with the thumbnail the point on the tape opposite the centre of the horizontal axis, and pull the tape up again to check the position of the mark. Distances can be measured more accurately underground than on the surface and owing to the short sights underground, courses on the surface are the more nearly correct. Underground, the taping is always done from the instrument to the bob.

FORM OF FIELD NOTES

Def. 1.	Sta.	Vert. ang.	Slope dist.	Course.	Hor. dist.	To
	38		backsight	S.8°28′E.		39
L 00°02′	39	—44°32′	108.75 ft.	S.8°30′E.		40
L 22°05′	40			S.30°35′E.	21.49 ft.	41

This varies from the forms generally used. The deflection angle is placed on the extreme left to keep it out of the way of the rest of the notes—having performed its function of checking the course it is of no further immediate use, but is recorded for future reference. 'Sta.' indicates the station at which the set-up was made. The course is sandwiched between the slope distance and the horizontal distance to simplify office work; as in platting the eye has to follow the two columns of 'course' and 'distance' only, and they are therefore placed together, and in the order in which the platting is done.

Elevations obtained with the transit are generally sufficiently accurate for the underground and surface work done in connection with mining. The elevations in closed traverses will be found to check closer than the latitudes and departures. To adjust the horizontal wire and vertical circle of a transit, when a Wye level is to be had, set up the level and transit so that a line connecting the centres of both eye-pieces will be level when the telescopes are horizontal. Sight at some distant object through the level, then direct the transit toward the same object, and, by moving the tangent screw on the clamp of the horizontal axis, bring the horizontal wire of the transit on the same object. Then, with an adjusting pin, bring the bubble of the telescope level to the centre of the tube; loosen the vernier of the vertical circle and set it at zero. Like all adjustments, this requires patience, but it is simpler and quicker than the 'peg adjustment'.

Elevations are obtained in surfaee surveying as follows. The height of the centre of the horizontal axis above the transit point is measured and recorded. This is the H. I. The vertieal angle to the foresight point is then read and recorded with its proper sign prefixed minus (—), if an angle of depression, and plus (+), if an angle of aseension. The slope distanee multiplied by the eosine and sine of the vertical angle gives the horizontal and vertieal distanees respectively, from the centre of the horizontal axis to the foresight. If the vertical angle is minus, the H. I. is subtraeted from, and if plus, is added to, the vertical distance to get the net vertical, namely, the difference in elevation between the two points. To eheek this, read the verticle angle to the backsight when set up over the point to whieh the sight was first taken. The tangent of this angle multiplied by the horizontal distanee gives the vertical eomponent, and the net vertieal is obtained by substraeting the H. I. of the new set-up from this vertieal distanee if the angle to the baeksight be one of depression, and by adding, if it be one of aseension.

The first H. I., 2.13 ft. is the H. I. at Sta. 4, and the bob, 3.13 ft., the bob-height for the same sight at Sta. 5. On the second line is the bob-height at Sta. 4 (2.85 ft.) when it was sighted from a set-up 3.85 ft. below Sta. 5. The net verticals of the two sights can be quiekly figured in the field. Where a vertical angle is read, the notes are reeorded as directed for surface work, with the 'bob' additional. Where there is a difference of a few hundredths between the two net verticals, their average may be used without introducing a serious error. Failure to agree may be due to laek of adjustment or a mistake made in taking or recording any of the angles or distanees. It generally saves work to try to determine where the error lies. If the trouble lies in the transit, none of the net verticals in a day's work will agree. A mistake made in either the vertieal angle or the bob-heights will appear at only one plaee, and the only thing to be done is to make a new set-up at either station. This will probably eheek with one of the net verticals obtained before. The same differenee between two eonsecutive sets of net vertieals is due to the H. I. at the middle station being wrong. If this difference be added algebraieally to the H. I. in the notes, it will give the correct H. I. All additions to or alterations made in notes should be done with red ink, and the original note erossed out, but not obliterated. As the error made in taping is usually some even foot or tenth of a foot, a slope distanee may be found by trial, which, when used with the angles, in the notes, will give equal net vertieals. A measurement should then be made. The elevation of the floor or rail is taken at intervals by measuring from the transit point, and is recorded in the notes as a minus net vertieal from the point.

FORM OF FIELD NOTES

Sta.	H. I.	Vert. ang.	Slope.	Course.	Hor. dist.	To	Bob.	Vert.	Net Vert.
933	+ 2.18	— 17°47′	135 ft.	....	128.55 ft.	934	0.00	— 41.23	— 39.03
933	0.00	— 15°57′				934	+ 2.28	— 36.74	— 39.02

The underseored figures are the results of eomputations made generally in the office. On the first line is the H. I. at Sta. 933, then the minus vertieal angle; under the 'bob' column is 0.00, indieating that the transit point itself was sighted. On the second line is the baeksight reading from 934 to 933, but instead of being recorded as actually taken, is given as if taken from 0.00 set-up at 933 to a point 2.28 ft. above 934. This would be identieal with the angle read from a set-up 2.28 ft. above 934 to the point at 933. The purpose of this is to have the sines of both net verticals the same to prevent errors in figuring the elevations, and to save spaee in the notes. The two net vertieals should agree very elosely.

Elevations are earried underground, (1) by using the transit as a Wye level. (2) by reading vertical angles. The second method is identieal with the first when the vertical angle is 00°00′. To earry a line of levels underground with the transit, the telescope is leveled and pointed to the plumb-bob hung on the point ahead, and the assistant raises or lowers the bob until some definite point on it, usually the top, is interseeted by the horizontal wire. A simple eode of signals, similar to the signals given in Wye leveling, but made with a light, is used. The H. I. of the transit, which in this work is its distanee below the point, and has a minus sign, and the distanee of the bob below its point, the 'bob', are measured. The net vertical is the differenee between the two. This can be eheeked by 'setting' the bob at the baeksight station and measuring its height. As before, the notes will read as if both sights were made from one station, namely:

Sta.	H. I.	To.	Bob.	Net vert.
4	— 2.13 ft.	5	— 3.13 ft.	+ 1.00
4	— 2.85 ft.	5	— 3.85 ft.	+ 1.00

As before stated, the objeet of a survey is not alone to fix the locus of certain points, but to note suffieient other data that the outlines of the workings may be platted, and accurate sections made. In seleeting a system of taking deseriptive notes, choose one that will be eoneise and complete; there should be no ambiguity, and the notes should be such that only one interpretation is possible. Sketehes made to the same seale as the working map are highly desirable, in faet indispensable in any but the simplest workings. On the sketeh there should be a suffieient number of points loeated by transit, or 'side-shots', to eontrol the sketch, and fix the position of the most important changes in eontour. Side notes are offsets taken from different points along the line of traverse to the sides of drifts, lips of chutes, or to other points. They are taken after the measurement to the foresight has been made, when the transitman walks along the tape, and at any change in the eontour, makes a note of the distanee from the set-up, and the offsets to the sides at right angles to the tape. Sueh notes are recorded as 'mixed numbers', the whole number being the dis-

tance from the transit, the numerator the offset to the right, and the denominator that to the left. To make correct sections it is sometimes necessary to take notes to the 'back' and bottom of workings. 'Top and bottom' notes are taken for this, and are recorded as fractions, the numerator being the distance to the back and the denominator that to the bottom. To distinguish them from side notes, they are enclosed in a circle. Unless the contour be a flat curve, side notes should not be taken if the offset is greater than 10 ft., but a 'shot' should be taken with the transit to locate the contour.

The first work to be done on a set of notes on their receipt in the office, is to make the necessary calculations. All slope distances are resolved into their horizontal and vertical components, the latitude, departure, and elevation of each point figured, and the co-ordinates obtained by adding algebraically the latitude and departure of any course to the co-ordinates of the station at the beginning of the course. To avoid errors in these calculations, either one man must make them by two different methods, or two men work separately and check each other. It makes little difference which tables be used, whether they be of logarithmic or natural functions—it depends on the preference of the computer. Any good mechanical computer saves a great amount of time, and where there is much of this work to be done, will soon repay its first cost. An office record should be kept. This should show the course and distance between points, net vertical latitudes, and departures, co-ordinates, with a few brief remarks when necessary.

Platting notes direct from the field book or sheets by means of a steel T-square, protractor, and scale, is by far the most rapid method. The position of every fifth point should then be checked by its co-ordinates, and should agree within a foot on a map made to a 50-ft. scale. This is a check on both the platting and the computing. A protractor should be used that is correct to 5 minutes. My preference is for the Browne & Sharpe protractor, reading to 5 minutes on the vernier. It can be set to 2 minutes by interpolation. After a number of points have been platted, and their positions checked, the sides of drifts, and other data, are platted from the side notes, and inked in. The transit points are represented by small circles, with the number of each shown in black, and its elevation shown in red under the number of the point.

Workings not in a horizontal, or nearly horizontal, plane are distinguished by conventional signs, of which there is a multitude. It is to be regretted that there is not more uniformity in this. An opening below a level is shown by shading the upper left hand corner, simulating the shadow thrown by an imaginary underground sun. If the opening be above the level, the opposite corner may be shaded, if it be a raise or major opening. Manways are indicated by a rectangle at the foot, with one diagonal line. If a winze, or shaft, passes through a level, that fact is shown by dividing each compartment with two diagonal lines and inking in the portion below and above their intersection. A solid black rectangle represents the lip of a chute. An incline of any kind may be distinguished by hatching, parallel to the sides, or by short hatching, from the sides, pointing down the incline, and roughly representing the flow of ore or waste. If there be more than one compartment, the manway side is usually left open. Stopes are best platted by showing contours at given vertical intervals, except in a simple fissure vein, when a longitudinal vertical section parallel to the strike is generally sufficient. If square sets are used, the platting is simple—only the sets being shown. Otherwise contours have to be worked up in the same manner as surface contours, by interpolating between points on the walls whose elevations are known. When possible, it is well to plat each floor or contour on a separate sheet of tracing cloth, cut

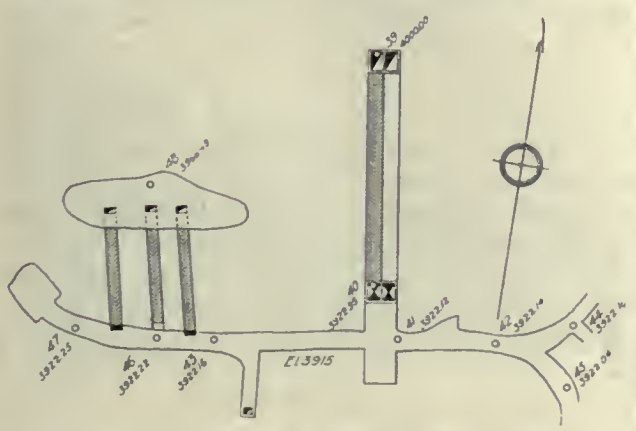
to some convenient size and having co-ordinate lines. On each sheet should be stated the elevation of the contour, or of the cap of the sets. It requires no more time to keep a set of individual floor sheets platted, and by using them, the composite map of the mine need not be disfigured by monthly progress work—only the extreme boundaries of the stopes would be shown on it.

The accompanying notes show how the different work in the field is recorded, and give specimen side notes, from which the map was made. This is a map of workings in a vein dipping to the south, and entered through a winze or shaft. Between 41 and 42, 20 ft. from 41, is a jog on the left (the terms right and left always mean when looking in the same direction that the traverse was run). To avoid error in platting, when there are two notes on the same side of the line, the rule is to join the first note with the last preceding note, and the second with the next note. Between 41 and 43 is a small cross-cut, which is located by a needle course from a point on the traverse line. In some cases this would be slipshod, but is permissible for short cross-cuts. Prefixed to some of the deflection angles



are the letters 'FS'. This means that the deflection angle was turned without having transited the telescope.

There are a great many advantages in using loose-leaves for transit notes. In fact, after having once used them, a book seems crude in comparison. In making an extended survey, the computers and draughtsmen can use the notes of one day's work the next day, if necessary. They are more easily kept clean, for they can collect but one day's accumulation of mud at the most; consequently they are always as legible as when taken. They are more easily platted, as the sheet being used is the only one necessary to keep on the drawing table, and, unlike a book, does not have to be kept open at the right page with a weight. If they get wet, there is no leather cover to warp when dried. They may be ruled on sheets large enough so that all the notes of a 'shot' may be put on one or two lines, without making too large a book to be conveniently handled in the field or necessitating special pockets in the transitman's coat. Having all the notes of a course on one line makes for rapidity in platting and calculating, and less liability to mistakes. They can be so filed that the notes of each level, or part of the mine, will be separate from other notes, and any information about that particular place can be quickly found. The sheet on which the notes accompanying this article are written is 6 by 13½ in., ruled on one side as shown, waterproof ink being used. The vertical lines on the left side should be red, the horizontal lines green, and the right side of the page, ruled into spaces to the same scale as the working maps—in this case 50 ft. to the inch. They are carried in the field, folded along the 'Elevation' column, in an aluminum cover such as is used by expressmen to hold bills. By folding them this way, every column that is used in the field is accessible. The sheet in use is kept first in the cover, so the mere opening of the cover gives access to the right page. In the office, they are filed in covers and indexed in any suitable manner.

PRESENT ZINC-SMELTING CONDITIONS

By R. G. Hall

In September of 1907 practically every zinc-smelting plant, old and new, in the United States was operating at full capacity, two smaller plants were building but not yet ready to operate, and other plants were in prospect or in the minds of promoters. The general curtailment accompanying the panic of October and thereafter in that year caused an extensive closing down of plants and the abandonment of all plans for further construction. Notwithstanding this, the production of spelter for that year set a new record for the United States, 249,860 short tons being produced. This indicated a capacity for production in this country, on the ores proportioned as they were at that time, of close to 300,000 tons. The following table shows the capacity and distribution of the plants at that time:

*ZINC-SMELTING PLANTS IN 1907

Name and Location.	Fuel Used.	Furnaces.	Retorts.
Lanyon Zinc Co., Iola, Kansas	Nat. Gas	15	9000
Cockerill Zinc Co., Iola, Kansas	Nat. Gas	7	4376

United States Z. Co., Pueblo, Colo.	Coal	6†	2074

*'The Mineral Industry,' Vol. XVI, p. 899.

†Muffles, figured to the equivalent number of standard round retorts.

An analysis of this table gives the following proportion of smelting capacities, and appended is shown the percentage of metal produced in 1907:

	Capacity, Per cent.	Metal in 1907, Per cent.
Kansas gas smelters	51.0	52.0
Oklahoma gas smelters	9.6	2.0
West Virginia gas smelters	6.3	8.0
Kansas & West Missouri coal smelters	5.4	4.0
Illinois & East Missouri coal smelters	22.0	23.5
New Jersey-Virginia coal smelters	3.5	8.5
Colorado coal smelters	2.2	2.0

These figures of capacity and production are of course somewhat arbitrary but are substantially correct for 1907. Oklahoma production was low as the plants were not all completed and operating in 1907. In 1909 the production of spelter was approximately 267,000 tons, produced in about the following proportions by the various plants:

	Metal in 1909, Per cent.
Kansas gas plants	38.8
Oklahoma gas plants	10.7
Illinois & East Missouri coal plants	31.3
N. J.-Va. & W. Va. coal plants	17.0
Colorado coal plants	2.2
Kansas & West Missouri coal plants	...

At the present time there are in operation in the Kansas gas belt approximately 19,000 retorts equivalent to 40% of the capacity of plants in that district. In the coal fields of Kansas and western Missouri not one furnace is operating. The balance of the country is operating on about the same capacity as 1907 and 1909. Some slight increases in capacity have been made in West Virginia and Oklahoma, but they are recent and are probably not yet operative.

The conditions precedent to this state of affairs, so disastrous as regards Kansas and Missouri, are of course quite plain—shortage, both of gas and of smelting margin. In the Iola district the works are productive to only about 20% of their capacity, and further decreases may confidently be looked for on the approach of cold weather, not alone in the Iola field but over the whole of the Kansas gas belt. Predictions are dangerous in such an uncertain matter as that under discussion, but most people in the business expect that fully 50% of the capacity of the plants now operating in the Kansas gas belt will be shut down by January, or at latest March, and the gradually increasing cost of gas will cause the mieroseopic smelting margin of the remainder to go the way of the Kansas gas fields. The diminishing smelting margin clearly is largely to blame for the present condition and for receiverships for companies representing 40% of the Kansas-Missouri district. Our 'black sheep', the tariff and 'Uncle Joe', have of course a measureable amount of blame to bear, inasmuch as the duty on zinc ore (raw material) was raised from nothing, to a rate equivalent to about 1¼c. per lb. of metal recoverable, while the duty on metal imported as such, was lowered to the same figure of 1¼c. per lb., leaving no protection to the smelter. The ore producers of the Joplin district have not been slow to use the advantage given them, as by their close combination they are able to do, while imports of spelter are constantly threatened.

Prospecting for natural gas becomes daily more expensive, and the profits with which that prospecting could be done are vanishing. Only in the more recent fields of Oklahoma is there enough gas at any point to operate comfortably. In Oklahoma the smelters are drawing gas by contract from fields apparently still in their vigor, but the exhaustion of Kansas gas is driving the companies supplying domestic and other higher priced consumers into that field so that as far as smelting is concerned the Oklahoma supply, too, is within measurable distance of exhaustion.

These views may seem pessimistic, but the facts themselves are sufficient without any predictions to show that on a normal consumption of spelter the production is today too small. Consumption is at present quite below normal as is the consumption of steel products and in fact of practically all common metals. Any resumption in business must find the smelting capacity inadequate to meet the demands and increase of prices would result. Whether an increased demand for spelter will result in an increased number of plants at other points where fuel may be obtained is a question for the future. It must be remembered that in the coalfields east of the Mississippi, which alone seem available for smelting the Western ores, it will be necessary to manufacture sulphuric acid from the roaster gases in order to avoid damage suits. The cost of a plant capable of working under these conditions becomes at the start almost prohibitive except for the strongest financially, while the possibilities of profit are pretty slender on by-product acid in a field already over-supplied; and besides, as shown above, the financial experiences of the past three years have not been such as to invite further investment of capital in this branch of industry.

In the meantime, with no great increase of ore production probable from the Joplin field even at higher figures than now prevail, and with Mexico and British Columbia practically shut out by the tariff, it would seem that the markets of the miner of zinc ore in the West are secure. Western zinc ores notwithstanding their complex character and metallurgical difficulties, are today selling almost on a parity, considering their percentage of metal, with Joplin ores. Many lead and precious-metal mines formerly unprofitable because of the zinc content of the ore are today deriving a large part of their revenue from the sale of the zinc product alone, and properties as far west as western Arizona, Nevada, and Idaho, are shipping zincblende and calamine, both concentrated and crude to the smeltes of Kansas at profit. With the great improvements of recent times in the methods of concentrating the complicated ores of the Rocky Mountain States, and the increasing skill of the zinc smelter in handling the concentrate, it would seem that the prospector has added another mineral to his list and the once despised 'black jack' may be given hereafter a hearty welcome.

The Ohio Concentrator

By Leroy A. Palmer

The concentrator of the Ohio Copper Co. is situated over the mountain from Bingham, Utah, at the town of Lark at the portal of the Mascotte tunnel. The millsite embraces 1480 acres with a sloping hillside, simplifying to some extent the construction of the mill, and a broad flat which allows of ample room for tailing for many years. The plant, which is about half a mile from the tunnel, embraces two buildings, 'the mill,' as it is locally called, and the 'slime plant.' Both buildings have steel frames on concrete piers with a sheathing of heavy corrugated iron. They are lined with building paper over which is a layer of asbestos held in place by poultry netting. This makes the buildings warm, though in winter they are further heated by hot water carried in four-inch pipes. The walls are well supplied with windows, and in the mill are two rows of seven skylights. These are gabled so that the light from above

Main Mill Building.

strikes directly into the mill instead of from the side. The floors are of concrete with false floors of wood for the comfort of the operatives. Wherever possible all line-shafting is so placed that the belts are well out of the way and the motors are on platforms eight or ten feet above the floor. The line-shafting is readily accessible by means of broad runways which are guarded by hand-rails. The machinery piers are of concrete, and, in the cases of the tables and Chilean mill, are built well above the floor so as to allow plenty of room beneath. A railway switch runs in front of the concentrate bins and another for the handling of supplies and repair parts is at the back of the mill. A 24-in. track for push cars runs to the supply track, and by means of this the heavier repair parts are taken into the building to a point where they can be picked up by the cranes and transported to any point. The slime plant is at one side of the mill and sufficiently low to permit of gravity feed. The distance between the two is such that if the capacity of the mill is doubled, as it may be at some future date, the two buildings will adjoin. The mill building is 317 ft. long and 391 ft. deep in the direction of the flow, and the slime plant is 342 ft. long and 115 ft. deep. The buildings are completed, but only one-half of the machinery is installed and in operation. The original design was for a mill of 2250 tons daily capacity. This has been slightly exceeded, as, during a recent month, the one-half in operation put through 1146 tons per day allowing for all shut-downs and delays.

The mill is divided into two units, each of which is further divided into two sections, one complete unit now being in operation. The ore is a finely disseminated chalcocite and chalcopyrite in a gangue of quartzite. It is brought from the mine through the Mascotte tunnnel in trains of 20 five-ton cars over a trestle and dumped into the crude-ore bins, of which there is one with a capacity of 2000 tons to each unit. The ore-bins have steel frames and are constructed of a double thickness of two-inch plank with flat bottoms, the latter being cheaper to build and to maintain than the sloping bottoms. In the front of each bin are six gates, one near the centre feeding direct to the crusher, while the feed from the others is delivered by a 24-in. belt conveyor running from each end.

The ore is mined by the caving system and breaks quite fine so that the first crushing can be made to 1¼ in. This is done in a 16 by 24-in. Blake crusher set on a platform 20 ft. above the floor proper. The ore goes from the bin over a 1½-in. grizzly and the oversize passes through the crusher. The crushed ore with the grizzly undersize goes to a 3 by 6-ft. trommel with 1¼-in. punched holes, at which point water is introduced. The trommel oversize divides, going to two 20 by 6-in. Blake crushers which reduce it to ¾ in. Each crusher discharges to an elevator which dumps to a 100-ton feed-bin with sloping bottom, there being one such bin to each section. A 75-hp. induction motor drives the coarse crushers of each unit and all feeders, elevators, conveyors, etc., connected with them. One unit of the mill is served by the coarse crushing plant as described, but the following description will be understood to apply to only one section or one-half a unit.

From the feed-bin the ore goes to two 3 by 6-ft. trommels with ½-in. punched holes. The oversize of these trommels goes to a set of 15 by 36-in. Gates high-speed rolls' set to one-half inch, making 104 r.p.m. The roll product goes to an elevator which returns it to the trommels. A 35-hp. motor drives the coarse rolls, trommels, and elevators. The undersize from the ½-in. trommels goes to four 3 by 6-ft. trommels set in pairs, with ¼-in. punched holes. The oversize from each pair goes to a set of Gates rolls of the same size as the coarse rolls set to ⅛-in. and making 102 r.p.m. Each set of rolls discharges to an elevator which returns its product to the fine trommels. Two 50-hp. motors drive the fine rolls and attendant machinery. The roll-shells are of Latrobe steel and have a life on the coarse rolls of six weeks and on the fine of six months. The undersize from the four fine trommels flows by gravity to the feed-bin for the Chilean mills. At the discharge from the trommels it is sampled by a rather novel sampler, consisting of a sheet-iron bucket 12 by 8 by 1 in., which is carried through the stream on a belt and then automatically inverted.

The test runs, on the basis of which the mill was

designed, showed a considerable amount of ore that would jig, but when the time came to put the mill in operation the ore that was provided was found to be too fine for this purpose so that the jigs that were installed have been of no service. This has neeessitated a modification of the system, and the final design has not yet been adopted. The original plan was to classify the ore before it went to the jigs, and re-grind the tailing. At present in one unit the trommel undersize goes directly to the feed-bin for the Chilean mills and from them to the distributer for the table classifiers. In the other unit it is first passed over a traveling belt screen and the oversize sent to the mills which discharge as above. A third plan which is to be tried is to remove the screens from the mills and re-grind the oversize from the traveling screen. The mill product will be returned to the traveling screens by an elevator and re-classified. The undersize of the traveling screens will go to the distributer.

Each section has four 7-ft. Monadnock Chilean mills set at corners of a square. The mills make 24 revolutions per minute with four mullers. The tires are of Midvale steel with a face of 10 in. and a thickness of 4 when new. They have a life of five months. The screens are 16-mesh brass wire with a free opening of 0.025 in. The mills are set well above the floors on concrete piers so that the under mechanism is readily accessible for repairs. A 150 and a 50-hp. motor drive the mills. The mill discharge runs by gravity to a revolving distributer that divides the feed among the classifiers for the tables. The launders leading to the tables terminate in a tub 48 in. diam. Inside of this tub is a cast-iron cylinder with a spout driven by an overhead gear. The cylinder receives the feed, and in revolving discharges it to each launder in turn. On the table floor are 54 tables arranged in six rows of nine each. One row of James tables was installed, but after a try-out they were found to be unsuited to this ore and are not now in operation. At the head of each row of tables is a series of classifiers each of which feeds two tables. Each classifier is 15 ft. 8 in. long, 4 ft. 9 in. deep, 4 ft. 6 in. wide at the top, and 1 ft. 6 in. wide at the bottom. The pressure water is turned in at the bottom, the arrangement of hydraulic and discharge opening being similar to a spitzkasten, but there are no compartments in the classifier. The overflow of the classifiers runs to the slime plant.

The tables are a combination of two of the better known models of the Wilfley, having the deck and adjustment of the No. 5 and the head-motion of the No. 3, the latter being slightly modified by placing the spring under the toggles instead of under the deck. The No. 5 deck is self-contained and sets well above the floor so that it can easily be reached from beneath, while the No. 3 head-motion is considered the simplest and is the one preferred by many millmen. This combination has given excellent satisfaction. The tables have a speed of 250 strokes per minute, those treating the coarser feed being set to $1^1/_{16}$ in. and the finer to $\frac{7}{8}$ in. The first six rows make four products, concentrate, middling, tailing, and slime. A 20-hp. motor drives each double row, 18 tables. The slime goes to the slime plant, the tailing is rejected, the concentrate goes to a set of finishing tables, and the middling to classifiers on the level next lower than the main table floor. These classifiers, which are similar to those described, feed a row of nine tables which make three products, concentrate, tailing, and middling.

All concentrate runs to classifiers on the lowest floor of the mill to nine finishing tables making only two products, concentrate and middling. The ore is of so low a grade and the silicious content is so high, that it is impossible to make in one operation a product that will not run high in silica. The concentrate from the first operation assays as high as 35% SiO_2. By the finishing operation this silica is brought down 10 or 15%. As the valley smelters penalize silica and pay for iron at the rate of 10c. per unit, it will be seen that the finishing process is a paying one, equaling a reduction in the cost of milling of from 4 to 6c. per ton crude. As there is no reject from these tables there is no increase in the tailing loss. Another advantage is that the finishing of the concentrate in a second operation permits of a certain amount of crowding on the roughing tables which can be accomplished without any increase in the loss in the tailing, as it is not necessary to remove all of the silica in one operation, and the tables can be run flatter than is customary. This results in a closer saving with an increase in silica, the latter being removed in the second operation. The finishing also makes a reduction of 10 to 15% in the amount of the concentrate, with a corresponding saving in smelting charges.

The middling from the middling and finishing floors flows to an elevator by which it is raised to the top of the concentrate bins, from which point it is returned by a 4-in. centrifugal pump direct-connected to a 15-hp. motor to the feed-bins at the Chilean mills. The concentrate goes to an elevator which raises it to the bins. A 25-hp. motor drives the finishing and middling tables and concentrate elevator.

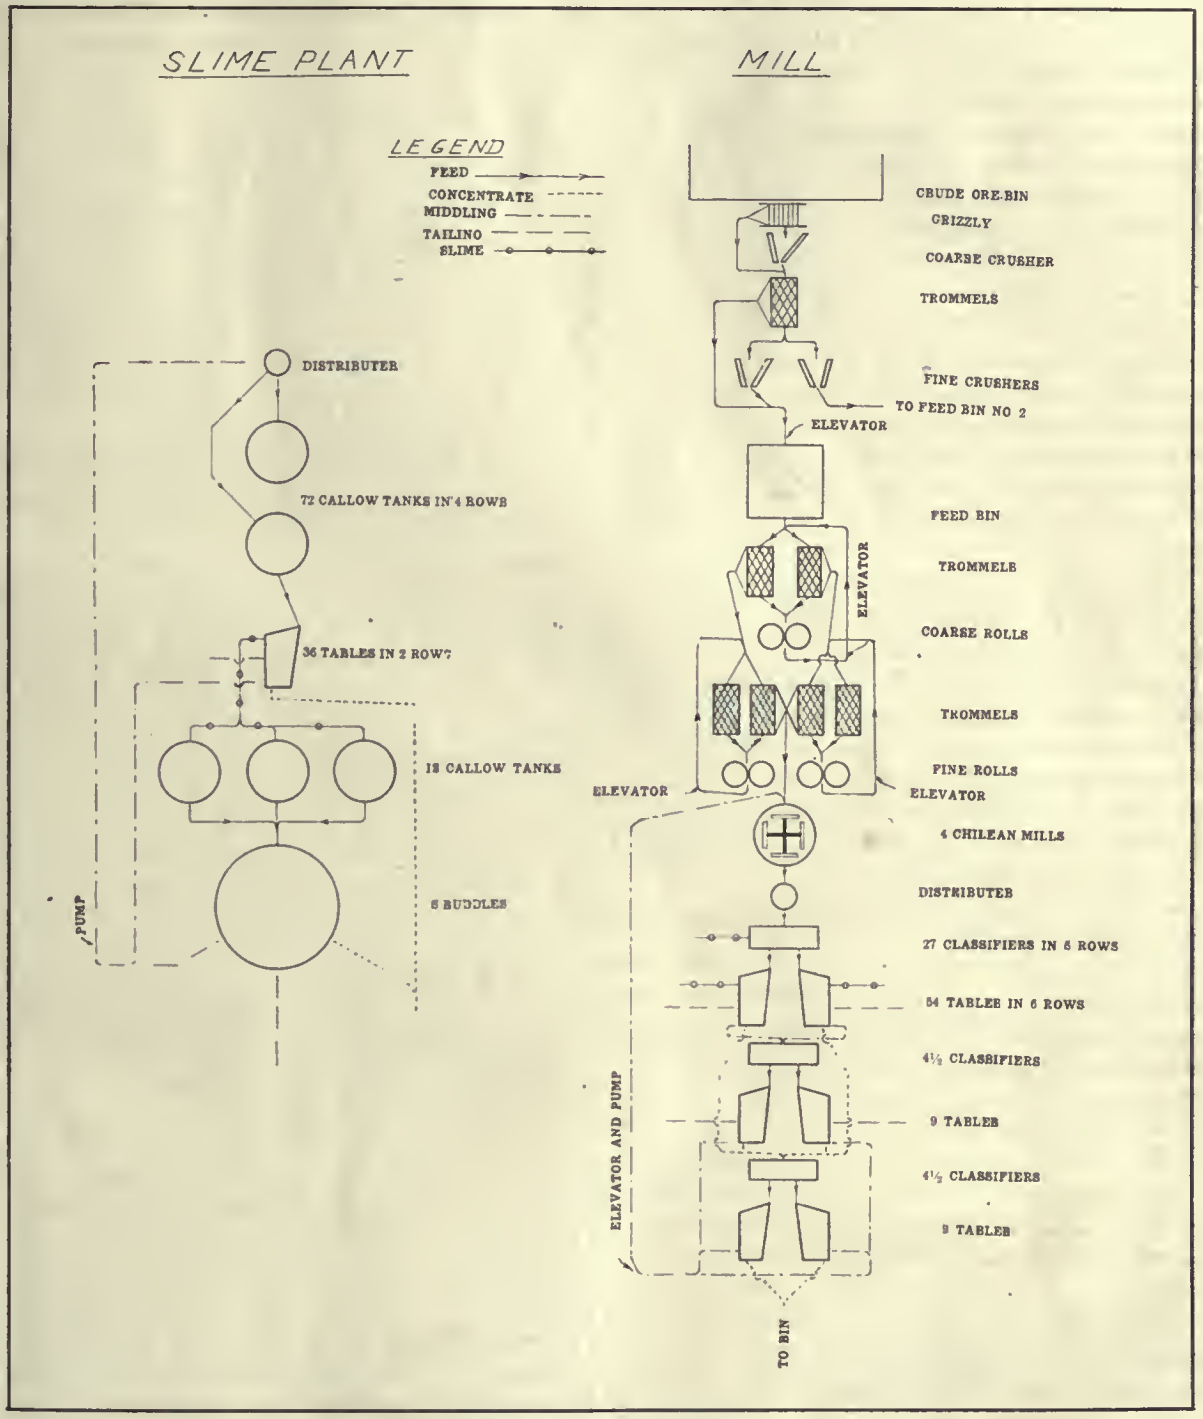
The bins are in an addition to the mill proper, in which a railway spur is so placed that the concentrate can be loaded directly into the cars. There are two bins to each section, so that one is draining while the other is filling. This makes eight concentrate bins arranged with four bins on each side. There are five overflow bins. The bins are 16 by 16 by 16 ft. tied by 1½-in. rods. The overflow runs to the nearest overflow bin and the fine particles of concentrate have a chance to settle. The stream overflows in turn to the next bin, and finally to the one in the middle. The overflow of this bin is used as wash-water on the middling and finishing floors. Each concentrate bin has a fine screen 12 in. wide covered with two thicknesses of burlap set diagonally across each corner for the full height of the bin. When the bin is full, plugs are pulled from the corners and the water in the concentrate is drained through the screen. When the bins have been emptied the screens are washed off with a hose. The bins are rendered watertight at the gates by means of a rubber gasket against which the gate is tight-

ened by a cam. Tailing and concentrate are sampled by water-operated teeter samplers. The tailing from both units mingle in one large launder and run to the tailing pond.

The slime plant is built in two floors and two units. One of these is in operation and will be described. The feed consists of the slime from the tables in the mill and the overflow from the table classifiers. This runs to a large revolving distributer which divides it among three smaller ones, each of which feeds 24 Callow tanks, a total of 72 tanks being arranged in two rows on each side of the table floor. There are two rows of Wilfley tables, 18 in a row, and each table receives the spigot discharge of two Callow tanks, the overflow being used as wash-water. These tables make 250 strokes per minute, and the stroke on so fine a feed must of necessity be very short. Some trouble was found in getting it sufficiently short, but this was finally accomplished by running the pitman above centre. This was tried with some doubt, as it was expected that the head-motions would pound themselves to pieces, but no trouble has been experienced from this source and the experiment has proved satisfactory. The stroke is about one-half inch.

These tables make concentrate, middling, tailing, and slime. The concentrate goes to an elevator belted to a 20-hp. motor, by which it is raised to a bin similar to those in the mill. The middling goes to a 4-in. centrifugal pump direct-connected to a 15-hp. motor, and is returned to the main distributer. The tailing is rejected and the slime goes to 18 Callow tanks on the lower floor.

Each three of these Callow tanks feed a 16-ft. single-deck buddle. The deck of the buddle is laid on an umbrella frame of eighteen 4 by 6-in. timbers



Flow-Sheet Ohio Concentrator.

and is braced by a like number of the same size slanting downward to the spindle. The deck is covered with neat cement with an outward slope of 1¼ in. to the foot. The table makes one revolution in 70 seconds, being driven by an overhead worm gear. The buddles make concentrate, middling, and tailing, each of which is washed off into a separate compartment. The concentrate goes to the elevator, the middling to the pump, and the tailing is rejected. The revival of the buddle, which many millmen have considered obsolete, is rather interesting. The feed, it will be noted, is the slime from tables which treat the slime of the mill; an impalpable pulp in which absolutely no grit can be noticed and all of which will pass a 300-mesh screen. It was feared that so fine material would not settle to the belt of a vanner, so the buddle was tried, and, according to the statement of the management, has been found to give as good results as could be expected on so fine a feed. Two 20-hp. motors drive all of the concentrating machines in each unit, and one 20-hp. motor the two elevators in the bin-room. A sump in the concentrate floor has been provided near these elevators in which any slop may be collected and settled. Concentrate and tailing are sampled by water-operated 'teeter' samplers.

The tailing is held behind an earthen dam and the surface water at the end farthest from the point of entrance is led to the pump-house. Here are two 12 by 12-in. single-acting Aldrich triplex pumps with a capacity of 1000 gal. per minute, each geared to 100-hp. Westinghouse induction motors, with provision for the installation of two more. These raise the water against an equivalent head of 250 ft. to the mill. The pipe is 24-in. wood, iron-stayed except for the last 320 ft., which is of iron,

A summary of the motors that will be used in the completed mill follows:

Machines.	No. motors.	Hp. each.	Total hp.
2 coarse and 4 fine crushers, elevators, 2 trommels, 4 conveyors	2	75	150
4 coarse rolls, 8 trommels, 4 elevators, 4 feeders	4	35	140
8 fine rolls, 16 trommels, 8 elevators	8	50	400
16 Chilean mills	4	150	...
	4	50	800
216 roughing tables	12	20	240
36 middling tables, 36 finishing tables, 4 concentrate elevators, 4 middling elevators	4	25	100
4 middling pumps	4	15	60
144 tables, 12 buddles in slime plant	4	20	80
2 middling pumps in slime plant	2	15	30
2 concentrate elevators in slime plant	1	20	20
4 1000-gal. return-water pumps	4	100	400
			2420

This number, 2420, divided by 2300, the capacity of the mill, gives 1.05 hp. per ton of ore treated.

The company buys hydro-electric power generated by the Telluride Power Co., but is supplied by the Utah Light & Railway Co. instead of direct, as the latter company has an excess. It is found more economical to buy the hydro-electric power than to build and operate a steam-electric plant. In the transformer house at the pumping station are three 100-kw. Westinghouse oil-water cooled transformers, stepping down from 44,000 volts to 480, with choke coils and lightning arresters. In the main transformer house at the mill are three similar transformers of 500-kw. capacity, three 44,000-volt choke coils, and lightning arresters. The oil switches are encased in concrete boxes with metal doors and the trunk lines are provided with time limit relays at the switchboard. All motors except those at the pumping plant are three-phase, 60-cycle, induction of General Electric make. The pumping motors are Westinghouse.

Under one crude-ore bin is a repair shop, and under the other a machine shop, where the work of the mine as well as the mill is cared for.

The water used is derived from the Mascotte tunnel, which gives a flow of 600 gal. per minute. The mill uses 4500 gal., the remainder being recovered. This high recovery is effected only by saving all that is possible, and the only water lost is that which evaporates and that remaining in the concentrate after it has been drained. About 18 tons of water is used to each ton of ore treated.

During the month of June the average amount milled was 1146 tons per day. Concentration was effected at the rate of 26 to 27 tons into one. The average of the ore is about 1.4% copper, and the extraction is 65%. The ore being treated is that which comes from close to the capping. It is lower in grade than the average run of the mine and contains a great deal of carbonate on which the extraction is poor. With a better grade of ore the extraction should improve, as within certain limits the loss does not increase at the same rate as the percentage of copper. With the ore taken from greater depth, where the carbonate no longer appears, there should also be an improvement in extraction. The average of the concentrate is somewhat better than 24% copper, and the production at half capacity at the rate of 7,500,000 lb. per year. With an ore running 1.75% copper and an extraction of 70%, both of which, if apparently reliable reports are to be accepted, are possible, the production would go well in excess of 10,000,000 lb. per year. The concentrate is being shipped to Garfield for smelting and converting. While, in view of the threatened competition at Tooele, the contract is supposed to be a favorable one, the company does not desire to make a statement of costs while operating at only part capacity. Production should be accomplished at a reasonable figure, as the ore can be mined and milled cheaply, but there is no doubt that a recent unofficial statement which placed cost of production at 7½ to 8c. per pound was far too optimistic. The writer wishes to acknowledge the courteous assistance of William A. Kidney, superintendent of the mill, in collecting the notes for this article.

The lead and zinc mines of northern Illinois are all in Jo Daviess county, the extreme northwest county of the State. The ores have the same structural relations as in the upper Mississippi district generally; that is, they occur disseminated through dolomite, or in openings called 'crevices,' 'pitches,' or 'flats,' depending on their attitude to the horizontal.

Water Conditions in the Oil Field at Coalinga

By R. P. McLaughlin

Within the past few months considerable publicity has been given to the troubles experienced from water in the oil wells of the Coalinga, California, oilfield. A definite statement of conditions and causes of the publicity will doubtless clear up some misconceptions. The last Legislature passed a law authorizing the appointment of Oil Well Commissioners by the supervisors of various counties. The duty of the Commissioner is to investigate the cause of trouble in wells that are flowing a high percentage of water and damaging surrounding properties, and to correct such errors if possible. Such a law is very easily written upon the statutes but the difficulties of enforcement are twofold. First the owners of the offending well may be indifferent to the damage being done or financially unable to correct it, and second, the problem may be extremely difficult to solve owing to unexpected conditions underground.

In Fresno county the salary of the Oil Well Commissioner is paid entirely from the county funds and amounts to $100 per month. As the rate of pay of skilled laborers in these oilfields is in the neighborhood of $175 or $200 it can be seen that the Commissioner has an individual problem in domestic economy, especially if he attempts the necessary traveling in discharge of his duties. In view of the above mentioned difficulties the results obtained have not been great. The present Commissioner, R. Baker, has done as much as was possible and the board of supervisors has shown a willingness to give more help to the oil producers if some practicable scheme were presented and supported by them.

Several months ago the Commissioner called a meeting of those interested and after considerable discussion a committee of eleven was appointed to draw up a plan of co-operation. A scheme was presented for the formation of an association of all the operators through which such information as is necessary could be collected. An office was to be maintained in the town of Coalinga, a geologist employed with such assistants as he should need, and power delegated to the executive committee of the association to enforce remedial measures. The proposed articles of agreement were submitted to the officers of every company in the field, with requests for suggestions as to improvement, acceptance, or rejection. Practically no objection to the scheme developed though there were some suggestions as to alteration of details. The number of replies was so small, however, that the organization was not assured. Steps have since been taken to obtain direct answers from the companies through their various resident superintendents. The matter is in the peculiar condition of having met no opposition and being generally approved by most of the people aware of the conditions, and still the committee lacks power to proceed. It has become evident that corporations are loath to delegate power to any committee to dictate as to the conduct of operations at any well. Considerable doubt as to the power under the present law to really accomplish anything is also manifest. Most, although not all of the operators, concede the advisability of having data collected and presented in the form of cross-sectional drawings of the logs of wells.

The total estimated cost of the scheme would be equivalent to a charge of about one mill per barrel of oil produced. The plan provides for a geologist who would watch the drilling of all new wells and thereby be able to correlate the logs. The sum estimated would permit employment of competent and experienced men for this work. At present the logs are kept by different individuals without attempt to strictly classify the formations passed through and are frequently of no value aside from showing the depth at which oil is found. Water is rarely mentioned in the written logs though it is a most important item. The upper portion of the logs has been considered of little value and such strikingly characteristic beds as gravel or large fossils are seldom recorded. These would, if systematically recorded, afford enough data to almost exactly tie neighboring logs together and give a basis for predictions during the drilling of any well. Many logs are recorded merely from what can be observed by the driller within the derrick. This should be supplemented by careful scrutiny of all the drillings dumped. Some of the larger companies, especially the K. T. & O. (Southern Pacific company), follow such a scheme as outlined and thus have accurate records of all work that may be readily shown by drawings.

The Coalinga field is probably one of the most simple in structure and regularity of beds, and more good could thus be accomplished by co-operation here than at many other places. Water conditions are far from being hopelessly bad and the field has not shown any evidence of general encroachment of water. Water is frequently carried in a bed above or below an oil-sand and unless carefully handled and cemented off leaks into the oil sand. In some cases enough water is found to entirely smother or hold back the oil, while in others only a small percentage comes in with the oil and settles out in the sump-holes. One company is pumping oil with water in such fine globules that it will not naturally settle and requires electric treatment. There have been about 1000 wells drilled in the field, about 30 show water in amounts greater than 25%, while about 50 wells have been abandoned. Not all of the abandoned wells are chargeable to water troubles but probably a majority are and as the cost of drilling a well will average about $20,000, it will be readily seen that lack of system has already cost a considerable amount. As is usual in any new departure the value of technical work is looked upon with considerable skepticism by those who have heretofore obtained creditable results from 'rule of thumb' methods. However, the subject is in the way to be given thorough consideration and perhaps a fair test.

Mining Industry in Japan

By T. Haga

The total number of applications for mining rights in 1909 amounted to 4335, a decrease of 326 or 7% as compared with 1908. This was chiefly due to decrease in applications for prospecting; there was some increase in applications for working rights. In 1906 and 1907 the applications for prospecting increased remarkably in accord with the general boom in all enterprises and the rise of mineral prices. Since 1908, however, they have gradually decreased, on account of the depression of business and the fall of mineral quotations. At the end of 1909 the number of mine-lots granted for prospecting was 4037, a decrease of 1149 or 22%, and the number of commissions for working was 5553, a decrease of 21. Alluvial mine-lot concessions in 1908 numbered 1608, a decrease of 699 or over 30% over the number in 1907. Since 1908 there have been numerous cancellations at expiration and fewer applications. The working mine-lots, though not increased in number, do show increases in area year by year. In alluvial mining the output in magnetic sand did not show any remarkable change though a number of concessions were cancelled in 1908. The output in alluvial gold increased remarkably, particularly since its discovery in Hokkaido. Owing, however, to the imposition of an extraordinary tax, it decreased nearly half and still shows a decrease year by year. In 1909 the staple mineral products, gold, silver, copper, iron, and sulphur (with the exception of those of the naval possessions and Formosa), showed an increase of 7 to 20% and coal and petroleum showed an increase not less than in the year before. The production of the staple minerals for the past ten years has increased year after year steadily and in case of silver, copper, coal, and petroleum, the rate has been remarkable. The output in 1909 of gold and silver in comparison with that of ten years ago, 1899, shows an increase of 90%; silver, iron, and petroleum increased 120, and coal 100% in the same decade.

In the aggregate the trade in minerals of 1909 was Y96,450,213, exports being Y43,221,316 and imports Y53,228,897. The excess of imports was Y10,107,581. There was an increase of Y278,760 in the value of the exports, and a decrease of Y14,846,675 in the value of imports as compared with 1908. In short, the figures show a decrease of Y14,567,915 in the value of both exports and imports. The total volume of exports and imports in minerals amounted to a little over Y82,260,000 in 1905 but suddenly reached over Y103,960,000 in 1906 and over Y126,250,000 in 1907. Since 1907 there has been a slight decrease, yet the total amounted to over Y96,000,000 in 1906. The principal of exports are copper, coal, and sulphur. The exports of copper for 1906 to 1909 amounted to over Y22,790,000 per year; those of coal to Y17,920,000, and of sulphur over Y1,140,000. They all show increases year by year. The principal imports are iron, steel, petroleum, and phosphates. The imports of these articles are decreasing, especially imports of iron and steel.

Investment in mining during the past five years, 1905-1909, aside from that of individuals, shows an increase both in the number of companies and in capitalization. The number of companies was 233 in 1909, as against 195 in 1907, and 132 in 1908. The total registered capital amounted to over Y181,300,000 in 1909 against over Y171,000,000 in 1907; an average increase of over Y80,000,000 or 22.7%. Market quotations in 1909 were constantly inactive. The prices of all the minerals showed decreases but compared with the previous year, the amount of fluctuation was small and at the same time there was no great difference in quotations. During the last half year, the tone was upward, and still active at the end of the year. The coal market was affected by the general commercial and industrial depression, and stocks accumulated. The price of coal fell from 12 to 5%. The decrease was especially remarkable in Tokiwa and Karatsu districts. In all Hokkaido districts the price was much depressed, but the most famous Chikuho district was steady. The petroleum market, which has been active for years, in 1909 became suddenly dull, and still is so. During 1909 the disasters in mines number 14,489, which resulted in 554 deaths, 229 seriously wounded, and 14,254 slightly wounded. The number of deaths showed an increase of 239 in comparison with 1908, due principally to a great disaster at Oura coal mine, Fukuoka, in which officials and miners killed, numbered 243.

It is claimed by some mill-men that a mill of the Chilean type does not work to its highest capacity if run at high speed—60 to 80 revolutions per minute—as in this case the pulp partakes of the rotary motion of the crushing wheels, and the latter do not, in consequence, overtake the granules of rapidly rotating pulp as effectively as where the mill is run at slower speed. A speed of 360 to 400 ft. per minute is thought to be correct, by those who advocate slow speed. This is a matter that may be determined easily by careful experiment.

Not longer than ten years ago it was considered the proper thing, in order to increase the duty of the gravity stamp, to place some sort of auxiliary crushing device between the rock-breaker and the stamps. This was usually either a second crusher, reducing the rock to still smaller size, or a set of crushing rolls, to re-crush the oversize from the first breaker. Today it is almost universally the practice to re-grind after the stamps, as it has been found the desired fineness of pulp can be produced less expensively and more evenly by the latter method.

The first electric-transmission plant for mining in California was installed at the Big Bend mine on Feather river in 1888, and the second at the Dalmatia mine in El Dorado county, in the latter part of the same year. These lines were both short—a mile or two. The Standard Consolidated mine plant at Bodie, California, was twelve miles or more in length and was built in 1893. This was the first of what might properly be called long-distance plants for mining enterprise exclusively in California.

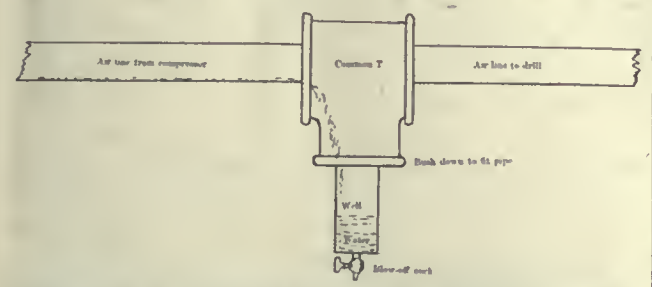
Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Device to Free Air-Line of Water

The Editor:

Sir—Having had considerable trouble with water in the air-line, I was told by a friend to try the following described scheme, and found it to work successfully, and have had absolutely no trouble from that source since. The device is easily and quickly made, costs but a trifle, and has given entire satisfaction. Take a common 'T' twice the size of the



air-line, or at least larger than the air-line, screw in a nipple 12 to 18 in. long, to provide a well for the condensed water, fit the nipple with a pet-cock, or valve, at the bottom end to blow out the water which collects in the well, screw this onto the pipe-line, and extend the line on to the drill. All water collecting in the pipe or air-line drags along the bottom of the pipe and drops into the well, and by blowing the well out occasionally, all trouble from that source is overcome. It is best to have this device as near the drill end of the line as possible.

Cyanidation of Sulphides

The Editor:

Sir—This is not only a subject of interest, but of importance to the mining world. For the last seven years I have studied and experimented along these lines, meeting with encouraging success. In some cases results were almost unbelievable, in fact disputed, but I produced the bullion at the 'clean-up' which corresponded with assays, and that is, after all, the most convincing argument. I do not claim to have discovered a new process, but the successful application of the bromo-cyanide process. At three different well known mines where I have installed plants, different treatments are in vogue. The same strength of solution and quantity of bromine does not apply to all sulphides, but, like treating different tailings, a specific treatment is of course essential.

I shall only cite in this letter the treatment I employed on the concentrate at the Black Oak mine, Tuolumne county, California, in 1905; this being the most interesting on account of the high content of gold and silver. The concentrate contained sulphide of iron (pyrrhotite), galena, and copper. Occasionally the content of galena ran as high as 4%, but the copper never exceeded 2, and was generally nearer 1%. The silver was mostly in the form of a sulphide. There was about 3½% of sulphide in the ore, which, when concentrated, represented six different products, ranging in value of $100 gold, 20 oz. silver, to $2000 gold, 160 oz. silver per ton. Only about 500 lb. of the latter product was made each month. It was all cyanided and turned into a bar, averaging an extraction of 99% and over, on 30 tons (a month's run), at a cost of $5 to $8 per ton, the cost depending on the value of the tailing. The Frue vanner product (designated as No. 1), was the coarsest material treated and showed beyond all doubt the advisability of fine grinding; for, on comparing the tailing value with that of the tailing from other products treated, which were finer, the No. 1 tailing always ran $1 to $2 higher. While these were the coarsest treated they could be considered fine in comparison with the average of concentrate, for the mill crushed to 60-mesh. The average value of No. 1 concentrate was $100 gold, 20 oz. silver per ton.

The treatment began at the machine where concentrate was produced. If at the vanners, the sulphides were hoed out into the front settling box, and let stand for eight or ten hours. Every half hour during that time they were pounded with a shovel. They gradually packed and settled under this treatment, so that at the end of eight hours they were very hard and solid and contained only 12 or 14% moisture. The water was then bailed off and sulphides shoveled out. The product is easier to handle, there is less loss, no extra cost, and this method is to be recommended on the ground of its neatness alone. On the accumulation of 3000 lb. or thereabout, the concentrate was trammed to the cyanide plant, spread out in the sun, and dried to about 2 or 3% moisture. Winter conditions, of course, interfered with this treatment, necessitating the discarding of this preliminary operation which always resulted in a little higher tailing loss. Steam drying improved this a little, but nothing we could do would bring extraction up to that on a sun-dried charge. My theory for this is that the sun in drying out the moisture, split or fractured the particles, making them more porous, and the sulphides took up more or less oxygen in drying, and being dry, helped the solution to penetrate by absorption. The charge treated by agitation, consisted of 3000 lb. net weight (carefully weighed, moisture determined, and sampled for 'heads' assay), 2000 lb. net weight of water (solution), about ½ lb. of liquid bromine, and 40 lb. of cyanide (2% solution).

The agitation tank is of special construction. It should be of steel in preference to wood, or wood, steel lined. In fact steel should be used instead of iron, wherever a wearing surface comes in contact with pulp. I advise the use of steel shoes and dies in all mills where cyanide is used. A higher extraction and less cyanide consumption, is my experience. The agitator used was made approximately air-tight, so as to have the charge, while agitating, under a slight air or gas pressure. It has a trap door in the top for the convenience of loading.

After sulphides and water are in the agitator the bromine was added and the trap door closed imme-

diately to retain fumes which, while heavy, would soon be fanned out and lost. I believe these fumes perform just as much work as the liquid dissolved in the water. The charge was agitated a half hour before cyanide was added, and the air started, putting the charge under a slight pressure which was maintained during the whole of the agitation. About four hours after adding cyanide the largest consumption had taken place. The extraction at that time was about 90%, 18 hours more being required for the remainder. At the end of the 22 hours' agitation the charge was discharged into a rectangular vacuum tank, and then solution was drawn through the filter, leaving the sulphides, with about 20% of the pregnant solution. This was displaced by wash-water. On being thoroughly washed the tailing was sampled for assay, and then shoveled out. Seldom more than 30 of the 40 lb. of cyanide would be consumed; more often 20 lb., sometimes as low as 10 lb.—this depending altogether on the quantity of magnetic iron present, and the amount which went into solution. The gold was invariably extracted regardless of large or small cyanide consumption. The silver was always more or less of a worry. If the cyanide consumption was small at the end of the 22 hours, the silver was always extracted. If cyanide was nearly all destroyed, the solution would be dark, and the silver lost. This seemed to be due to the iron going into the solution and precipitating the silver. This could only be avoided by constant vigilance toward the end of the treatment as it was at that stage the trouble would occur if at all. The average tailing value on No. 1 sulphides when not sun-dried before treating, was $2 gold, 2 oz. silver per ton. These same sulphides sun-dried, averaged $1 gold, 1 oz. silver per ton.

The other products were treated in much the same manner with about the same strength cyanide and bromine. Although much richer they were easier to treat. The reason for this was their extreme fineness. No. 2 product, which was caught on the canvas plant, ran $250 gold, 50 oz. silver per ton, received the same treatment as No. 1, and gave an extraction of from 99 to 100%. Seldom more than 60c. was left in the tailing. When the material was sun-dried, often only a trace was left. Another canvas plant product (No. 3) ran $150 gold, 30 oz. silver per ton, and gave the same results as No. 2 with less cyanide, 1.5% solution and the same quantity of bromine being used. The high-grade concentrate, $2000 gold, 150 oz. silver per ton, was obtained from the side settling boxes on Frue vanners where the very fine sulphides would float and finally settle. These were either treated by themselves or mixed in with the No. 2 product. Zinc shavings was the means of precipitation. The solution, while always strong in cyanide, was built up in alkaline strength with caustic soda, 2 lb. to the ton, before entering zinc boxes. A small steady stream should flow in the boxes. Sudden starting and stopping will cause a loss by loosening the adhering particles and carrying them on down. About 95% of the gold and silver will precipitate in the first three boxes, but from 10 to 18 boxes are used as a precaution against loss. I have never yet allowed more than a trace to be found in 10 assay tons of solution on leaving the zinc boxes. I do not believe that a higher tailing solution value is necessary in any plant. The zinc-box tailing solution may be used again on making up a new charge, bringing its strength up with additional cyanide.

These were the results at one mine, but I have had the same success at others. In one case the concentrate was three or four years old, badly decomposed, and assayed $30 to $40 gold per ton. There was 700 tons piled up—it costing as much as the material was worth to ship to smelter. The mine was 60 miles from the railroad. This concentrate was treated at a cost of $10 per ton, including the tailing loss. There are many other mines in similar situations where concentrate is not worth saving owing to the high cost of shipping. The cost is not all in freight and smelter treatment charge. Sacking, hauling, and the wear on sacks, is quite an item. Taking $100 concentrate as an example—95% of the assay value is paid, $5 being lost to the shipper; $20 per oz. is paid; were it bullion the price would be $20.67; and on 5 oz. the loss is $3.36 more. It is not necessary to review the moisture disputes and dissatisfaction, but summing up the total cost, it will be found that a liberal margin can be allowed for the treatment of concentrate by cyanidation.

A Cyanide Problem

The Editor:

Sir—I will not pretend to be astonished at the caustic reply of 'Metallurgical Engineer' to my inquiry for information in regard to the treatment of auriferous and argentiferous ores carrying antimony, for I am not. I have had the opportunity to read most of the works on the cyanide process, including those by Scheidell, Bosqui, James, Louis, Park, Clennell, Julian and Smart, and several others, besides numerous classical contributions on the subject from every gold mining field of importance in the world, and must confess that the most diligent search has failed to discover anything of consequence, and I may add, of value, on the question in point. Since this is so, our friend, 'Metallurgical Engineer' is to be congratulated on the possession of the secret—or are all of these excellent and experienced engineers holding this particular card up their several sleeves, with a view to turning it to good commercial advantage? This I do not believe, for almost every phase, it would seem, of the application of the cyanide process in its many modifications to ore treatment has been elaborated and all secrecy banished, in the lengthy, and sometimes acrimonious, discussion of various matters. It would be strange indeed if this one lonesome vexed problem were the only one left undebated. I learned many years ago that an attempt to create a 'corner on knowledge' was almost hopeless, and I think this instance will prove to be no exception.

ST. PETERSBURG, RUSSIA

Far Eastern Goldfields.—New Fields on the Okhotsk.—Geological Surveys.—Dredging in Siberia.—Exploration of Sakhalin.

The Far Eastern goldfields which, according to some reports, are of fabulousiy high content and according to others again of very low grade, are coming gradually into prominence as centres of gold production. There is no need to make reference to the extraordinary operations said to have been conducted by the North Eastern Siberian Co., which, under the pretense of being a gold company, it is held is dealing rather in furs and whisky, or again to the alarming rumors on the part of some Russian patriotic enthusiasts who maintain that the Americans and Japanese between them, particularly the former, are getting fast hoid of the mineral riches in the Okhotsk area; and becoming, as a matter of fact, dictators to the local population, which looks to them rather than to the Russian Government, as an ultimate court of appeal. The fact of the political supremacy of the Russians in the region named, makes the reports that appear in the Russian press prob-

Sending Gold to Government Assay Office in East Siberia.

abiy the most reliabie that can be had on the subject of the mineral wealth of the district. The 'Praviteistvenny Viestnik,' which is a Government organ, has announced that in the course of the present year, 1910, a new auriferous district has been found in the Okhotsk marine area near the well-known port called Anna on the Okhotsk Sea. The district includes parts of the basins of the Aldama, Lantar, and Nemuya rivers. The 'Dainy Okrain,' announces that in this new region one gold contractor has taken up 100 allotments, while altogether 200 will be allocated. The new area extends over 300 versts (200 miles) along the coast of the Okhotsk Sea. It has a breadth of about 40 versts (27 miles), and it first came into notice about fifteen years ago when the Minister of Agricuiture and Government Properties suggested to the Committee of the Siberian Railway, the advisabiiity of organizing a detailed investigation of the auriferous deposits of Siberia and particularly of studying the auriferous shores of the Okhotsk Sea, the western shore of Kamchatka, and the Shantar islands. In the year 1895, an expedition was sent out under K. Bogdanovitch, mining engineer. After a preliminary reconnoissance and detailed geological investigation of the area, the presence of gold was established in many of the river valleys between the left bank of the river Uda and the port of Ayan, as also on the upper parts of some of the rivers of the western shore of Kamchatka. These surveys showed the presence of gold chiefly on the Aldama system and its branches. One of the tributaries on the right, about half way along the course of the Aldama—Kaiegakot, in some places showed as much as 10 zolotniks per 100 poods of sand (about $20 per yard). This bed, which was about 1 ft. 9 in. thick, lies about 2 ft. 4 in. under the surface. The climatic conditions of the mountainous district of the shore land of the Okhotsk Sea between Uda and Ayan, have certain peculiarities due to the proximity of the sea, such as frequent wind storms in the winter and autumn. From Nikolaieffsk to Ayan much snow falls. The period between the thawing and freezing of the rivers is generally between the months of May and October. The average temperature for the period 1896-97 as observed in Ayan, was for December, —24.5° C., January, —26°, February, —16°, March, —10°. In order to mine on the shores of the Okhotsk Sea provisions, mules, and workmen must be carried there by water. The opening of navigation in the Ayan district may be counted the end of June, and at Tchumukan or the mouths of the Nemuya, about the middle of July, and sometimes even later, as was the case in 1907. The bay of Udska remains closed with floating ice almost until the middle of August. The latest period for the sailing vessels from Ayan is October 23 to 28. Consequently under the most favorable conditions, the season may be calculated to last about 90 days. With the present intimate knowledge of the conditions of navigation in the Okhotsk Sea this period might be increased, but for no more than fifteen days.

The Far Eastern goldfields of Siberia hitherto worked have been entirely alluvial, or practically so. They are, therefore, good grounds for the application of dredges, the chief difficulty being the long winter season. It is interesting to know that experiments have been made in northern latitudes of Siberia in the working of dredges practically throughout the whole winter and with considerable success, the cost not consisting, as it turned out, so much in the wear and tear of the dredge as in the difficulty of maintaining the staff at the requisite level of numbers and good condition in point of health. It must not be forgotten in the studying of this question that in those latitudes perpetually frozen ground has frequently to be dealt with. While this is not peculiar to Siberia, it is a matter of importance none the less.

Not long ago an expedition left St. Petersburg for Sakhalin, organized by the Geological committee, with the express object of investigating the gold deposits which are to be found there, in crystalline schist. This expedition will investigate an area occupying about 9000 square versts. One section of the expedition, under the guidance of the geologist, N. P. Tichanovitch, who is accompanied by two military topographers, will examine the eastern part of the island. The second section, under the guidance of P. I. Polievog, mining engineer, who is also accompanied by two military topographers, will undertake the investigation of the western portion of the island, in that area which touches the rivers Toima and Parona. Both these engineers last year investigated the island of Sakhalin for naptha and coal; and as a result of their efforts, fifteen occurrences of petroleum and a great many coal deposits were found.

LONDON

Dunderland Iron Ore Co.—United Alkali.—Botallack Pitchblende.—National Minerals Corporation.

The Dunderland Iron Ore Co., operating in Norway, is about to try a new magnetic separator, namely, the Ullrich, made by Krupp of Essen, Germany. These deposits have been developed on a gigantic scale and vast sums have been spent on dry concentrators, all to no avail. The ore consists of low-grade hematite and magnetite, and contains phosphorus. In the Ullrich machine the separation is done entirely under water, between electro-magnets below and a revolving disc containing concentric circular poles above. The iron in the stream of pulp is attracted to the revolving poles and as the disc revolves and carries the particles out of the field of the electro-magnets, a downward current of water washes the particles off and delivers them into another receptacle. Henry Louis, consulting engineer to the company, and D. A. Bremner, manager, report hopefully of the machine, but they wish to see the large scale tests carried out before finally forming a judgment.

A few years ago the United Alkali company introduced

a wet method of removing arsenic from sulphuric acid produced from impure iron pyrite. The inspector under the alkali act reports that this or similar processes are now at work at fifteen sulphuric acid works in Great Britain. These processes are important nowadays when so much starch is saccharized by acid; and also they make it possible to produce pure acid from poor quality pyrite. In the United Alkali process, the sulphuric acid is first brought into contact with a reducing agent in order to bring the arsenic to the arsenious state, and then exposed to the action of dry hydrochloric acid gas. The result is that arsenious chloride is formed. This being an oily liquid most of it can be separated by settlement. In order to remove the remainder, air is blown through the acid. The chloride comes away as a vapor, and on being brought into contact with water in a scrubber is decomposed into arsenious acid and hydrochloric acid.

From time to time rumors have been circulated to the effect that pitchblende has been shipped from the Botallack mine, Cornwall. It is therefore interesting to record the official notification that the pitchblende supplied to the Curie laboratory in Paris is the most radio-active of any ever received at that institution. A contract has been arranged for the delivery of all pitchblende found at Botallack within the next three years. No details are given as to the price but the fact that much labor is diverted to the discovery of pitchblende patches in the Wheal Edward part of the property, shows that the business promises to be profitable. The development of the Botallack mine has been hindered recently by the refusal of the miners to work below the 70-fathom level in the new Allen shaft, owing to their remembrance of water remaining at about this level in the Crown .part of the mine extending under the sea. To meet the request of the miners, the old shafts in this portion of the mine were reopened and pumps put in to reduce the water-level. This having been done the sinking of Allen's shaft was resumed. In the course of subsequent sinking a promising tin lode was found not far below the old water-level. A cross-cut is to be driven when a depth of 90 fathoms is reached in order to test its continuity. It is interesting to record also that further supplies of power are to be brought from the new electric generating station at Hayle. The inability of the directors to find further capital for the purpose of once more reopening the Hingston mine in East Cornwall is greatly to be regretted. When this mine, together with Gunnislake Clitters and other old properties, was acquired by an Anglo-German group now identified with the National Minerals Corporation ten years ago and modern plant including magnetic separators erected, it was thought that a new era had arrived in Cornwall. The subsequent history is sufficiently well known and need not be repeated now. Mr. Allen, who found capital to restore the mine after the collapse of the company and concurrent flooding, has not been able to persuade anybody to provide the further £25,000 necessary to develop the mine and remove the dressing plant from Clitters to Hingston. The Clitters mine has never been worked below adit, and the orebodies do not give sufficient inducement to follow them down, but at Hingston there are better prospects, and seeing that there is a dressing plant ready provided it is a wonder that somebody does not have the courage to come forward.

I have from time to time referred in a critical spirit to the doings of the group operating the National Minerals Corporation and during recent years controlling various schemes in Cornwall, notably Falmouth Consolidated, St. Ives Consolidated, and St. Agnes Consolidated. These three 'consolidateds' consist of groups of old mines abandoned by the Cornish miners. Whether the shareholders will ever get anything is a remote point; the promoters are doing well enough. The latest news is from the St. Agnes Consolidated. This company has paid to the promoters shares nominally worth £137,466 for a number of abandoned mines, full of water, and of no recorded value. The company also acquires from the National Minerals Corporation the agreement to purchase the West Kitty, an active mine but in desperate straits. The St. Agnes Consolidated has raised only a small amount of working capital so far, quite inadequate to the requirements. The National Minerals Corporation has erected an experimental electric smelter at St. Ives, Cornwall, supplied with current from the generating plant of the St. Ives Consolidated. Some six months ago the Corporation announced that a patented process had been acquired, and that by its means the total content of the ore could be recovered. In recent years several metallurgists have tried to apply electric smelting to complex Cornish ores. One of the most interesting was the experiment on tin slag, of which there are enormous heaps at all the five smelters. This slag contains most of the wolfram and iron, and a small proportion of the tin, contained in the concentrate commonly called 'black tin.' Some electrometallurgists thought that electric heat without addition of carbon would effect a concentration by melting, but the valuable constituents of the slag are so near the same specific gravity that such a proposition was futile. By the addition of carbon a reduction takes place in the electric furnace and a semi-alloy containing the metals is obtained. The subsequent separation of the metals depends on the recovery of wolfram as tungstic acid. All these processes are, however, complicated. The cost of current is an important item, and the wolfram product is not the most profitable. The prospects of working such a process at St. Ives are of greater promise from the scientific than from the economic point of view.

COEUR D'ALENE, IDAHO

Caledonia Mine.—Nabob Mining Company.

The Caledonia mine is situated near the head of Deadwood gulch which opens into the Coeur d'Alene just below Kellogg. The mine is in the neighborhood of the Bunker Hill & Sullivan, and one of the Federal groups. It is opened by a 42° incline, which was driven 500 ft. in the quartzite foot-wall of the vein, the inclination corresponding to the general dip of the vein. This shaft has two compartments, one for a ladder-way and the other for a 2-ton skip. An ore-loading pocket has been put in just below the 300-ft. station from which about 700 ft. of driving has been completed on the vein showing a width of 7 to 20 ft. A force of miners are working in three stopes above this level, which have been carried up from 25 to 60 ft. The ore found on the 300-ft. level and in the stopes above it contains lead carbonate and silver, the latter occurring as chloride, native, and in tetrahedrite. The next hoisting level is at 500-ft. depth, at the foot of the incline. The driving on the vein from this station amounts to 500 ft., and several stopes are being carried above it. Three intermediate levels between the 300 and 500 serve as the basis for stoping operations. These intermediates connect with ore-chutes leading from the highest one to the 500-ft. level. The ore found on the 500 and the lower intermediate levels here changes to galena, sulphide of silver, and tetrahedrite. Hand-drilling is the method by which a good deal of the ore is broken, though there are air-drills in the mine. In the course of the work a great deal of fine ore results and a lot of this is sacked and some of it is hand-jigged at the surface. It is announced by Charles McKinnis, the manager, that a concentrating mill will be built next year. In the meantime a cross-cut adit is being driven from Deadwood gulch to tap the ore several hundred feet below present workings. It is probable that the mill-site will be at the mouth of this. A Gould electric pump, set below the 500-ft. station, is able to keep the lower workings free from water. E. D. Booth who has charge of the mine work, states that they are hoisting about 45 tons of ore per day.

The Nabob Mining Co. has a property on Pine creek, 2½ miles southwest of the Bunker Hill & Sullivan group, which has been developed by about 2000 ft. of work. Recently a 40-hp. gasoline engine and air-compressor were installed at the mouth of a 336-ft. adit. The plan is to drive 1200 ft. farther on this adit to cut 145 ft. below the bottom of a 365-ft. shaft, and then make a raise to the shaft. Two cars of ore shipped sampled 55% lead, with a good deal of silver. The vein is said to have a width of 18 in. to 5 ft.,

and a considerable tonnage of ore is already developed. Harvey M. Ross of Kellogg is manager.

SALT LAKE, UTAH

Tooele Smelter.—Utah Copper Curtailment.—Daly West Report. —Beck Tunnel-Uncle Sam Suit.

The most interesting items in this district are the commencement of operations at the new Tooele smelter, and the steps which are being taken toward a temporary curtailment of the copper output. At the smelter ore was started through the sampling mill on August 4 and the first furnace was skimmed on August 15. The plant was in operation within the time allowed, thirteen months from the completion of the railroad, and was constructed within the appropriation set aside for it. Operations so far have not been attended by the trouble which almost invariably attends the starting of a new plant of any kind but, on the other hand, have gone along with remarkable smoothness. Two of the furnaces are being fed with Utah Consolidated ore and a third is almost ready for warming up. The first copper will be cast into souvenirs and distributed by the management.

Aside from closing the Copperton mill the Utah Copper Co. is curtailing production at the other mills. During the first half of August the average daily tonnage was only 13,104, whereas it has been in the neighborhood of

Open-Cut Mining at Bingham Canyon.

16,000 previously. This would indicate a decrease in production of about 20%. No reduction has been made in the force of men employed as the company will devote the time of curtailed production to development. August 16 a cave occurred in the old Boston Consolidated workings, 252 ft. of drifts in the porphyry being destroyed. Fortunately the accident occurred during the noon hour and what might have been a terrible tragedy was averted. Some days will be required to repair the damage done. The second quarterly report of the Utah Copper Co. states that all underground work will be discontinued at an early date. During the quarter surface stripping on the Boston Consolidated portion of the property was resumed and additional equipment was put to work on original Utah Copper ground.

The second quarterly report of the Daly West which was not sent out at the time of the checks for the dividend has been issued. It shows a net profit of $12,500 over all expenses including dividends of $54,000, but adds that developments for the quarter were disappointing both in the amount and grade of ore opened. The report announces that operations will be suspended in part until the lower levels of the mine can be proved and if conditions are found to be satisfactory a new mill will doubtless be constructed at the mouth of Ontario tunnel No. 2. In view of this report it will not be surprising if production be entirely stopped within a short time. At the Daly-Judge the entire equipment except the hoist has been electrified with power from the Snake Creek Power Co. The new Starrett pump has removed the water to the 1600-ft. level which opens the way for exploration of some rich orebodies which are supposed to exist at this depth but which have been inaccessible since a flood of water drove the men out without even time to rescue their tools.

Suit has been filed by the Beck Tunnel company against the Uncle Sam for $300,000, three times the value of ore alleged to have been illegally extracted by the defendant from plaintiff's ground. A temporary injunction has been granted. There is a theory held by some that the Uncle Sam apexes on the Beck Tunnel ground and, if this is the case, the suit may develop into one of extralateral rights. It is to be hoped that the action will not be a repetition of some of the bitter litigation which has proved so ruinous to some of the Tintic mines, notably the case of Eureka Hill *v.* Bullion Beck and Grand *v.* Mammoth.

In American Fork the old Silver Bell has been reorganized as the Eudora Bell and preparations are being made for active operation. The Salt Lake Copper Co. has received a new cable for its tramway and, as soon as the repairs are made, will commence shipping iron ore at the rate of about 200 tons per day to the Garfield smelter. An interesting point is about to be decided in mining law by the authorities at Washington, namely, whether work done by diamond or churn-drill can properly be applied toward the granting of a patent. In the case in question the application has passed the local authorities and the decision from Washington is being awaited with interest although there seems to be no reason why it should be adverse.

BUTTE, MONTANA

Smoke Cases Reopened. — Disposal of Tailing. — Butte Mines.

The so-called smoke case is apparently to be renewed with more vigor than ever this fall. Some months ago the Attorney General of the United States, acting on representation made to him by the farmers of the Deer Lodge valley, filed a suit against the Washoe Copper Co. alleging that vegetation was being destroyed by the fumes from the Washoe smelter at Anaconda. It is the same old case which was heard before Judge Hunt, but the findings in the case were not considered satisfactory, so the Government was induced to take up the matter. A dozen or more expert chemists are now in the Deer Lodge valley taking samples of the soil and examining the trees, vegetables, and grain for the purpose of ascertaining if the allegations of the farmers are correct. The Anaconda Copper Mining Co. which owns the Washoe smelter, has a number of experts on the scene also making tests and taking of testimony is expected to be even more extended than it was in the smoke case of more than one year ago. Considering the dryness of the season, the crops in the Deer Lodge valley never looked better which shows that the alleged poisonous gases and arsenic from the stack of the smelter are not as destructive to the grain and vegetation generally as represented by the ranchers. Whether the Attorney General, Mr. Wickersham, will personally appear in the case is not known, but it is believed he will in view of the fact that he is named in the complaint as the Government's attorney. The side of the Anaconda company will be represented by C. F. Kelley, chief counsel for the Amalgamated Copper Co., and several assistants.

The ranchers in the Jefferson valley are strongly protesting against the dumping of tailing from the Basin concentrator in the Jefferson river, and there is talk of action being brought to restrain the management of the Basin mill from what is alleged as polluting the water and making it unfit for domestic purposes. Should such action be taken it will seriously interfere with the working of the Butte & Superior mine and also the Davis Daly, as the ores from both mines are treated here. The recent decision of Federal Judge Dietrich of the Idaho district in practically deciding that the ranchers had no ground for complaint up to the present time as to the dumping of tailing in streams, but at the same time awarding the mine plaintiffs a verdict for $1 in all, will have an important bearing in the case of the Jefferson valley ranchers inasmuch as the cases are practically the same so far as the alleged pol-

lution of waters are concerned. It is said that the Jefferson valley ranchers have held consultations on the matter, and that one or more lawyers have been consulted with a view to seeking a remedy. As yet, however, no formal steps have been taken to bring the case before the courts but it is believed that in the immediate future a start will be made. Whether an attempt will be made to close down the concentrator or an agreement will be entered into to prevent such step is not known at the present time. The announcement is made that F. Agustus Heinze is coming to this city to look after the Davis Daly property and put the Colorado mine in shape for the commencement of shipments of ore to the Basin mill. It is stated that something like 39,415 shares defaulted on the first payment of the $1 assessment, but this was rather expected and it is now assured that after the second payment of 50c. is made September 20, some $561,594 will have been received into the treasury out of $600,000, which would have been realized if all the stockholders had paid the assessment. It is stated that within the next 30 days the Colorado ore will be going to the Basin concentrator at the rate of about 200 tons per day, but up to the present time no orders have been received in this city to prepare for active operations. A large amount of concentrating ore has been blocked out on the levels down to the 1700, sufficient, it is stated, to keep up shipments for a year or more.

Development is going along in the various mines of the Anaconda company without interruption. The new shaft in the Gagnon is down about 800 ft., while the sinking of the new Belmont shaft to connect with the Anaconda mine is down 1600 ft. The boom in North Butte the past week has been due to the highly encouraging reports coming from the mine. During July the company produced nearly 2,000,000 lb. of copper. It is reported, on what seems to be good authority, that ore of a high grade has been found which will bring the mine back to its old standing among the rich producers of the district. The Hudson mine in the Twin Bridges district which in the past has produced much valuable ore, has passed into the hands of New York capitalists who refuse to disclose their identity at the present time. An old mill known as the Iron Rod, on the west bank of the Jefferson river, is being remodeled and equipped with modern machinery and will handle the ore of the Hudson. The mill has not been operated for twenty years and the machinery is so crude that practically every part of it will have to be replaced.

BLACK HILLS, SOUTH DAKOTA

Non-Metallic Products.—Lithium Mining.—Dredge Operations.—Homestake.—U. S. Assay Office.

In the southern Black Hills, the neighborhood of Keystone, Custer, and Hill City, considerable activity is noticeable in the mining of non-metallic mineral products. Lithium minerals, mica, and wolframite are commanding the attention of many of the residents of that district. The mica industry is the principal feature at Custer. The Westinghouse company owns a number of properties and is deriving its entire mica supply from them. This company has mined mica at Custer for about four years, and is gradually adding to its holdings and bettering the equipment of them. Its deepest shaft is at the New York mine, five miles southwest of Custer. Within the past week the mica has been opened on the 300-ft. level, making this the deepest mica mine in the world. The quality is better than above, the mica being less brittle—probably due to the fact that this point is below the oxidizing effect of atmosphere and surface water. The New York mine is equipped with 500-hp. boilers, a steam-hoist, 150-kw. generator, electric driven air-compressor, and pumps; 70 to 80 men being employed in the production of 4000 lb. per week of sheet mica and a large tonnage of scrap. At two others of its properties the Westinghouse company has steam hoisting and compressing plants. At one the shaft is being rapidly sunk to the 200-ft. level, and at the other mining is being carried on at the 100. This latter mine is making a good production, but further development will be instituted as soon as the New York is opened on the 300. At to other properties the company is carrying on small development by hand methods.

Keystone is the centre of the mining of lithium minerals, the Etta mine and the Reinbold properties being the important producers. Amblygonite, a fluo-phosphate of lithium, containing 11% lithium and 48% phosphoric acid, is shipped regularly. The output of the Reinbold mine goes to the plant at Omaha, owned by Hermann Reinboid, while the material from the Etta mine, which is operated by Denis Henoult, is shipped to the chemical works on the Atlantic coast and to Germany. Along Rapid and Castle creeks, in the central Hills, placer mining has been conducted more vigorously than for many seasons past. The creek beds and bars have long been known to be valuable, but the water problem has been difficult of solution. The large bedrock flow has stopped many enterprising operators, and it is only within the past year or so that dredges have been suggested as a possible remedy. This season work is under way on the installation of a big dredge at a point a short distance above Mystic, on Castle creek, with the expectation that it will be in operation this fall. The results will be closely watched, many of the operators contending that the bedrock is too rough and hard to permit satisfactory dredging. Hydraulicking and sluicing are being carried on at a number of points, the biggest plant being at Pactola, on Rapid creek.

The Homestake employees' aid fund became operative August 1, business being started by a deposit of $1000, the gift of the Hearst Mercantile Co., operator of the biggest store in Lead. The fund will be maintained by assessing each employee one dollar per month, which will be deducted from his wages. In addition to this the Homestake company agrees to contribute $1000 per month. The rules under which the fund will be disbursed call for a payment on account of disability through accident or sickness, one dollar per day, the sick benefit commencing after the sixth day. Payment of this amount will be made for six months, with a privilege given the board of directors to continue payments beyond that limit. For the loss of both hands, both feet, both eyes, fracture or dislocation of the spine, causing total disability, the fund will pay $800. For the loss of one hand, one foot, or one eye, $400. The death benefit is $800, payable for death from accident received while at labor for the company, or from sickness. Very stringent rules are laid down for the purpose of suppressing drunkenness and immorality. No benefits will be paid for accidents due directly or indirectly to intoxication, the idea being to thus protect the fellow worker of the intoxicated man from danger or accidents that might be caused by the carelessness of the man who has been dissipating. The board of directors consists of five members, elected for one year. For the present year they are: J. W. Freeman, chairman, chief physician and surgeon; Richard Blackstone, assistant superintendent of the company; W. S. O'Brien, mine foreman; A. J. Clark, superintendent of cyanide mills; and J. A. Spargo, master mechanic. T. J. Grier, superintendent of the Homestake, is treasurer of the fund. The Homestake company furnishes, without charge, such office room, stationery, and clerical help as is necessary.

The United States assay office at Deadwood now handles the entire output of the Black Hills mills. Commencing August 11 the Homestake company turns over its entire output to this office. This means a material increase in the business of the office, placing it, in value of bullion handled, far ahead of all Western offices but Seattle. The Homestake company had always insisted that payment for its bullion be made in New York funds, and until recently the Deadwood office was not in shape to meet this requirement. During the spring E. W. Martin, Congressman from Deadwood, was instrumental in securing the opening of an account with the assistant treasurer of the United States at New York, and upon the Homestake being notified that payment could be made by check against this account, arrangements were made for shipping the entire product of the company to the Deadwood office.

LOS ANGELES, CALIFORNIA

The Oil Industry.—Clara Consolidated.—Activity in Iron.

The Western Oil Producers' Association was organized here on the evening of August 25. Over 100 oil operators were present at the meeting but the expected delegation from San Francisco did not appear. Chiefly on this account an attempt was made to postpone action. This was partly successful in that the association did not commit itself to any policy. After effecting an organization and adopting the by-laws, following much spirited debate, it was decided to call another meeting for next week, thus giving the northern men time to be heard. Only 54 names were placed on the membership roll, but it is hoped that many others may sign before the next meeting. Permanent officers were not elected. An attempt to merge the next meeting with the one called at Bakersfield for September 4 was defeated. The by-laws as adopted provide that it shall be the purpose of the association to unite the oil operators of California and the West for the protection and advancement of the oil industry; to secure legislation that will govern the disposition of public lands containing oil in a manner just and equitable alike to the operator and the Government; and to devise ways and means for effectually advancing the common interests of oil men by all legitimate methods. Contrary to views expressed at the first meeting, there was demonstrated at this a decided opposition to any form of conservation of oil lands and to the disposal of them by any method other than location and discovery as at present. It is probable that the resolution to be presented at the meeting of the American Mining Congress will embrace a plan for the betterment of conditions in which conservation will not be mentioned.

The American Petroleum Co., operating chiefly in the Coalinga field, has at present 35 producing wells, yielding a total of 11,000 bbl. per day. Fourteen additional are being drilled. The average depth of all wells is 2000 ft. The payroll amounts to about $25,000 per month. The American Oilfields Co. has six producing wells in the Midway field, producing 25,000 bbl. per day. Eighteen new wells are being drilled. Well No. 79 is now flowing at the rate of 20,000 bbl. per day. No. 68 is doing about 4000 bbl. The payroll amounts to $25,000 per month. The Lakeview gusher of the Union Oil Co. in the Maricopa-Sunset field is now flowing at the rate of 20,000 bbl. per day. This company has 29 other operating wells in this district flowing a total of 10,000 bbl. The next largest production of this company is from the Santa Maria field, where 90 wells are yielding 12,000 bbl. per day. The smallest production is from the Ventura field where 115 wells are yielding only 500 bbl. per day. The Union company has just abandoned its Brashear No. 1 well, situated five miles west of Los Angeles. This well is the deepest in California, having been drilled to a depth of 5665 ft. The outfit has been moved to the Fullerton field, where a well about 4500 ft. deep will be drilled on the Baster-Chury lease.

At the property of the Clara Consolidated Gold & Copper Mining Co., Swansea, Arizona, the installation of the large steam-hoist over shaft No. 5 has been completed. This shaft is now 200 ft. deep and sinking is being rushed. It is figured that 60 ft. more will put the shaft in the orebody demonstrated by the drill holes. All the surface construction work has been completed and the construction crews laid off. The mine and smelter are assuming rapidly a normal operating basis. The Federal Development Co. and the Noble Electric Steel Co. are active in the Minaret district, Madera county, California. Both companies have spent quite a large amount of money in exploratory work and there is every indication that they will be working on a large scale before many months. It is reported also that the Guggenheims and Charles M. Schwab have been quietly securing options and making investigations in several localities. The activity of the Noble company is traceable to the recent successful run of the Heroult electrical smelting furnace where contracts have been let to furnish equipment for four more units.

JARBIDGE, NEVADA

Lack of Capital. — New Discoveries. — True Fissure Group. — Shadow. — Map of Claims.

This camp continues to show a steady advancement regardless of the fact that there is practically no money coming in to it for development. The payroll is abnormally small considering the size of the camp, but the lessees and prospectors are doing their best to prospect the ground. They are opening new veins and obtaining good assays in many places, and when the money does come into the camp there will be an abundance of good prospects ready for development. The latest discovery was made two days ago about eight miles southeast of town on what is called the fifth crater, near the head of the river, when Buys & Franklin opened a vein five feet wide with a streak of high-grade quartz on the hanging wall. This is apparently the same vein that has been opened in the third and fourth craters, and in the third crater on the Third Peak No. 1, belonging to the Twin Fissure Gold Mining Co. This vein has been

Rim Rock near Jarbidge.

opened in several places for the entire length of the claim, showing a large body of quartz from which some good assays have been obtained. Near the north end of this claim, R. F. Harder and Bishop Norman have opened a spur-vein five feet wide from which ore assaying $240 per ton has been taken. Three assays were obtained on ore from the Arkansas claim which has been bonded to a representative of Eastern capital. The vein has been traced southwest into Snowslide gulch, crossing the DeWitt and La Veda claims, and through the Little Mud, on which it is 10 to 15 ft. wide. The latter group has been bonded by Colorado men. An adjoining property known as the Shadow has also been bonded by Denver interests. The Shadow vein has been traced north through the Red Rooster claim in Gorge gulch and is supposed to be the same vein on which the Winkler discovery was made. The latter ground, on which the finest showing in the camp has been made, is still tied up in the courts by the several conflicting interests.

The Rock Creek and It claims north of the Bluster have been bonded and considerable trenching has been done to find the vein in place, but so far only rich float has been found. The Success group adjoining the It, Bluster, and Shovel claims has been bonded to Colorado interests. This property is known to be crossed by several veins, the Pick & Shovel and others. A new vein has recently been opened

near the Bluster on the south and the Success claim which is five to six feet wide. The 4 M lessees have a carload of ore ready for shipment and are finishing a road from their camp to town in order to ship at an early date. This ore is expected to yield high results.

W. W. Williams, who has a bond on the Red Bird and Buffy claims just east of the Pavlak has a force of men at work prospecting and has opened two veins which pan well. Theodore Parks has nad his Jarbidge Wonder No. 1 and No. 2 and the Minnie claims near Snowslide gulch surveyed and is prospecting preparatory to developing the ground. The surface shows considerable good float and he has found two veins in place. W. W. Fisk has completed a claim map of the camp, showing the location of over 500 of the more important claims. The Jarbidge Commercial Club has been organized to promote the interest of the camp.

NEW YORK

Dull Market Conditions. — Anaconda Sues Butte-Ballaklava. — Ohio Copper Financed. — El Rayo-Dolores Consolidation.

If one were to be guided by the dominant note in all financial comment of the day, emanating throughout the East, he would almost come to think the Eastern slope of the Appalachian range a productive region. Never a prodigal son of modern days has been more soundly lectured on the manifold sins of extravagance than has been our great producing West scolded by the makers and venders of securities. However, the producer is learning some lessons in independence which he will be slow to forget and Wall Street is to learn a primary chapter in corporate honesty, and is to come to a realization that high finance and crookedness are synonymous terms now in the minds of the real people, who are taking the real dollars out of the mines, the corn fields, and the wheat fields of the country, none of which are on the Atlantic seaboard. The lesson for the East is to be a bitter one, the opponents of concentrated financial power are playing the highest trump card they hold, that of letting the securities market alone. In due course our leaders of corporate enterprises will learn that the one real way to win the confidence of the general public is to deserve it. Awe is not so popular as it once was, the iconoclast rather has the public sympathy with him. The markets are deadly dull, it is the vacation season, and many vacations have been lengthened because of lack of business. Barring such slowing down of operations as has taken place at various copper properties where production is curtailed, nearly every mining centre reports great activity. The Esperanza, Ltd., at El Oro, reports the hoisting of more ore than ever before. Cobalt is again making a record output. Porcupine is making good according to local authority. The Nevada camps—Goldfield, Tonopah, and Fairview—are witnessing much new work, but markets lag. The figures recently compiled by the British Government, enumerating the miners throughout the world, give some idea of the great strides the mining industry has made in the past twenty years. In round numbers there are six million miners in the world; all of the varied manufacturing industries of the United States employ in the aggregate only about the same number; in 1894 the number engaged in mining was calculated at 3,130,000. In this country the ratio of increase has been greatest; in 1892 our annual mineral production was $648,000,000, in 1909 it was $1,900,000,000, or almost treble.

A story given out as authentic, to the effect that the Phelps-Dodge interests had purchased control of the Imperial Copper Co. from the Development Company of America lacks confirmation here. On the other hand, it is stated that the Development Company of America recently bought the McCabe mine in Yavapai county, Arizona, from the Ideal Mining Co. The McCabe property was the medium of a most spectacular promotion during the time the property was in the hands of the Model Gold Co. Monthly dividends were paid, bullion bars were placed on exhibit, which were said to show careless melting and upon close examination to reveal the milled edges and mottoes of minted coin. Shares reached a high mark of $15 per share, which was a valuation of $45,000,000 for the property. Federal authorities pricked the bubble by arresting the promoters for fraudulent use of the mails.

The bringing of an action by the Anaconda against the Butte-Ballaklava, similar to the action brought against Tuolumne, is bringing down condemnation upon the Anaconda officials, who are now accused of making unfair use of the courts to sustain alleged apex rights, even as Heinze did against the Amalgamated, in the days when Montana was divided into 'kerosene or pickles.' The suit against Butte-Ballaklava claims some $1,100,000 for ore wrongfully extracted and asks for an injunction restraining further operations. The injunction will be heard early in September. Mr. Heinze has just returned to New York from a stay on the continent, during which he says he financed Ohio Copper, by the sale of $1,000,000 of Ohio bonds, thus avoiding the necessity of selling the timber lands of the United Copper Co. in British Columbia; this step was considered as a possible alternative.

Dispatches state that street laborers have opened a 10-ft. vein of exceedingly rich copper ore almost in the centre of Reno. The find was made at a depth of 10 ft. below the surface and is said to be apparently an apex of a permanent formation. The Calaveras Copper Co., of Copperopolis, controlled by Boston interests, has voted to reduce the capital stock from $5,000,000 to $2,500,000 by reducing the number of shares from 1,000,000 to 500,000. The merger of the El Rayo Mines Co. and the Dolores Mines Co. with the Mines Company of America will be completed about the middle of September. The par value of Mines Company of America is to be increased from $1 per share to $10 per share and Dolores will then be exchanged share for share, or on a basis of one share of Dolores for ten shares of the old stock of the Mines Company of America. El Rayo will be exchanged on a basis of ten shares of El Rayo for seven shares of the new stock of the Mines Company of America, equivalent to one share of El Rayo for seven shares of old stock of the Mines Company. Mines Company of America and Dolores are controlled by a prominent group of capitalists of New York and Chicago, including John J. Mitchell, of the Illinois Trust & Savings Bank of Chicago; Isaac L. Ellwood, of De Kalb, Illinois; John Lambert, of the Illinois Steel Co.; and Harry S. Black, of New York, who is connected with the Fuller Construction Co. and the United States Realty & Improvement Co. Mines Company of America is to be listed on the New York Stock Exchange as soon as the consolidation is completed.

The New York, Honduras & Rosario Mining Co. is to pay dividends quarterly hereafter instead of monthly as has been the custom in the past. The company has distributed 1% monthly for some time. Its properties are at San Juancito, Honduras. The Palmilla Milling Co., a subsidiary of the Alvarado Consolidated which is working the Palmilla mine near Parral, Chihuahua, made famous by Pedro Alvarado, held its annual meeting the last of August. The Palmilla mine was one of the most talked of pieces of mining property on the American continent, while it was worked by the former owner, at one time a peon, and of whom many extravagant tales were told. Since it was taken over by Boston interests, the new promotion, based on the property, has seemed to have an uphill time.

The first annual report of the Sierra Consolidated Mines Co. has just been sent out. This company, which is controlled by the Cole-Ryan interests, took over the greater part of the properties controlled by W. C. Greene and his Greene Gold Silver Co., before the downfall of Mr. Greene and the collapse of the latter company. One of the most valuable concessions taken over was a very large tract of timber land, from which the company is securing all of its mine timbers and lumber for building purposes. A 300-hp. electric generating plant is being installed about six miles from Ocampo, in the heart of the Duranzo timber tract. The company now owns a mill at El Salto which can be run during the rainy season by water-power; later a new mill with a considerably increased capacity is to be erected on the same site.

General Mining News

ALASKA

On August 29 the Alaska Mexican Gold Mining Co. paid a dividend of 30c. per share; the Alaska United Gold Mining Co. one of 10c.; and the Alaska Treadwell Gold Mining Co. $1 per share.

ARIZONA

COCHISE COUNTY

The third shift has been started in the Leadville shaft of the California & Paradise company at Paradise.——On the Duncan group drifts have been started along the hanging wall on ore that assays 14% lead with $3 to $8 gold per ton.——The drift on the Taylor property is in 70 ft. on the vein which contains a fair percentage of copper.

GILA COUNTY

(Special Correspondence).—Work at the Miami mine underground is entirely as yet for development and is being concentrated on preparing the necessary drifts for haulage purposes.——Development at the Inspiration camp is continuing with the same rapidity that has characterized operations there in the past. The Colorado shaft is at a depth of 350 ft. and will be continued for another 100 ft. or so to bring it to the same elevation as the main extraction adit. The testing plant which is being built a few hundred feet south of the Joe Bush shaft is well under way, some of the tables being already in place and the larger parts of the crushing machinery ready to set up. ——A new field of operations has been opened at the Warrior camp as a result of the discovery of a new block of high-grade ore in the eastern workings of the mine.

MOHAVE COUNTY

Lewis Rothe and John Oleson who are operating a group of claims in the Secret Pass district have opened a number of rich stringers in the big vein that crosses the property.——The shaft at the London mine is to be sunk an additional 100 ft. and the vein prospected from that level. ——The water at the Tennessee mine is under control and work has been started retimbering the old shaft.

PINAL COUNTY

(Special Correspondence).—The work of channel diversion for the protection of the stock pile and the railroad yards at the Ray Consolidated mine at Ray is progressing satisfactorily. The stock pile protection is complete and work on the yards is well along. The company is gradually putting into operation a scheme for the comfortable housing of its employees. The arrangement whereby the Mexicans have quarters to themselves is working well, and it is planned eventually to have separate quarters for the Americans, Mexicans, Indians, and others. The surface buildings which include dormatories and a guest house, are nearing completion. The present payroll shows 30% white and 70% Mexican, Spanish, and Indian labor in and about the mine. At Ray there are between 700 and 750 men engaged in underground and surface work connected with mining. The average advance made in driving is a little more than 3 ft. per machine per shift, and about 1000 tons of ore per day is being placed on the stock pile. Ore that has been coming from the mine has been crushed in a temporary plant; however, one of the large Gates crushers has just arrived on the ground and this will be moved to the shaft and installed at once. In order to facilitate the development of the mine and provide for a larger tonnage than was at first figured on, a new shaft has been started above the town of Ray. It was first planned to install a mill of about 5000 tons per day capacity, and the mine development was planned accordingly. However, the mill as now going in, will be able to handle from 8000 to 10,000 tons per day.

Ray, August 27.

YAVAPAI COUNTY

(Special Correspondence).—The Arizona Copper Belt Mining Co., operating sixteen miles east of Wickenburg, recently made a test shipment to the Humboldt smelter. The ore was taken from adit A on the Wren group which is under development, and was valued from $80 to $120 per ton in gold, silver, and copper. No attempt has been made to stope any from the shoot which is 50 ft. long and 3 to 5 ft. wide. Work at present is confined to the adit but a shaft will soon be started and later a 10-stamp concentrating mill will be erected. By fall enough ore will be blocked out to keep the mill busy for some time. F. A. Crampton is in charge.——The Arizona Power Co. is making preparations to construct a loop line for electrical transmission into Prescott through Jerome, reaching that point by building from Fossil creek up the Verde River valley. This line will make it practically impossible for the Prescott district to be left without power or light as has happened occasionally in the past.——The new electrical equipment of the Haynes Copper Co., at Jerome, has arrived, and is being installed as rapidly as possible. Development will be resumed as soon as the big pump is in shape to handle the water.——The stockholders of the Ideal Mining & Development Co., of McCabe, have ratified the sale of the Ideal and Gladstone mines to F. M. Murphy of Prescott. John L. Davis remains in charge of the properties.

Prescott, August 29.

On a test run of 1000 lb. at the experimental mill of the Big Butte Mining Co., on the Hassayampa river below Walnut Grove, a concentrate assaying 36 oz. gold per ton was obtained. Forest McKinley is manager.

CALIFORNIA

MARIPOSA COUNTY

The American Eagles mine near Exchequer has been purchased by J. E. Meyer & Co., of Los Angeles, and the 150-ft. adit will be driven to tap the vein which is 50 ft. wide on the surface. The ore is free milling and the new owners propose to erect an electrically equipped mill.

NEVADA COUNTY

The Red Ledge Gold Mining Co., has been incorporated to operate the Red Ledge mine in the Washington district. ——The owners of the Oustomah mine, near Nevada City, who have been operating the mine since the recent bond on the property expired, have opened a shoot of free-milling ore on the 900-ft. level.——The construction of the Fairview mill is nearly complete and the management expects to have the stamps dropping by the middle of the month. While the work on the mill has been under way over 400 ft. of drifts have been driven on the shoot and several raises run blocking out a large amount of ore.——The St. Gothard Gold Mining Co. which operates the Delhi mine, at Columbia Hill, is to sink the shaft an additional 200 ft. the bottom now being 400 ft. below the adit-level. While this work is in progress the 20-stamp mill will be idle.—— The old Davis adit on the Pickle ranch is being cleaned out and retimbered, and will be driven to tap the Blue Lead channel.

SHASTA COUNTY

(Special Correspondence).—The Great Western Gold Co., which owns the Afterthought mine at Ingot, has 15 men at work at the property and is expected to increase this force considerably within the next two months. A new shoot about six feet wide has been opened recently.——The Western Exploration Co. has assumed control of the Milkmaid mine at French Gulch and will commence development in the lower levels.

Redding, August 29.

SIERRA COUNTY

(Special Correspondence).—During the month of August a number of properties have been opened around Sierra City. The Primrose mine in Wild Hog canyon, seven miles northwest of this city, has been reopened by DuRay Smith, of San Francisco, and a large force of men is at work clearing out the mine and getting the 10-stamp mill in shape to start. This mine was located in 1853.——The Empire Gold Valley eleven miles north of Sierra City has been reopened. The shaft is being repaired and ore is being blocked out preparatory to starting the 20-stamp mill on

the property. Curtis Locklin is superintendent.——The Cogley brothers have been reopening the St. Louis mine, three miles from Sierra City, and have a large body of ore blocked out.——The Cleveland mine, which has just finished one mill-run, has a crew of men breaking ore for another.——The Standard mine is crushing ore in the custom mill at Downieville. The ore is rich arsenical pyrite and is from the same vein that $17,000 was taken from a few weeks ago.——The Chipps will have the new 10-stamp mill started early in September and a force of men is now busy getting out ore for the initial run.——The Sierra Buttes mine is looking better than it has for years. All work is being done through No. 6 and No. 7 adits. At the mill the ore-bins are being repaired preparatory to continuous operation.——C. R. Thompson and associates have taken a bond on all the holdings of the Lee brothers, at the head of Black's canyon. A shaft is to be sunk on the vein for 200 ft. and drifts run to develop the property. Three shifts are working.——At the Colombo the new lower adit has been started and will be driven 1000 ft. to cut the Colombo vein.——There has been a small stampede to the old camp of Meadow Lake twenty miles east of Sierra City. There are about 100 men in the camp, the ores of which are rebellious and must be shipped to smelter. Clutt & Ramsey are making up a shipment of rich galena ore containing gold, silver, and copper. Campean is shipping the same class of ore to smelters and Cook & Clark have rich copper ore in the shaft on their property. The vein is 10 ft. wide. The Porter brothers, of Denver, are erecting a cyanide plant on the old Hartley property.

Sierra City, August 27.

TUOLUMNE COUNTY

(Special Correspondence).—The mining of gold-bearing gravel has begun at the property of the Gold Ship Mining Co., near Groveland. Sluices are to be laid at once and grading for the mill will be commenced as soon as the work of putting up an electric power line is well under way. It is the company's intention to install more machinery in the near future.——Development is being carried on with renewed energy at the Mohican mine and it is reported that an important discovery has recently been made. The overhauling of the mill has been completed, new mortar blocks put in, and a new ore-bin erected.——Dredging operations were started this week at the gravel property of the Tuolumne Consolidated Co., near Phoenix lake. It is expected that approximately 2000 cu. yd. per day will be handled.——The operators of the Dutch & Sweeney mines expect the arrival soon of 6250 ft. of 6-in. pipe, which will be used to convey water from the ditch on the Harvard hill to the concrete reservoir on the Dutch claim. It is expected that complete operations will be resumed within a few weeks. The drift on the 400-ft. level of the Dutch is 500 ft. long and will be driven to connect with the Sweeney shaft where a rich orebody was penetrated.——At the Tarantula mine, of which T. C. Crawford, of London, is the principal owner, a crew of men is grading for a 20-stamp mill, the machinery for which is due to arrive soon. It is the intention to eventually increase the crushing plant to 100 stamps. Approximately five miles of adits, drifts, and cross-cuts have been driven and development is still going on uninterruptedly.

Tuolumne, August 29.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence).—A body of mixed ore and quartz 2 ft. wide has been uncovered in the breast of the adit being driven on the Big Indian vein. Samples assay 2.5 and 4.4 oz. gold per ton.——J. G. Hite has erected a small plant below the Capital mill and the tailing is being treated. About 10 tons per day is being handled.——A. H. Colburn has taken a bond and lease upon the Annex and Pinion claims on Alpine mountain, the bond calling for $15,000. The Annex is an extension to the Sporting Times which has been extensively developed.——Stephens brothers shipped a carload of lead from the Mendota mill last week that brought a settlement of 60% lead and 68 oz. silver per ton.——A 50 and 25-hp. motor arrived last week for the Lombard mine. It has been decided to double the capacity of the 25-ton mill, while machine-drills will be brought into use in driving level No. 4. K. Seemann is manager.

Georgetown, August 27.

GILPIN COUNTY

(Special Correspondence).—Work on the Frontenac mill is being hurried, a force of 20 men being employed. It is hoped to have this plant in operation within 60 days.——The New York mill resumed operations last week after a shut-down of four weeks due to the dam being washed away. A large amount of ore has accumulated and it will be necessary to keep the machinery in operation night and day for some time.——The road leading to the National mine has been repaired and the new machinery is now being delivered. McKay & Co. are operating under lease.——A small mill is in course of construction below the dumps of the Buell mine. The equipment will consist of crusher, four bumping tables, rolls, and three Wilfley tables. Ore is to be treated that is worth $2.50 to $3.50 per ton. Smith & Sydow are the operators.

Gregory-Buell Mine.

Central City, August 26.

TELLER COUNTY

M. B. Rapp, leasing on the Dante No. 2, has opened a 5-ft. shoot on the 600-ft. level and is shipping a carload of ore per day that averages one ounce of gold per ton.——A compromise has been made between the Hiawatha and El Paso companies regarding the orebody recently opened on the Ida May claim, the ore being divided between the two companies.——W. Horn and associates have opened a new shoot on their lease on the Isabella property and are preparing a shipment of ore that assays $200 per ton.——A carload of smelting ore assaying $45 per ton was forwarded recently from the Lucky Gus claim.——An orebody assaying $40 to $180 per ton has been opened on the seventh level of the Chickenhawk property, and a shipment is to be forwarded at once.——A number of water courses which drain some of the shafts on Beacon hill have been tapped by the Roosevelt tunnel and the water is being slowly lowered in the mine workings. Within the last week the water in the Banner shaft has gone down 10 ft.——A hoist, compressor, and motor are being installed at the Mabel M. shaft.——The Western Investment Co. has commenced work on the Ophir mine upon which it has a long lease.

IDAHO

SHOSHONE COUNTY

The Interstate Mining Co., composed of Duluth and Minneapolis capitalists, has been organized under the laws of Arizona with 250,000 shares of stock at a par value of $10 each, to develop a number of claims near the Hercules mine at Burke. Gus. Carlson, of Hibbing, Minnesota, is president, and H. G. Rodearmel, of Minneapolis, vice-president. Twenty-five thousand shares of stock have been disposed of to provide capital for preliminary work.

A modern bunk-house is to be started and the company has already awarded a contract for the cutting of 500,000 ft. of the heavy timber on its claim for mining purposes. ——Thomas G. Kennedy, secretary and manager of the Missoula Copper Co., reports a discovery of ore on the Gold Hunter property near Mullan. Eight feet of galena was opened by cross-cut from the bottom of the shaft, sunk from the lower level.——Reports were submitted to stockholders of the Black Horse Mining Co., at Wallace, that the 150-ton mill will be in operation in 60 days.——The Iron Mountain Tunnel Co. has discovered a rich galena outcrop near the top of the mountain on the Iron Mountain claim. The outcrop is 3 ft. wide and assays run 50% lead and 30 oz. silver per ton. The new orebody can be reached by extending the adit on the 1600-ft. level for 500 ft. Heretofore, operations on the Iron Mountain property have been confined to one orebody 550 ft. long though recently the management has discovered several new shoots. The mill is being increased to 150-ton capacity.

MISSOURI

JASPER COUNTY

(Special Correspondence).—The largest mining deal for several weeks was last week closed when the Mrs. D. V. Scholl tract, at Porto Rico, was sold for a large figure to an Oklahoma company. The land has been well developed by five drill-holes showing ore at 240 ft, where the mineral runs 8 to 20% zinc, with a 15-ft. face. This makes one of the richest sheet ground mines in the district.——One of the richest mines now at work in the district is the Green Dog, where a rich discovery was recently reported. As work advances the ore grows more abundant so that for two weeks the company has turned in a ton of concentrate per working hour.——Another promising producer is the Lima mine in the South Carterville camp, where two recent finds have been important. A drill rig put in an old abandoned shaft which had been sunk to 100 ft., struck a rich vein of ore after only a few feet of operation. The ore was said to run 15 to 20%, and continued to 121 ft.——On an adjoining lease the new Tom Sawyer mill has started operations and is working on a rich deposit at 230 ft., where the ore runs 15%.——On the Centre Creek land, at Webb City, the Mercedes company is planning to take up a stope of 20 ft. extending from 170 to 190 ft. Operations were conducted at 170 ft. and a high drift was worked. There is still ore beneath the 190-ft. level.——In the extreme northern field there are as promising developments as can be found in the entire district. The land first developed by the Quick Seven Co. is yielding a high grade of ore, mainly zincblende, from 55 to 170 ft., with the cuttings averaging 10%. The remarkably high face and the richness of the ore attracted wide attention and brought numerous operators into the field, so that there are now in the vicinity a number of companies operating large mills.——To the west of Neck City, the Cliffwood company is operating steadily on the new mill, producing last week 80 tons of ore assaying over 62%.——In the main Joplin camp several important discoveries have been made. In the vicinity of Toms Station, the deepest find, so far made there, was found by S. L. Bradley on a lease of the General Zinc Co., at a depth of 251 ft. Other holes will be sunk.——The Granby company, the largest land-holding company in the district, has sunk a shaft in Poor Man's gulch and has cut a good run of ore from 105 to 120 ft. The 15-ft. face yielded 5 to 7% ore with no showing of lead. This land was one of the richest of the shallow mining camps in the early days, the place deriving its name from this source. The operations were then mere gouges in rich lead pockets.

Joplin, August 27.

MONTANA

GRANITE COUNTY

(Special Correspondence).—The Sunday mine, situated near Princeton, has passed to the control of Arthur V. Corry, of Butte, who is putting up a small cyanide plant to treat a dump of tailing that accumulated some years ago. It is estimated this dump material contains $13 to $15 per ton. The mine has been leased to Allen & Co., of Butte, who are to reopen it.——L. U. Loomis is operating the Shakespeare mine and the Royal Gold Mountain. He is installing a hoist and air-compressor, and has let a contract for 2000 cords of wood. This is twelve miles from Philipsburg.

Philipsburg, August 26.

JEFFERSON COUNTY

(Special Correspondence).—The Boston & Alta Copper Co., M. L. Hewitt, manager, is developing and exploring below the old workings in the Alta mine, at Corbin. Within the last year a new 2-compartment shaft has been sunk 700 ft. in rhyolite, close to the portal of the old Alta adit. A cross-cut has been driven 500 ft. from the 675-ft. station of the new shaft, opening a vein which contains good ore. It is not certain that this is the Alta vein. This cross-cut is tapping the orebodies about 100 ft. below the lowest of the old workings. The Alta vein is on the contact of granite and rhyolite, and has an average width of 40 ft. The ore in the higher levels yielded silver and lead, but at greater depth it became a copper-iron sulphide, containing gold, silver, and copper, the greater value being in copper. The old adit, through which the ore was hauled in early days, consists of a 600-ft. cross-cut, and a 3300-ft. drift. The property is equipped with a Nordberg electric-driven air-compressor, and a hoist operated by compressed air. The electric power is supplied at the company's plant in Prickly Pear valley. No ore is being shipped at present. A force of 20 men is employed.——The Corbin-Pennsylvania Mining Co. is developing a property which contains an extension of the Alta zone. A 150-ft. shaft has been sunk between two veins, which are 250 ft. apart. One of these is the Alta, which on this property is 18 ft. wide, and on a contact between a granite and porphyritic rock; the other vein is 10 ft. wide, and in granite. Both veins strike northeast, and have a dip of about 70°. The ore is composed of chalcopyrite and bornite, accompanied by some silver. One car of hand-sorted ore, shipped in 1902, sampled 9% copper, and 29 oz. silver per ton. H. E. Emerson, manager for the Boston & Corbin Co., has charge of this development; H. M. Brooks, of Corbin, is secretary of the company.

Corbin, August 26.

NEVADA

ESMERALDA COUNTY

Two new bodies of commercial ore have been opened in the Victor workings of the C. O. D. Consolidated, at Goldfield, at a depth of 400 ft. and development has been started to determine the extent of the shoot.——The workings of the Vinegarone claim of the Jumbo Extension are being sampled and surveyed that the engineers representing the owners may have a complete record of the underground development.——The engine and compressor recently purchased for the Phoenix lease, at Rawhide, has arrived at the mine and will be installed as rapidly as possible.——The Queen mill has completed a run on 114 tons of ore from the Grutt-Balloon Hill lease cleaning up about 700 lb. of amalgam.

NYE COUNTY

(Special Correspondence).—The Tonopah mines are shipping about 7750 tons of ore per week, valued at approximately $193,700. It is expected that the total production for August will approximate $850,000, said to be the largest output for any month in the history of the camp. Tonopah of Nevada is producing 3500 tons per week; Belmont, 1865 tons; Montana, 1050 tons; Tonopah Extension, 840 tons; West End, 325 tons; MacNamara, 120 tons; and Midway, 50 tons.——The enlargement of the Belmont shaft from two to three compartments has been completed within 150 ft. of surface, and it is expected to complete the work within 60 days.——Extensive exploration is under way in the north portion of Midway, with work centered at the 435 and 1035-ft. points. Ore is being stoped on the south vein, above the 235-ft. level, on the No. 3 vein, 335-

ft. level, and on the Brougher vein, at the 435-ft. level. From the latter point a north cross-cut is being driven in an endeavor to pick up new veins in an entirely new portion of the mine.——The Steen lease on Big Four, at Manhattan, is arranging to sink a 500-ft. shaft near the old workings. Under the terms of the lease this shaft must be completed before any ore is extracted.——The Peterson mill is running steadily on custom ore.——The Wilson lessees on Wolftone Extension are making weekly shipments of bullion to Tonopah.——John Kelley has acquired the Allison lease and is thoroughly prospecting the ground. ——The Round Mountain Mining Co., operating at Round Mountain, has declared a dividend of 4c. per share, payable September 25, to stockholders of record September 20.

Tonopah, August 27.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence).—The pipe-line of the Helen Mining Co. up Whitewater creek is completed and a small force is engaged in finishing the details of power station. The plant will probably be started within two weeks.—— Grading for the mill at the Deadwood mines is nearly completed. The shaft crew is making good progress. Driving continues on the 400-ft. level, the south face of which is in fine ore from which 75 tons were added to the broken reserve the past week.——At the Socorro mines 1292 tons of ore were milled during the week and 12 bars of bullion shipped. This company is now producing approximately 100 lb. of refined gold and silver every 24 hours as well as large quantities of high-grade concentrate. Additional zinc-boxes are soon to be installed as an essential for the proper precipitation of the increased value in the solutions. Development in the sixth or lowest level shows a continuance both east and west of the large vein.——The winze of the Enterprise Mining Co. below the second level continues in a fair grade of ore. A contract has been let for driving a cross-cut to the foot-wall on No. 5 level.——The Oaks company acquired other claims and added to the tunnel group during the week.

Mogollon, August 26.

UTAH

JUAB COUNTY

James Sorenson and J. W. Knight have secured a lease on the Salvador property in the Eureka district and will install a cyanide plant to treat the low-grade ore.——Sinking is continued at the Iron Blossom, the shaft being down over 1760 ft. About 80 tons of ore per day is being shipped from the 500-ft. level of the No. 1 workings.——Work is to be resumed in the Tintic Gladiator incline shaft, which is down 100 ft. The ground is east of the Iron Blossom, and a good surface prospect has been opened.——The Chief Consolidated has opened a new shoot in the main drift on the 1400-ft. level.

SUMMIT COUNTY

It is reported that a body of ore has been opened on the 1900-ft. level of the Daly West property at Park City, conditions on that level showing a general improvement. This shoot has been cut on the 1700, 1800, and 1900-ft. levels and a contract has been let to drive a cross-cut to it on the 2100. Despite continued rumors of curtailment of forces the company is laying in large supplies on mining timbers and coal.

CANADA

BRITISH COLUMBIA

(Special Correspondence).—Two gold bars were shipped from the Nugget mine in the Nelson district during the past week, valued at $10,000. On the Golden Fawn property, which adjoins the Nugget, a vein four feet wide, giving assays up to $200 per ton, is being developed. Two adits are being driven on the property, one of which is in 100 and the other 200 ft.——The Eureka mine, on Eagle creek, which has been under development for the past couple of years, will begin shipping to the Trail smelter in a week or two. It is the intention to make regular shipments.——The zinc-lead miners of this district note with interest that the Dominion Government has started the experimental work in zinc smelting, for which $50,000 was recently appropriated. A small plant has been built at Ottawa for some preliminary experiments, though it is highly probable that the final work will be carried out at the Nelson smelter.——The Pacific Exploration Co. is planning to develop the power of the Pend Oreille river near its confluence with the Columbia. Just below the mouth of Priest river the Government Reclamation Service made some measurements, the lowest of which was 5419 cu. ft. per second, in February 1905, the next lowest figure was 7852 cu. ft. per second, some 30 days previously. It is possible to obtain a head of 40 to 53 ft. along the Pend Oreille at this point. The International Electric Co., in which it is supposed the Canadian Pacific Railway Co. is interested, purposes to use 4000 cu. ft. per second from the Pend Oreille at a point near the Salmon river, under a head of 53 ft. Assuming a switchboard output of 70%, this would permit of the delivery of 12,720 kw., but it is not probable that more than 5000 kw. will be developed to start with. This power could be used with advantage in the Sheep Creek district, the Pend Oreille valley, Metaline, Chewelah, and Orient.——Toronto capitalists have bought an interest in the Evans group, St. Marys district, for $10,000. The ore contains copper, gold, silver, and nickle, and the formation is said to be similar to that in the Sudbury nickle district.——At a regular meeting of the Le Roi Mining Co. held in London, August 18, it was decided to go into liquidation; A. J. McMillan, erstwhile managing director of the company at Rossland, to be liquidator.—— A bond has been taken on the old Waterloo and Fontenroy property, Camp McKinney, by Victoria capitalists.——The contract for an extension of the Kettle Valley railway has been let to a Seattle firm. The contract covers 35 miles from Rock to Bull creek. Construction is to begin within two weeks.——The International Mining & Milling Co. will expend $25,000 in machinery to work three miles of leased ground it has near Lillooet. The property was recently examined by W. S. Reinbold, who is very sanguine of profitable results. The office of the company is in Everett, Washington.

Rossland, August 27.

ONTARIO

The City of Cobalt company forwarded another 30-ton shipment of concentrate to the smelter recently. The operators are stoping on four levels and treating about 40 tons per day at the Northern Customs Co.'s concentrator. The ore assays 25 to 30 oz. silver per ton.——The McKinley-Darragh has declared the regular 3% quarterly dividend with a 2% bonus payable October 1. This makes a total of 15% for this year.——The Porcupine Mine Owners' Association has been formed to maintain a publicity bureau for the camp and protect investors from becoming interested in 'wild-cat' stocks.

CHINA

(Special Correspondence).—There are valuable deposits of stibnite and antimonial oxide near the city of Changsha, and F. A. Schiertz, representing the Allis-Chalmers Co., is superintending the erection of furnaces at this city for the treatment of these ores. The government controls the antimony mines, and has a monopoly of the business. Recently a plant to produce arsenious acid from sulphide ore was built at Hankow by Scharz-Gaumer & Co., but it was not a success and is idle. The only metallurgical establishment in operation near Hankow, aside from the Han Yang Steel Works, is the concentrating mill of Carlowitz & Co. This antimony-lead smelter, owned by the same firm, is now closed. The concentrating mill includes a system of crushers, trommels, jigs, and vanners. The concern is extremely conservative and dislikes publicity. In this plant 45 tons of ore are treated each 10 hours—the working day. The ore contains lead and zinc carrying silver. The concentrate is shipped to Germany.

Hankow, August 1.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. S. HERZIG has been at Reno, Nevada.

H. D. MCCASKEY has been in San Francisco.

A. C. VEACH was in San Francisco last week.

CHARLES JANIN has gone to Bakersfield, California.

W. E. THORNE has left San Francisco for Dawson, Yukon Territory.

W. MURDOCH WILEY left San Francisco for New York last week.

HOWARD D. SMITH will leave San Francisco for London, September 5.

S. BRADSHAW JACOBS is agent for the A. S. & R. Co., Pachuca, Mexico.

J. S. JOHNSON is with the Compania de Sta. Gertrudis, Pachuca, Mexico.

R. B. BRINSMADE is studying mining methods in the anthracite coalfields.

FRED T. WILLIAMS is at Big Pine, California, making a mine examination.

R. C. SPECHT is at present sampling placer ground in Shasta county, California.

HENRY D. BODDINGTON has gone from El Paso, Texas, to Philadelphia, Pennsylvania.

J. P. SMITH has gone to Cosala, Sinaloa, Mexico, to take charge of the Nuestra Señora mine.

ROBERT MUSGRAVE is at Sultepec, Mexico, for the Exploration Company of England and Mexico.

WALTER HOWARD CRAWFORD has returned to Boston after spending the summer at the sea shore.

EDWIN E. CARPENTER is now at Guanajuata, Mexico, in the interest of the Just Extraction Company.

H. H. LANG, superintendent for the Kendall Gold M. Co., Kendall, Montana, has returned from California.

C. E. ALLEN, of the United States Smelting, Refining & Mining Co., visited Judith Basin, Montana, last week.

GEORGE OATES ARGALL is to be married at Denver, September 7, to RUTH BOEHMER, daughter of MAX BOEHMER.

JAMES BREEN, of Spokane, principal owner of the Cumberland mine, at Maiden, Montana, was at the property last week.

WILLIAM F. JONES is making a geologic examination of the Carbon Hill Coal Co.'s properties at Carbondale, Washington.

EUGENE B. RAIL, one of the California pioneers well known in connection with early mining on the Comstock lode, died at San Francisco August 29.

J. A. CARPENTER has resigned as professor at the Mackay School of Mines and is assayer and surveyor for the West End Consolidated at Tonopah, Nevada.

W. L. WATTS, formerly connected with the California State Mining Bureau, was married August 7, at Los Angeles, to the widow of the late JAMES STERLING.

JUAN FELIX BRANDES has returned to California from Paris by way of Chihuahua, Mexico. He will be in Denver at the end of this month going from there to Paris again.

A. BEMENT was married August 23 to Miss Eva Henderson, at Berkeley, California. While on their wedding trip last week both Mr. and Mrs. Bement were badly injured by being thrown from a stage on Mt. Tamalpais. They are recovering nicely.

THE San Francisco Section of the Mining & Metallurgical Society of America will meet following dinner at 6:30, September 5, at the Palace Hotel.

CURRENT PRICES FOR ORES AND MINERALS

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco.

	Min.	Max.
Antimony ore, 50%, per ton	$25.00	$35.00
Arsenic, white, refined, per lb	0.03	0.03½
Arsenic, red, refined, per lb	0.08	0.09
Asbestos, according to length and quality of fibre, per ton	100.00	350.00
Asbestos, lower grades, per ton	10.00	100.00
Asphaltum, refined, per ton	15.00	20.00
Barium carbonate, precipitated, per ton	42.50	45.00
Barium chloride, commercial, per ton	42.50	47.50
Barium sulphate (barytes), prepared, ton	20.00	30.00
Bismuth ore, 10% upward, per ton	75.00	upward
Chrome ore, according to quality, per ton	5.00	15.00
China clay, per ton	15.00	20.00
Cobalt metal, refined, f.o.b. London, per lb	2.50	
Coke, foundry, per 2240 lb	15.00	17.50
Diamonds:		
Borts, according to size and quality, per carat	2.00	15.00
Carbons, according to size and quality, per carat	75.00	100.00
Feldspar, per ton	5.00	25.00
Firebrick:		
Bauxite, per M	175.00	200.00
Magnesite, per M	200.00	250.00
Silica, per M	47.50	
Flint pebbles for tube-mills, per 2240 lb	15.00	25.00
Fluorspar, per ton	8.00	15.00
Fullers earth, according to quality, per ton	10.00	30.00
Gilsonite, per ton	32.50	45.00
Graphite:		
Amorphous, per lb	0.01	0.02½
Crystalline, per lb	0.04	0.13
Gypsum, per ton	2.50	5.00
Infusorial earth, per ton	5.00	15.00
Magnesite, crude, per ton	5.00	7.50
Magnesite, dead calcined, per ton	22.50	27.50
Magnesite, brick (see firebrick).		
Manganese ore, oxide, crude, per ton	10.00	25.00
Manganese, prepared, according to quality, per ton	45.00	125.00
Mica, according to size and quality, per lb	0.05	0.30
Molybdenite, 95% MoS_2, per ton	400.00	500.00
Monazite sand (5% thoria), per ton	150.00	200.00
Nickel metal, refined, per lb	0.45	0.60
Ochre, extra strength, levigated, per lb	0.02½	0.03½
Platinum, native, crude, per oz	20.00	25.00
Quicksilver, per flask (75 lb.)	45.00	48.00
Scheelite (see tungsten ore).		
Sulphur, crude, per ton	15.00	25.00
Talc, prepared, according to quality, per ton	20.00	50.00
Tin ore, per ton	250.00	400.00
Tungsten ore, 65%, per ton	475.00	525.00
Vanadium ore, 15%, per ton	120.00	150.00
Wolframite (see tungsten ore).		
Zinc ore, 50% up, per ton	15.00	20.00
Zinc dust, 90% minimum, per 100 lb	8.50	9.50
Zinc oxide, per 100 lb	7.50	8.50

JOPLIN LEAD AND ZINC PRICES

The *News-Herald* figures for the week ended August 20 are as follows. The zinc-ore surplus was cut down more than 2000 tons last week, blende selling at $41 per ton on a 60% basis. The high price was $44. Calamine sold for $20 per ton on a 40% basis, the record being $26. Lead ore averaged $50 per ton, with pig lead quoted at $4.32½ and spelter $5.15 per hundred. The total production of the district was blende, 12,821,035 lb., valued at $246,238; calamine, 1,117,720 lb., $13,969; and lead, 1,409,635 lb., $35,052.

COMMERCIAL PARAGRAPHS

T. H. Proske has just shipped a D 24 Ajax drill sharpener to the Mijnbouw Maatschappij Sintoeroe at Sambas, Dutch Borneo.

The Cleveland Rock Drill Co., Cleveland, Ohio, advises that The Smith-Booth-Usher Co., of Los Angeles has been appointed as one of its agents.

Merrill precipitation processes and presses are to be installed at the Santa Gertrudis, Pachuca, Mexico, having been selected after a series of tests conducted by Godfrey D. Doveton.

TABLE OF CONTENTS

EDITORIAL

BANKING apparently has no great attraction for Mr. George E. Roberts, who has resigned as president of the Commercial National at Chicago to resume his old position as Director of the Mint. This is an excellent appointment.

CONSERVATION is the topic of the hour at St. Paul this week, where the second annual session of the Conservation Congress is being held. With a list of speakers including Mr. Taft, Mr. Roosevelt, Mr. Pinchot, Mr. Garfield, Mr. Hill, and Governors too numerous to mention, it is no wonder that the Congressional investigating committee postponed consideration of the Pinchot-Ballinger matter. Several Western Governors withdrew, finding that the plan of turning over to each State the public lands within its border was decidedly unpopular. Mr. Roosevelt criticised this plan severely, and who, familiar with Western political history, shall say his strictures were not well founded? The time may come when the trusteeship may be safely transferred to the States, but it is becoming increasingly clear that first steps, at least, must be taken by the Federal Government. Mr. Taft's contribution to the discussion was notably informing and judicial. His demand for specific criticism and suggestions, correctly voices the need of the hour and leads to hope that important advances may be made at the next session of Congress. Popular objection to the attitude of the Administration in conservation matters has been less to the President's legislative program, which is sane and constructive, than to his choice of advisers and assistants in administration.

A RECENT writer in the *Atlantic Monthly* has contrasted delightfully Jonathan Edwards, who went as a missionary to the Indians in such spirit that "our sympathy goes out chiefly to the Indians," with Dr. W. T. Grenfell, who likes Labrador and tells of it so enthusiastically that he "fires the minds of growing boys with the desire to run away and be missionaries themselves." The same contrast is reflected in the story Mr. J. A. MacDonald tells in this number of the young engineer disgusted with Mexico, as compared with his own enthusiastic account of summer travel in that country. Mr. MacDonald writes with a pen touched with *simpatio*. Hardships disappear and the rough trail is made smooth. Snakes vanish and even 'jiggers,' it is pointed out, are small if pestiferous, and may be cured "by bathing in coal oil." We hear the song of the *cuitacche* and are fired with ambition to start at once in search of the lost Gloria Pan mine. It must be easy to find! All this, as Mr. MacDonald

says, is the value of temperament. Would that the schools did more to develop it in the young men who go out to run mines. There would be fewer failures, since on the outpost of civilization the man in command must furnish not only technical knowledge but inspiration for his whole force. An ounce of optimism is sometimes worth as much as a ton of dynamite. We commend Mr. MacDonald's article to all who retain any of the spirit of adventure.

Bureau of Mines and the Director

The President has appointed Mr. J. A. Holmes to be the head of the Bureau of Mines and thus a vexatious controversy has been settled. We congratulate both the men of the Bureau and Mr. Holmes. His administration we believe will be an excellent one, and we look forward confidently to the disappointment of his enemies who feared in him a Director 'unfriendly' to the Geological Survey. In our judgment there never was any foundation for this fear. The whole contest has been as disturbing and harmful as it was unnecessary. Mr. Holmes is a Southerner by birth, a graduate of Cornell University, and a gentleman who, as professor of geology in the University of North Carolina, as State Geologist of that State, as Chief of the Department of Mines and Metallurgy at the Louisiana Purchase Exposition, and as Chief of the Technological Division of the U. S. Geological Survey, has displayed signal ability. He is far seeing, and tactful. He has the confidence of both men and operators in the coalfields and, while less well known among metal miners, has many sturdy friends throughout the West. The new Bureau, to be successful, must be the servant of all. It does not belong to the men, neither is it the peculiar property of the operators. Both coal and metal mining problems must be studied by its officers. It must be free from sectionalism or partisanship, and it must be kept on a high plane as regards scientific accuracy. It is the province of the Bureau to get at the facts as regards safety and waste in mining, and it may well leave to others responsibility for using that knowledge to remedy evils. It may be, and probably is, true, that the mine-run system of payment for coal mining increases waste and decreases safety. That is a proper matter for investigation and report by the officers of the Bureau; but whether the system must none the less be maintained, will be determined by economic conditions and is a matter for negotiation between the operators and men concerned. The Bureau will be responsible only for ascertaining and publishing the facts so that men, operators, and public shall be informed. It is not the province of its officers to work out a flow-sheet for some Congressman's mill, nor for the friend of some Congressman; but it will do a useful work if it continue, for example the studies of colloids begun by Mr. H. E. Ashley, and indicate the possible metallurgical uses of the data, as we understand Mr. Ashley, now transferred to the Bureau of Standards, is to show their relation to the ceramic industries. The metallurgists expect help on the deeper problems of chemistry and physics. They are abundantly able to make practical application of the material as the Bureau furnishes it to them. What we need is fundamental science studied in the light of the needs of the industries; something of that attention to first principles and systematic research that has enabled German industries to grow so notably and so rapidly. The new Director has a wide field, a magnificent opening, and the hearty support of the mining profession. We confidently anticipate that he will measure up to his opportunity and that the new bureau itself will prove to be what its friends have urged it would become, a great agency for the development and betterment of mining and metallurgy.

Transportation in Alaska

Striking figures with reference to the cost of transportation in Alaska have recently been presented by Mr. A. H. Brooks in his report to the Director of the Geological Survey on the 'Mineral Resources of Alaska in 1909.' He estimates that the present annual freight bill for every white man, woman, and child living in the Interior and on Seward Peninsula, is $350. In 1909, 47,000 tons of freight were received at Nome, and, allowing for ocean and inland charges, the total transportation cost was approximately $1,200,000 or nearly 30 per cent of the value of the gold output. In the Yukon basin the total annual charge for freight is between $4,500,000 and $5,000,000; nearly 50 per cent of the value of the gold output. The freight bill for the entire country is estimated at between $7,000,000 and $8,000,000 of which 30 per cent, approximately, represents the cost of ocean haulage. The total shipments from the States to Alaska for the year ended June 30, 1909, were valued at $17,000,000, and the return products at $30,000,000. There is no probability of great decreases in ocean or river charges, and it is worth noting that but for the extensive river system, the interior of Alaska would be as yet, wholly inaccessible. Despite large use of the rivers, freight on general merchandise to Fairbanks costs $73 to $146 per ton. The rate on lumber is $109.50 per thousand feet, and machinery takes practically merchandise rates. Fairbanks is the most important inland Alaska city, and to many other points rates are much higher. The mining camps near Fairbanks have the great advantage of being connected with it by railway, and yet it is evident that under existing considerations nothing but rich gold ore can be worked. Until better and cheaper transportation is afforded, the interior of Alaska must remain unused and unusable except as man may succeed in mining the richest parts of the placers and bonanza portions of quartz veins.

Yet there is abundant and rapidly accumulating evidence to the effect that the resources of Alaska other than gold are large and well worth development. Mr. Brooks and his associates have presented such complete and consistent proof of this that it is not necessary to cite evidence. Mr. T. A. Rickard in 'Through the Yukon and Alaska,' has shown, as have others, that the country is neither barren nor
